POETRY, CRITICISM, GRAMMAR, and THEOLOGY,

By the Reverend JAMES SCOTT, M. A.

FELLOW of TRINITY-COLLEGE, CAMBRIDGE.

The MATHEMATICAL BRANCHES

By Mr. CHARLES GREEN,

Late OBSERVER at the ROYAL OBSERVATORY, GREENWICH.

NAVIGATION, MARINE AFFAIRS, and NAVAL ARCHITECTURE,

By Mr. WILLIAM FALCONER,

AUTHOR of the SHIPWRECK, and PURSER in the ROYAL NAVY.

BOTANY and GARDENING,

By Mr. JAMES MEADER,

GARDENER to the Right Hon. the EARL of CHESTERFIELD.

And the Other BRANCHES of LITERATURE,

By a SOCIETY of GENTLEMEN, who are Lovers and Encouragers of Science.

VOLUME II.

L O N D O N :

Printed for S. CROWDER, at the LOOKING-GLASS, in PATER-NOSTER-ROW;  
And Sold by all other Bookfellers in GREAT-BRITAIN and IRELAND.

MDCCLXVI.

fructification, as the arum, dracontium, birthwort, passion-flower, &c.

**GYPSOPHILA**, in botany, a genus of plants whose flower contains five oval obtuse spreading petals, with ten subulated filaments topped with roundish antheræ. The fruit is a globose unilocular capsule, opening with five valves, and filled with a number of roundish small seeds.

**GYPSUM**, or **PLASTER-STONE**, in natural history, a genus of fossils naturally and essentially simple, not inflammable nor soluble in water, and composed of small flat particles; which form bright, glossy, and in some degree transparent masses, not flexible or elastic, not giving fire with steel, nor fermenting with or being soluble in acid menstrua, and very easily calcining by fire.

Of these gypsums, some are harder, others softer; and are of several colours, as white, grey, red, green, &c. sometimes distinct, and sometimes variously blended together.

The texture of all the gypsums being ultimately the same, it may be sufficient to observe, that their

origin is plainly from particles of a determinate nature and substance, and of a certain and invariable figure, an oblong, flat, and irregularly angular one. These we sometimes see, as indeed is most natural to them, disposed without order or regularity, into loose, complex, friable masses; at others, they are getting out of their native order, and emulating the structure of other classes of bodies, of which they are indeed properly the basis, and appearing somewhat in the figure of the fibrariæ; and at other times, of the foliaceous composite flakes of the selenitæ: the species which have these structures, are truly varying from the gypsums into those bodies they emulate; for the fibrariæ are only a peculiar arrangement of these very particles, and the selenitæ only more broad flakes of the same, like those of the foliaceous talcs.

The gypsums are much used in plaster, for stuccoing rooms, and casting busts and statues.

**GYPSUM STRIATUM**, striated plaster-stone, the whitish, less glossy tricheria, with short thick filaments. See **TRICHERIA**.

## H.

**H**, The eighth letter of the English alphabet, and sixth consonant.

It is a consonant of the guttural kind, as the throat concurs more to its formation than any other of the organs of speech.

Menage distinguishes two kinds of *h*; the one an aspirate, which is a consonant; and the other a mute, which has no peculiar sound distinct from that of the immediately following vowel or diphthong.

When the *h* is preceded by a *c*, both together often sound like the Hebrew *Ch*, with a point over the right horn, as *charity*, &c.

The *ch* in most words derived from the Greek, and expressed in that language by *χ*, is generally sounded like a *k*, as *echo*, *chorus*, &c. though sometimes softened, as *Chersonefus*.

*Ph* is pronounced like an *f*; as *phrases*, *Philistines*, *phlegm*, &c. most of these words being of Greek, or Oriental original, proper names, &c. and wrote in Greek with a *φ*, and with a *ϣ* in the Hebrew.

*H* in ancient authors we meet with instead of *f*; particularly in the Spanish, where most of the words borrowed from the Latin, beginning with an *f*, take

the *h* instead of it, as *hablari* for *fabulari*, *haba* for *faba*, &c.

The sharp accent of the Greeks, which is the same with our *h*, is frequently changed for an *s*, as *ἀνς*, *sal*, *ἐπρσ*, *septem*, &c.

Anciently *h* was put for *ch*: thus, of *Chlodovicus* was formed *Hludovicus*, as we find in the coins of the ninth and tenth centuries; in process of time the second of the *h*'s being much weakened, the *h* was entirely dropped, and was written *Ludovicus*.

The *h* is sometimes found prefixed to the *c*, as *Hcarolus*, *healendæ*, &c. for *Carolus* and *calendæ*.

*H* also, among the ancients, denotes 200, according to the monkish verse,

*H quoque ducentos per se designat habendos.*

When a dash was added at top, *H̄*, it signified 200,000.

**HABBAKUK**, or the prophecy of Habbakuk, a canonical book of the Old Testament.

There is no mention made in scripture, either of the time when this prophet lived, or of the parents from whom he was descended; but according to the authors of the Lives of the Prophets, he was of the tribe of Simeon, and a native of Bethzacar. As he foresaw the taking of Jerusalem by Nebuchadnezzar, he fled to Ostracin in Arabia, where he lived for some time; but after the Chaldeans had made themselves masters of Jerusalem, and were on their return home, he returned into Judæa, where he employed himself in agriculture; but as he was carrying the reapers their dinner, he is said to have been transported by an angel to Babylon, with what he had provided for his people in the field; which he set before Daniel, who was shut up in the lions den, and was transported back again to Judæa, where he died, before the end of the captivity.

He is reported to have been the author of several prophecies which are not extant; but those that are indisputably his, are contained in three chapters. In these the prophet complains very pathetically of the disorders which he observed in the kingdom of Judæa. God reveals to him, that he would shortly punish them in a very terrible manner by the arms of the Chaldeans. He foretells the conquests of Nebuchadnezzar, his metamorphosis, and death. He predicts, that the vast designs of Jehoiachim would be frustrated. He speaks against a prince (probably the king of Tyre) who built with blood and iniquity; and he accuses another king (perhaps the king of Egypt) of having intoxicated his friend, in order to discover his nakedness. The third chapter is a song or prayer to God, whose majesty he describes with the utmost grandeur and sublimity of expression.

**HABDALA**, a ceremony of the Jews, observed on the sabbath in the evening, when every one of the family is come home. At that time, they light a taper, or lamp, with two wicks at least: the

master of the family then takes a cup with some wine, mixed with fragrant spices; and after having repeated a passage or two of scripture, as for example, "I will take the cup of salvation, &c." Psal. cxvi. and, "The Jews had light and gladness, &c." Esth. viii. he blesses the wine and spices. Afterwards he blesses the light of the fire, and then casts his eyes on his hands and nails, as remembering that he is going to work. The whole is intended to signify that the sabbath is over, and is from that moment divided from the day of labour which follows. For this reason the ceremony is called *habdala*, which signifies distinction.

**HABEAS CORPORA**, in law, a writ issued for bringing in a jury, or such of them as refuse to appear upon the venire facias, for the trial of a cause brought to issue.

It commands the sheriff to have the jurors before the judges on such a day, &c. and is of the same nature in the common pleas, as the *distringas juratories* in the court of King's bench.

**HABEAS CORPUS**, in law, is a writ of two kinds, the one being the great writ of the English liberty, which lies where a person is indicted for any crime or trespass before justices of the peace, or in a court of any franchise, and on being imprisoned, has offered sufficient bail, which has been refused, though the case be bailable; in which case he may have this writ out of the King's bench, in order to remove himself thither, to answer the cause at the bar of that court.

The practice in this case is first to procure a *certiorari* out of the court of chancery, directed to all the justices, for removing the indictment into the King's bench; and upon that to obtain this writ, directed to the sheriff, for causing the body of the party to be brought at a certain day.

The other kind of habeas corpus is used for bringing the body of a person into court, who is committed to any gaol or prison, either in criminal or civil causes; which writ will remove the person and cause from one court or prison to another.

No habeas corpus, or other writ, to remove a cause from out of an inferior court, can be allowed, if the same be not delivered to the judge of the court, before the jury, who are to try the cause, have appeared, and before any of them are sworn, 43 Eliz. c. 5.

The habeas corpus act (31 Car. II. c. 2.) has ordained, that a person may have a habeas corpus from any judge, on complaint made and view of the warrant of commitment (except such person is committed for treason or felony, expressed in the warrant, or some other offence that is not bailable) which habeas corpus must be made returnable immediately; and on producing a certificate of the cause of commitment, the prisoner is to be discharged, on bail given to appear in the court of King's bench the next term, or next assizes, &c.

Persons

## H A B

Persons committed for either treason or felony, expressly mentioned in the warrant, upon a motion made in open court, in the first week of the term, or day of sessions, &c. after commitment, are to be brought to trial; and if they are not indicted the next term or sessions after commitment, on a motion made the last day of that term, they shall be let out upon bail, except it appear on oath that the king's witnesses are not ready; and in case they are not indicted, or tried, the second term after commitment, they shall be discharged.

Judges denying a habeas corpus, shall forfeit 500*l.* and if an officer refuse to obey it, or to deliver a true copy of the commitment-warrant, he forfeits 100*l.* for the first offence.

**HABEAS CORPUS AD PROSEQUENDUM**, a writ for the removal of a person in order to prosecution and trial in the proper county.

**HABEAS CORPUS AD FACIENDUM ET RECIPIENDUM**, a writ issued out of the court of Common-pleas, on behalf of defendants sued in inferior courts, to remove their cause into the said court.

**HABEAS CORPUS AD RESPONDENDUM**, a writ that lies where a person is imprisoned at another's suit, in any prison except that of the King's-bench, and a third person would sue the prisoner there; in which case, this writ will remove such person from the prison where he is, into the King's-bench, to answer the action in that court.

**HABEAS CORPUS AD SATISFACIENDUM**, a writ that lies against a person in the Fleet-prison, &c. to charge him in execution. The delivery of this writ to the warden is sufficient.

**HABENDUM**, in law, a term signifying to have and to hold.

A deed or conveyance has two principal parts; the premises and the habendum. The office of the first is, to express the names of the grantor, the grantee, and the things granted: that of the habendum, to shew what estate or interest the grantee is to have in what is granted. According to lord Coke, the habendum is to limit the estate, so that the general implication, which, by construction of law, passes in the premises, is by the habendum controuled and qualified. Thus, in a lease to two persons, to have and to hold to the one for life, alters the implication of the joint-tenancy in the freehold, which would pass by the premises, were it not for the habendum.

**HABERDASHER**, in commerce, a seller of hats, or small wares.

**HABERE FACIAS POSSESSIONEM**, a writ that lies where one has recovered a term for years in an action of ejectment, in order to put him into possession again.

**HABERE FACIAS SEISINAM**, a writ that lies where a person has recovered land in the king's court, directed to the sheriff, commanding him to give seisin of the land recovered.

## H Æ M

**HABERE FACIAS VISUM**, is a writ that lies in divers cases, as in dower, formodon, &c. where it is necessary to take a view of the lands or tenements in question.

**HABERGION**, a small coat of mail, or only sleeves and gorget of mail, formed of little iron rings, or meshes linked into each other. See the article **GORGET**.

**HABILIMENTS of War**, in our ancient statutes, signify armour, harness, utensils, or other provisions for war, without which there is supposed no ability to maintain war.

**HABIT**, in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act.

**HABIT**, in medicine, denotes the settled constitution of the body, or the habitude of any thing else, as the structure or composition of a body, or the parts thereof.

**HABIT** is also used for a dress or garb, or the composition of garments, wherewith a person is covered; in which sense we say, the habit of an ecclesiastic, of a religious, &c. a military habit, &c.

**HABITUDE**, among schoolmen, the respect or relation one thing bears to another. See the article **RELATION**.

**HABITUDE** is also used by philosophers for what we commonly call habit, or a certain disposition or habitude for the performing or suffering certain things, acquired by repeated acts of the same kind.

**HADDOCK**, the English name of a well known fish of the gadus kind, with a bearded mouth, and three fins on the back: its body is whitish, the upper jaw longest, and the tail a little forked.

**HADE**, among miners, signifies the steep descent of a shaft, or the like passage.

**HÆMANTHUS**, blood-flower, in botany, a genus of plants whose flower is monopetalous, erect, and divided into six linear segments, having a very short angular tube, in which is inserted six subulated filaments, topped with oblong incumbent antheræ. The fruit is a roundish trilocular berry, containing three triquetrous seeds.

The flowers grow in clusters, and are of a beautiful red colour. This genus includes the *dracunculoides* of Boerhaave.

**HÆMATITES**, in natural history, the blood-stone, a kind of mineral, so called on account of its resembling curdled blood, or from its quality of stopping blood.

The word is Greek, *αιματιτης*, and is derived from *αιμα*, blood.

**HÆMATOXYLUM**, logwood-tree, in botany. It grows naturally in the bay of Campeachy, Honduras, and other parts of the Spanish West-Indies; it rises to the height of eighteen or twenty feet, and is generally crooked and deformed; the branches are irregular, armed with strong thorns, and furnished with winged leaves composed of three

or four pair of lobes, which are obtuse and indented. The flowers come in a racemus from the wings of the leaves; they are of a pale yellow colour, each containing five equal and ovated petals, with ten subulated stamina. The fruit is a lanceolated, obtuse, and unilocular capsule, opening with two valves, and contains a few, compressed, oblong seeds.

For the uses of logwood, see the article *Campeachy Wood*.

**HÆMOPTOSIS**, in medicine, a spitting of blood, occasioned by the rupture or erosion of some vessel in the lungs, commonly attended with a cough and pressure on the thorax.

The word is Greek, *αιμοπτωσις*, and is derived from *αιμα*, blood, and *πτυνω*, to spit.

**HÆMORRHAGE**, *Hæmorrhagia*, in medicine, an eruption of the blood from any part of the body.

The word is Greek, *αιμορραγια*, and derived from *αιμα*, blood, and *ρηνυμι*, to burst.

**HÆMORRHOIDAL**; the veins and arteries of the rectum and fundament are so denominated, as being the seat of the hæmorrhoids.

**HÆMORRHOIDS**, *Hæmorrhoides*, the piles, or a discharge of blood from the hæmorrhoidal veins about the anus and rectum.

The word is Greek, *αιμορροεις*, signifying the same thing, and derived from *αιμα*, blood, and *ρεω*, to flow.

Every liberal discharge of blood from the veins of the anus, is not to be accounted excessive and preternatural; but in order to form an estimate of this circumstance, we are carefully to consider the vessels, the habit of body, the strength, the age, and the constitution of the patient; for it frequently happens, that the discharge of a certain quantity of blood proves salutary and beneficial to some; whereas the evacuation of an equal quantity proves hurtful and injurious to others: nor is every hæmorrhoidal discharge, though larger than usual, and excited by the increased quantity and commotion of the blood, to be esteemed a disease; but only such a discharge as continues long, impairs the strength, destroys the appetite, the due digestion of the aliments, nutrition, and the other functions of the body, and consequently lays a foundation for violent chronic disorders.

Every evacuation of blood from the intestinum rectum is supplied from the hæmorrhoidal vessels; but the external hæmorrhoidal vessels rarely flow profusely, but readily degenerate into painful varices, which, when opened, discharge blood, though seldom in large quantities. But the internal hæmorrhoidal vessels, which are ramifications of the splenic branch, and are distributed to the interior substance of the intestinum rectum, and the sphincter ani, together with the small arteries arising from the inferior meseraic vessels, not only discharge a large quantity, but, when suppressed, generate those diseases

which arise from disorders of the liver, spleen, pancreas, mesentery, and intestines.

It is usually agreed, that this salutary evacuation from the veins of the anus, is owing to a difficult circulation of the blood through the hæmorrhoidal veins, in consequence of their perpendicular situation, and its difficult return to the vena portæ and the liver; and that the discharge actually happens when the extremities of the vessels, in the intestinum rectum, are so distended by the blood accumulated in them, as at last to be ruptured.

The cure.—As this disorder may proceed from various causes, so there must be various intentions of cure pursued, and different remedies made choice of.

It frequently happens, that when, in plethoric bodies, the hæmorrhoidal discharge, usual at other times, is for some time stopped, it not only appears again suddenly upon any violent commotion either of body or mind, the liberal use of spirituous liquors, too hot baths, or upon taking medicines increasing the intestine motion of blood, but continues long, and is attended with a large and strong pulse. When this is the case, the first step to be taken is to divert the impetus of the blood; for this purpose venesection in the arm, or an immersion of the arms in a tepid mixture of water and wine, are of singular service: then we are to use such things as check the excessive intestine motion of the sulphureous parts of the blood, especially things of a diluting and refrigerating nature, such as drinking cold water, especially of the chalybeate kind, tincture of roses prepared with spirit of vitriol, a decoction of hartshorn, mixed with citron or lemon juice. When, together with a loss of strength, and an injured state of the nobler functions, a large hæmorrhoidal discharge continues for a long time, and the viscera begin to be tainted, whilst, at the same time, the blood is rather aqueous and serous than fibrous, and of a due consistence; those medicines are highly beneficial which gradually and mildly carry off, by stool, the peccant bilious juices, and, at the same time, invite the humours from the intestinum rectum, to the coats and glands of the other intestines. The most efficacious of these are the preparations of rhubarb, with currants and tamarinds; or, if the body is bilious, with cream of tartar, exhibited in a potion rendered agreeable by an eleosaccharum, prepared with the oil of citron.

In that more obstinate and difficultly cured species of this disorder, which arises from an obstruction, an infarction, or increased bulk, of any of the viscera; such as the liver, spleen, and, in women, the uterus: if there is still any place for the means of relief, such medicines are to be chosen as resolve the obstructions without throwing the humours into too violent a commotion.

Among the principal causes of a too copious hæmorrhoidal discharge, we may justly reckon a want

of due tone in the intestinum rectum, together with its component membranes and vessels: for this reason, such medicines are also to be used as restore the strength of parts too much weakened and relaxed; as the extracts of cascarilla and red saunders.

In order to obtain the designed effect, external applications of an astringent nature are also to be used; such as the decoction of balaustine flowers, red-roses, myrrh, and the Peruvian bark.

In the cure of violent hæmorrhoidal discharges, venesection is to be premised; and the primæ viæ cleansed, either with recent cassia, or the best rhubarb, exhibited in a decoction: then both internal and external medicines, of a corroborative and gently astringent nature, may be safely used.

When a sudden stoppage of the hæmorrhoidal discharge is succeeded by an uneasiness of the præcordia, inflations, restlessness, and difficulty of breathing, it is to be recalled by mild laxatives, emollient clysters, and suppositories.

In no disease is an accurate and cautious regimen more necessary than in this, since, in consequence of a neglect in this particular, the most efficacious remedies will not produce their desired effect.

When the disorder is once removed, due pains are to be taken in order to prevent its return. This intention is most commodiously and effectually answered by venesection three or four times instituted every year; by cleansing the primæ viæ once a month, and by the prudent use of mineral waters, or only of chalybeated milk; and, lastly, all such aliments and laxatives as excite pain, are carefully to be abstained from.

**HAGAI**, a canonical book of the Old Testament, so called from the prophet of that name, who, in all probability, was born at Babylon, from whence he returned with Zerubbabel.

This prophet, by the command of God, exhorted the Jews, after their return from their captivity, to finish the rebuilding of the temple, which they had intermitted for fourteen years. His remonstrances had the desired effect; and to encourage them to proceed in the work, he assured them from God, that the glory of this latter house should be greater than the glory of the former: which was accordingly fulfilled, when Christ honoured it with his presence: for, with respect to the building, this latter temple was nothing in comparison of the former.

**HAGGARD FALCON**, the greenish legged falcon, with a livid back. It is a large species, equal to a full grown hen in size. See the article **FALCON**.

**HAGIOGRAPHIA**, or holy writings, a name given to a particular division of the Old Testament, as containing hymns to God, and moral precepts for the conduct of life. The books distinguished by this term were the Psalms, Proverbs, Ecclesiastes, and the Song of Solomon.

**HAIL**, *Grando*, in physiology, a watery concretion in the form of pellucid white globules, that fall from the air.

It is thought to be drops of rain frozen in their passage through the middle region: or according to the Cartesians, the fragments of a frozen cloud, half melted, precipitated and congealed again.

Hail is of various figures, according to the degrees of heat or cold of the air through which the liquified clouds pass. It frequently attends thunder and lightning; the nitre that contributes to the one, having also a large share in the production of the other.

**HAIR**, *Crinis* or *Capellus*, a sort of tegument for the greatest part of animals. It is found on all parts of the human body, except the soles of the feet and palms of the hands.

Hair properly lives and receives nutriment to distend it like the other parts of the body; however, this growth is of a different kind from that of the rest of the body, and is not immediately derived therefrom, nor reciprocated therewith. It grows like plants out of the earth, or as some plants shoot from the parts of others; from which, though they draw the nutriment, each has its distinct life and œconomy.

Hairs are observed by the microscope to be hollow, and furnished with a multitude of vessels; and, however they appear smooth to the naked eye, the microscope shews them knotted like some sorts of grass, and to send out branches from their joints.

The branching of the hair is pretty visible at the extremities by the help of a microscope; for it is very apt to split, especially if worn too long, or kept too dry; and by the same means it appears like a brush.

Each hair has a little bulbous or oval root in the skin, which is sometimes plucked away with it. The hair is commonly reputed an excrement, and whatever the nature of its nourishment be, it seems to be more simple than the other humours of the body. For long after death, when all the other parts and humours are corrupted, the hair will vegetate.

The size of hair depends on the magnitude of the pores they issue from; if those be small, these are fine; if those be oblong or sinous, the hair is curled. Their length depends on the quantity of the proper humour to feed them; and their colour on the quality of that humour; whence at different periods of life the colour usually differs.

**HAIR'S-BREADTH**, a measure of length, being the forty-eighth part of an inch.

**HAKE**, in ichthyology, the English name of the gadus, with two fins on the back, and the under jaw longest. It grows to two feet or more in length, but is the slenderest of all the gadi.

**HALBARD**, or **HALBERT**, in the art of war,  
4 M

a well known weapon, carried by the serjeants of foot and dragoons.

**HALBERT**, among farriers, is a small piece of iron an inch broad, and three or four inches long, soldered to the toe of a horse's shoe, to hinder a lame horse from treading on his toe.

These halbert-shoes necessarily constrain a lame horse, when he goes at a moderate pace, to tread or rest on his heel, which lengthens and draws out the back sinew, that was before in some measure shrunk.

**HALCYON**, in ornithology, a name given by the ancients to the *Ispida*, or king-fisher. See the article **KING-FISHER**.

**HALCYON-DAYS**, *Dies halcyonii*, in antiquity, a name given to seven days before and as many after the winter solstice; by reason the halcyon, invited by the calmness of the weather, laid its eggs in nests built on the rocks, close by the brink of the sea, at this season.

**HALESIA**, in botany, a genus of plants, whose flower consists of a monopetalous ventricose bell-shaped corolla, with ten subulated erect filaments, topped with oblong obtuse antheræ. The fruit is a corticated oblong bilocular nut, containing two seeds.

**HALLERIA**, in botany, a genus of didynamious plants, whose flower is monopetalous and ringent. The fruit is a roundish berry, with two cells, each containing one hard seed.

**HALF-BLOOD**, in law, is where a man marries a second wife, the first being dead, and by the first venter has a son, and by his second venter has likewise a son, the two brothers in this case are but of half blood; they being issue by different venters; and on that account, lands in fee cannot descend from one to the other; except in case of crownlands, dignities, or estates tail. But half-blood is no impediment to an administration, which may be granted to that as well as to the whole blood, of the effects of an intestate; and the half-blood shall come in for a share of his personal estate, equally with the whole blood, as the brothers by different venters are next of kin in equal degree. 22 Car. II. c. 10.

**HALF-MOON**, *Demi-Lune*, in fortification, a work which is commonly made before the curtain or flanked angle of the bastion: the former generally consists of two little flanks and two faces, which terminate in a salient angle towards the fields; the gorge of the demi-lune is terminated by two lines continued from the counterscarpe of the fosse, that form an entering angle towards the place, about the middle of the curtain. The demi-lune on the flanked angle of the bastion differs only from the former, in that it is formed by a circular line; and hence it takes its name demi-lune.

The moderns make use of good counterscarps to cover the bastions instead of the demi-lunes.

They call a demi-lune what was formerly denominated a ravelin, only that this last work has no flanks, and has two faces terminating in a salient angle towards the field.

A demi-lune is said to be crowned when it is covered by a crowned work: it is in like manner said to be a tenaille, when on the right and left it has two works constructed in a right angle on the flanked angle of the demi-lune, by the prolongation of its two faces, between twenty-eight and thirty fathoms; each of these works having two faces terminating in a salient angle towards the field, and a ditch of nine fathoms that separates them from the demi-lune and counterscarpe.

Lastly, a demi-lune is called a horn-work, when it is counter-guarded by two works that advance in form of a horn towards the country, having before it a little demi-lune, or lunette, that covers the intermediate space betwixt them, and consequently the flanked angle of the demi-lune.

**HALF-SEAL**, that used in the court of chancery for sealing commissions to delegates, upon any appeal, in ecclesiastical or marine causes.

**HALF-TANGENTS**. See the articles **TANGENT** and **SCALE**.

**HALIARDS**, in the marine language, the ropes or tackles by which the sails are hoisted up along the masts or stays of the ship.

**HALL**, in architecture, a large room at the entrance of a fine house and palace. Vitruvius mentions three kinds of halls; the *Tetrastyle*, with four columns, supporting the platform or ceiling; the *Corinthian*, with columns all round let into the wall, and vaulted over; and the *Egyptian*, which had a peristyle of insolated Corinthian columns, bearing a second order with a ceiling.

**HALL**, in old writers, is also used for a mansion-house; and to this day, in many parts of the kingdom, gentlemen's seats are called halls.

**HALLAGE**, a fee or toll paid for cloth brought to be sold in Blackwell-hall, London.

**HALLELUJA**, a word signifying, praise the Lord.

The singing halleluja was a sort of invitatory, or call to each other, to praise the Lord.

**HALO**, in physiology, a meteor, in form of a luminous ring, or circle, of various colours, appearing round the bodies of the sun, moon, or stars.

The word is formed of the Greek *αλως*, or *αλωω*, area.

That around the moon is the most usual, and is called *corona*, crown.

Naturalists conceive the halo to arise from a refraction of the rays of light in their passing through the fine rare vesiculæ of a thin nubicula, or vapour, towards the top of our atmosphere; which account they confirm hence, that a quantity of water being thrown up against the sun, as it breaks and disperses

peres into drops, it forms a kind of halo, or iris, exhibiting the colours of the natural rainbow.

M. Huygens supposes halos, or circles round the sun, to be formed by small round grains of a kind of hail, made up of two different parts, one of which is opaque, and inclosed in the other, which is transparent; which is the general structure observed in hail.

After the same manner he accounts for the parhelia; only that he imagines the icy grains of an oblong figure, and rounding at the ends, like cylinders with round convex tops. Where some of these cylinders are in an erect position, the circle they form will be white, by reason of the reflection of the rays of the sun on the surface of these cylinders. He proceeds to account for the coloured halos and parhelia, from the same hypothesis; and produces an experiment of a glass cylinder, a foot long, having within it an opaque kernel (which was a cylinder of wood), and the ambient space filled with water; this cylinder, being exposed to the sun, and the eye disposed in a proper place, the several successive reflexions and refractions necessary to produce such an effect did plainly appear.

The light which comes through drops of rain by two refractions, without any reflection, Sir Isaac Newton observes, ought to appear strongest, at the distance of about twenty-six degrees from the sun, and to decay gradually both ways, as the distance from him increases and decreases: and the same is to be understood of light, transmitted through spherical hail-stones.—Add, that if the hail be a little flattened, as is often the case, the light transmitted may grow so strong at a little less distance than that of twenty-six degrees, as to form a halo about the sun or moon; which halo, as often as the hail-stones are duly figured, may be coloured; and then it must be made red within by the least refrangible rays, and blue without by the most refrangible ones; especially if the hail-stones have opaque globules of snow in their center, to intercept the light within the halo, as Huygens has observed, and make the inside thereof more distinctly defined than it would otherwise be.

Such hail-stones, though spherical, by terminating the light by the snow, may make a halo red within, and colourless without, and darker in the red than without, as haloes used to be: for of those rays, which pass close by the snow, the rubiform will be least refracted, and so will come to the eye in the directest lines.

HALTER-CAST, among farriers, an excoriation of the pasteron, occasioned by a horse's endeavouring to scrub the itching part of his body near the head and neck, when one of his hinder feet entangling in the halter, he sometimes receives very dangerous hurts in the hollow of his pasteron, by his struggling to disengage himself.

For the cure of this, take linseed oil and brandy of each an equal quantity; shake them together in a bottle till they are well mixed, and anoint the place morning and evening, having first cut away the hair; but care must be taken to keep the foot very clean.

HALTING, among farriers, a limping or going lame, an irregularity in the motion of a horse, arising from a lameness in the shoulder, leg, or foot, which makes him spare the part, or use it timorously.

HALYMOTE, in old law books, signifies a holy or ecclesiastical court. See the article COURT.

HAM, in anatomy, the part behind the knee. See KNEE and LEG.

HAM, in old law writers, a Saxon word used for a home or dwelling place, for a borough and a village, and also for a little narrow slip of meadow.

HAM, in cookery the leg and thigh of a hog seasoned and dried.

HAMADRYADS, *Hamadryades*, fabulous deities revered among the ancient heathens, who were supposed to preside over woods and forests, and to be inclosed under the bark of oaks, &c. and to live and die with the trees they belong to.

The word is Greek, *αμαδρυαδες*, and compounded of *αμα*, together, and *δρυς*, an oak.

HAMBLING, or HAMELLING, in the forest law, is the hamstringing of dogs, or cutting the great tendon called the hamstring.

HAMLE, the name of the eleventh month of the Ethiopian year, beginning on the twenty-fifth of June, old style.

HAMLET, HAMEL, or HAMPSEL, is a small village, or part of a parish.

HAMMER, a well known tool used by mechanics, consisting of an iron head, fixed crosswise upon a handle of wood.

HAMMOCK, among sailors, a piece of canvas about six feet long, and three feet wide, drawn together at the two ends, and hung horizontally under the deck for the sailors to sleep in. In time of battle, they are strongly fastened and laid above the rails on the quarter-deck and fore-castle, to barricade and prevent the execution of small shot.

HAMSOKEN, in old law books, signifies the liberty or privilege a man enjoys in his own house. It is also said to signify a franchise granted to lords of manors, by which they hold pleas, and take cognizance of the breach of that immunity.

HANAPER, or HANPER, in chancery. See HANPER.

HAND, *Manus*, in anatomy; the last part of the upper extremity is divided into the carpus, metacarpus, and fingers, or into the inside, hollow, or palm, and into the outside or back of the hand.

The carpus or wrist consists of eight small, unequal, and irregular bones; and, taken all together, represent

represent a sort of grotto of an irregular quadrangular figure, and connected principally with the basis of the radius.

The metacarpus consists of four bones, one side of which forms the palm of the hand, the other the back of the hand. These bones are long, thicker at the extremities than at the middle, and of an unequal length and bigness. The first is the largest, the rest are lessened by degrees in all their dimensions. The fingers make the third part of the hand, and terminate the whole upper extremity; they are five in number in each hand, called the thumb, the fore-finger, the middle-finger, the ring-finger, and the little-finger. The thumb is the biggest of all the fingers; next to that, the third, called the long-finger; the second and fourth are shorter than the third; the fourth being a very little longer than the second; the fifth is the smallest of all.

Each thumb and finger consist of three pieces, called phalanges; the first of which is longer and thicker than the second; and the second than the third.

The carpus is the basis and center of all the motions of the hand, except that of rotation: by means thereof we can bend the hand in all directions, but with more ease towards the sides and edges, than any other way.

The radius is in a manner the handle of the hand; and it is chiefly by means thereof that we can move the hand reciprocally as on the axis, turning either edge of it towards the body. This motion is termed pronation, and when the cubital or small edge is towards the body, it is termed supination. In the natural and most ordinary situation of the hand, the palm is turned towards the body, and not the edges.

The ulna supports the handle of the hand, without being itself articulated with the hand.

All the bones of the carpus, metacarpus, and fingers, are crusted over with cartilages.

HAND, in the manege, a measure of four inches, or of a clinched fist, by which the height of a horse is computed. Thus a horse of war should be sixteen hands high.

HAND is also used for the division of a horse into the fore and hind parts. The parts of the fore-hand are the head, neck, and fore-quarters; and those of the hind-hand include all the other parts of his body.

HAND is likewise used for the horseman's hand. Thus, spear-hand, or sword-hand, is the horseman's right hand, and bridle-hand is his left hand.

HAND-BREADTH, a measure of three inches.

HAND-HOOK, an instrument used by smiths to twist square iron.

HAND-SCREW, an instrument more usually called a jack. See the article JACK.

Harmonical HAND, in music, a name given to the ancient diagram. See DIAGRAM.

*Imposition of HANDS*, the ceremony of laying the hands on the head of a person to be ordained. See ORINATION.

HANDS, in heraldry, are borne in coat armour dexter and sinister, that is, right and left, expanded or open. These are the most necessary parts of the human body, as they serve to express all sorts of actions, and even our very thoughts and designs; thus joining of hands is an universal token of friendship, and clapping of hands a general mark of applause.

HANDING *the Sails*, in the sea-language, the same as FURLING, which see.

HANDSPIKE, a sort of bar used to heave the windlass round at the time of weighing the anchor. It is also used as a lever on many occasions. See the article WINDLASS.

HANKS, in the marine, certain wooden rings fixed upon the stays of a ship, to which the stay-sails are fastened in different places, as a curtain is fastened to the rings which run upon its rod: by these the sails are easily extended upon the stays to their utmost stretch.

HANPER, HANAPER, or HAMPER, an office of the chancery, answering to the fiscus of the Romans.

HANSE, or HANS, a company of merchants united for the promotion and advantage of trade.

HANSE-TOWNS, port-towns of Germany, of which Lubec and Hamburg were the chief. They were formerly all of them imperial cities, confederated for their mutual defence, and the protection of their trade.

HAPPINESS, among philosophers, consists in the enjoyment not only of the goods of the body, as health, strength, neatness, decency, &c. but also of the more refined goods of the mind, as knowledge, memory, taste, and especially moral virtues, magnanimity, fortitude, benevolence, &c.

HAQUEBUT, HAGBUT, HARQUEBUSS, or ARQUEBUSE, a kind of fire-arm.

The word is French, *arquebuse*, and derived from the Italian *arco*, a bow, and *busio*, a hole; on account of the touch-hole at which the priming is put, and as it succeeded to the ancient bow.

HARANGUE, a speech made by an orator in public.

It is frequently used for a pompous and prolix declamation.

HARBINGER, an officer of the king's household, having four yeomen under him, who ride a day's journey before the court, when it travels, to provide lodgings, &c.

HARBOUR, a place where ships may ride safe at anchor, chiefly used in speaking of those secured by a boom and chain, and furnished with a mole. See BOOM, CHAIN, and MOLE.

HARDENING, the act of communicating a greater degree of hardness to a body than it had before.

Steel and iron are hardened and tempered divers ways, as by the hammer; quenching it, when hot, in cold water; case-hardening, &c.

*Case-HARDENING* is a lesser degree of steel-making, and performed by baking razors, files, knife-blades, &c. in a kind of oven, and laying over them a strata of powdered charcoal, hoofs, horns, &c. so as to exclude the air; and thus by baking to give a coat of steel to these instruments some depth below their surface.

Others cover the iron or steel all over with a composition of an equal quantity of powdered horn, bay-salt, and stale urine, or white wine vinegar, well mixed together, and then wrap it up in loam or plate iron, and bring the whole to the fire to a blood-red heat, and no higher; and, lastly, take it out and quench it.

*HARDNESS*, in philosophy, that quality in bodies, whereby their parts mutually cohere together, so as not to give way to an external impulse, nor yield inwards, without breaking. Hardness in this sense is in contradistinction to softness. See the article *ATTRACTION of Cohesion*.

*HARDS*, or *HURDS*, the coarser part of hemp or flax, separated from the fine. See the articles *HEMP* and *FLAX*.

*HARDY SHRUBS*, among gardeners, are those which endure the austerity of the winter.

The two hardiest shrubs we are possessed of, are the ivy and box; these stand the severity of our sharpest winter unhurt, while other shrubs perish, and trees have their solid bodies split and torn to pieces. In the hard winter of the year 1683, these two shrubs suffered no injury any where; though the yews and hollies, which are generally supposed very hardy, were this winter in some places killed, and in others stripped of their leaves, and damaged in their bark. Furze bushes were found to be somewhat harder than these, but they sometimes perished, at least down to the root. The broom seemed to occupy the next step of hardiness beyond these; this lived where the others died; and where even this died, the juniper shrubs were sometimes found unhurt. This last is the only shrub that approaches to the hardiness of the box and ivy, but even this does not quite come up to them; for while they suffer nothing in whatever manner they are exposed, the juniper, though it bears cold well under the shelter of other trees, yet cannot bear the vicissitudes of heat and cold, inasmuch that some juniper shrubs were found half dead, and half vigorous; that side which faced the mid-day sun, having perished by the successive thawings and freezings of its sap; while that which was not exposed to the vicissitudes of heat, had bore the cold perfectly well. Such shrubs as are not hardy enough to defy the winter, but appear half dead in the spring, may often be recovered by Mr. Evelyn's method of beating their branches with a slender ha-

zel wand, to strike off the withered leaves and buds, and giving a free passage to the air to the internal parts. Where this fails, the method is to cut them down to the quick; and if no part of the trunk appears in a growing condition, they must be taken off down to the level of the ground. *Phil. Transf.* N<sup>o</sup>. 165.

*HARE*, in zoology, an animal of the lepus kind, distinguished by its abrupt tail and black eyes. It greatly resembles the rabbit, but is larger, and somewhat longer, in proportion to its thickness; and its ears are remarkably long, being always in a position to receive the least sound, and moveable with surprising ease.

*HARE-LIP*, *Lebium Laporinum*, in surgery. See the article *LIP*.

*HARIOT*, or *HERIOT*, in law, a due belonging to a lord at the death of his tenant, consisting of the best beast, either horse, ox, or cow, which he had at the time of his death; and in some manors, the best goods, piece of plate, &c. are called hariots.

*HARLEQUIN*, a buffoon or merry-andrew; but is now used for a person of extraordinary agility, dressed in party-coloured cloaths, the principal character in a pantomime entertainment. See the article *PANTOMIME*.

*HARMONIA*, in anatomy, a species of articulation, being a kind of symphysis intended for absolute rest. See the article *ARTICULATION*.

*HARMONICA*, or, as it is often improperly called, *ARMONICA*, among musicians, is an instrument composed of musical glasses.

*HARMONICAL ARITHMETIC*, that part of arithmetic which considers musical intervals, expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

*HARMONICAL COMPOSITIONS*, in a general sense includes both harmony and melody, that is, of music or songs, both in a single part, and in several parts.

*HARMONICAL INTERVAL*, in music, denotes the difference of two sounds, which is agreeable to the ear, whether in consonance or succession; and are, therefore, the same with concord. See the articles *CONCORD* and *INTERVAL*.

*HARMONICAL PROPORTION*. See the article *PROPORTION*.

*HARMONICAL SERIES*, a series of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make an harmonical series: such is 30 : 20 : 15 : 12 : 10. Or, if every four terms immediately next each other are harmonical, it is also a continual harmonical series, but of another species, as 3, 4, 6, 9, 18, 36, &c.

*HARMONICAL SOUNDS*, an appellation given, by Mr. Sauveur, to such sounds as always make a

determinate number of vibrations, in the time that one of the fundamentals, to which they referred, makes one vibration.

**HARMONICS**, *Harmonica*, a division of the ancient music. It considers the differences and proportions of sounds with respect to gravity and acuteness, in contradistinction to rhythmica or metrica.

**HARMONY**, in music, the agreeable result of an union of several musical sounds, heard at the same time.

The word is Greek, *αρμογια*, and *αρω*, to fit or adapt.

As a continued succession of musical sounds produces melody, so a continued combination of them produces harmony.

**HARMONY** is sometimes applied to a single voice, when sonorous and soft; or to a single instrument, when yielding a very agreeable sound.

**HARMONY** also denotes a certain agreement between the several parts of a discourse, which renders the reading thereof agreeable.

**HARMONY**, in architecture, an agreeable relation between the parts of a building.

**HARMONY**, in painting, both in the composition and colours of a picture: the former denotes the connexion between the figures, with respect to the subject of a piece: in the colouring it denotes the agreeable mixture of different colours. M. de la Chambre derives the harmony of colours from the same proportions as that of sounds. On this principle he lays down green as the most agreeable colour, corresponding to the octave; red to a fifth; yellow to a fourth, &c.

**HARMONY of the Spheres**, a sort of music much talked of by many of the philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets.

**Pre-established HARMONY**, a celebrated system of M. Leibnitz, whereby he accounts for the communication between the soul and body.

Philosophers universally held, that the soul and body act physically on each other. Des Cartes first shewed that the heterogeneity of their nature did not admit of such real union, and that they could only have an apparent one, of which God is the mediator. M. Leibnitz, unsatisfied with either of these hypotheses, established a third. A soul is said to have a certain series of thoughts and desires; a body, which is only a machine, is to have a certain series of motions, that are determined by the combination of its mechanical disposition with the impressions of external objects.

If now a soul and body are so framed that the whole series of desires and motions of each exactly correspond, this soul and body will have a relation to one another, not by any actual union, but by the constant and perpetual correspondence between the actions of both. Now God puts together this

soul and body, which had such an antecedent correspondence, such a pre-established harmony. And so of other souls and bodies that have been or ever will be joined.

The same principle he extends to the kingdoms of nature and grace, to account for the apparent communication betwixt them, and to make physical and moral evil correspond. See *Leibn. Essais de Theodicée*.

**HARNESS**, the furniture put upon a horse to draw in a coach, or other wheel carriage.

**HARNESS-GALLS**, swellings or soreness on the breasts of coach horses, occasioned by the galling of the harness, especially in rainy weather.

To cure this, first shave off the hair about the fore very close, and rub the whole breast with a lather of water and black sope; then wash that part of the breast which is usually covered with the petrel, with salt-water, suffering it to dry of itself. If the hardness of any part of the harness occasions the galling, take it away, or cover it with little bolsters.

**HARP**, a musical instrument of the string-kind, of a triangular figure, and held upright between the legs, to be played upon with the fingers or nails.

The word is variously derived; some derive it from the High-Dutch *harpff*; others from the Saxon *herra*; both signify the same thing.

**Bell HARP**, a musical instrument of the string-kind; thus called from the common players of it swinging it about as a bell on its bias.

It is about three feet long; its strings, which are of no determinate number, are of brass or steel wire, fixed at one end, and stretched across the sound-board, by screws fixed at the other end. It takes in four octaves, according to the number of strings, which are struck only with the thumbs, the right hand playing the treble, and the left the base; and in order to draw the sound the clearer, the thumbs are armed with a little wire-pin. This may perhaps be the lyra or cythara of the ancients; but we find no mention of it under the name it now bears, which must be allowed to be modern.

**HARPIES**, *Harpyæ*, *αρπυιαί*, in antiquity, rapacious impure sorts of monsters, of the bird-kind, described by Virg. *Æn.* III. The ancients looked on the harpies as a sort of genii.

There were three harpies, Aello, Ocypete, and Celæno; which last Homer calls Pedarge.

**HARPINEER**, or **HARPONEER**, the person who manages the harping-iron.

**HARPINGS**. See the article **SHIP-BUILDING**.

**HARPING-IRON**, or **HARPOON**, a large spear or javelin, made of forged iron, and five or six feet long; it is fastened to a line, and used in the whale fishery.

# H A R

**HARPSICORD**, the most harmonious of all the musical instruments of the string-kind. It is played on after the manner of the organ, and is furnished with a set and sometimes with two sets of keys; the touching or striking of these keys move a kind of little jacks, which also move a double row of chords or strings, of brass or iron, stretched over four bridges on the table of the instrument.

**HARRIER**, a kind of hound, endowed with an admirable gift of smelling, and very bold in the pursuit of his game.

There are several kinds of harriers; some being for the hare, the fox, the wolf, hart, weasel, badger, &c.

**HARROW**, in agriculture, an instrument used by husbandmen to break the clods of earth, and to draw the ground over the seed when sown. It is a sort of wooden drag, made in form of a square, with large iron teeth, or tines, not unlike those of a horse. See **HORSE**.

**HART**, a stag, or male deer, in the sixth year. See **STAG** and **CERVUS**.

**HART**, among sailors, a sort of dead-eye with only one hole in it, used to draw tight the stays. See **DEAD-EYE** and **STAY**.

**HART-ROYAL**, one that has been hunted by the king or queen, and escaped with life; in which case, proclamation is usually made, that none kill or offend him, as being a hart-royal proclaimed.

**HART'S HORNS**, *Cornua Cervi*, in pharmacy, the whole horns of the common male deer, as separated from the head, without farther preparation.

The chemical analysis of hart's horn is sufficiently known: it yields a water highly impregnated with a volatile salt, which is called spirit of hart's horn, with a fetid oil, and a volatile salt by the common distillation in a retort. The remainder in the bottom of the retort, after the distillation is finished, is black; but on being calcined in an open fire, it becomes white and friable, and is what is kept in the shops under the name of burnt hart's horn. Beside these preparations, we use the thin shavings of the horn, which, on long boiling in water, become a jelly: this jelly is nutritive and strengthening; it is sometimes given in diarrhoeas; but a decoction of burnt hart's horn in water is more frequently used for this purpose, and is what is called hart's horn drink.

The salt of hart's horn is a great sudorific, and is given in fevers of many kinds with great success; the spirit has the same and all the other virtues of volatile alkalis, and is used to bring people out of faintings by its pungency, on holding it under their nose, and at the same time pouring some drops of it in water down the person's throat.

**HARVEST**, the time or season that the corn is ripe, and fit to be reaped and taken into barns.

**HARVEST-FLY**, in zoology, a large four-winged fly, of the cicada kind, very common in

# H A T

Italy, and erroneously supposed to be a grass-hopper. See **CICADA**.

**HASSIDEANS**, or **ASSIDEANS**, an appellation given to those Jews who resorted to Mattathias, to fight for the law of God and the liberties of their country.

**HASTA**, among medallists, a kind of javelin, not shod or headed with iron; or rather an ancient sort of scepter, longer than ordinary, occasionally given to all the gods.

**HASTATED LEAF**, among botanists, one resembling the head of an halbert.

**HAT**, a covering for the head, chiefly made of hair, wool, &c. worked, fulled, and fashioned to the figure of the head, and worn by the men throughout the western part of Europe.

Hats are said to have been first seen about the year 1400; at which time they became of use for country wear, riding, &c.

F. Daniel relates that, from the reign of Charles II. in 1449, the use of hats and caps is to be dated, which then began to take place of chaperoons and hoods. In process of time the custom passed from the laity to the clergy, but this was looked upon as a crying abuse, and several regulations were published to prohibit it, enjoining them to keep to the use of chaperoons, made of black cloth, with decent cornets fastened to their hats; and this upon pain of suspension and excommunication. It is true, the use of hats is said to be of a longer standing, among the ecclesiastics of Brittany, by two hundred years; but these were no other than a kind of caps, whence arose the square cap now used in colleges.

*Method of making HATS.*—Hats are made either of wool, or the hair of divers animals, as the beaver, hare, rabbit, camel, &c. The process is much the same in all. The finest hats are made of the pure hairs of the beaver; women tear off the long hair with a knife, like a shoe-maker's knife, and the short hair they scrape off with another kind of knife: then they mix one-third of dry castor to two-thirds of old coat, which is a skin that has been worn some time by the savages. This stuff, so mixed, is carded, and weighed out into parcels, according to the size and thickness of the hat intended: then each parcel is teased with the bow-string to purify it from all filth, and to make the stuff fall precisely together, which is the most difficult part of the work. Thus they form hats of an oval figure, ending at top in an acute angle. With what stuff remains, they strengthen them where they happen to be slender. They purposely make them thicker in the brim near the crown, than towards the circumference, or crown itself. They next harden the hats into closer flakes, by pressing down the hardening leather upon them; after which they are carried to the bason, upon which, laying one hat at a time, they sprinkle it over with water, and mould it: the heat of the fire, the water, and the pressing, embody

embody the stuff into a slight airy felt. The maker, having turned up the edges of this felt round the mould, lays it by and takes another, which, when reduced to the same consistence and form, he joins them together, so as to meet in an angle at top, making only one conical cap.

The next process is to remove the hat to the receiver, or trough, upon the plank or sloping side of which the basoned hat is laid, being first dipped in the kettle: here the hatter rolls and unrolls it, one part after another, first with the hand, and then with a little wooden roller, dipping it from time to time for four or five hours, before it can be properly fulled: in which violent labour the workmen have their hands guarded with thick leather, called gloves. A hat thus wrought is reduced to a proper shape on the block tied down by a commander, and all under this string is left for the brim; then it is set to dry; and when dry enough, it is singed by holding it over a flare of straw, &c. then pounced to take off the coarser nap; then they use the seal-skin; and, lastly, card it to raise the fine cotton; then fitting it to the block, they tie it, cut round the edges, and send it to the dyer's, who boils it in a copper that holds between ten and twelve dozen, with a dye of logwood, verdigrise, copperas, alder-bark, galls, and sumac, for three quarters of an hour at a time, for ten or twelve times successively, taking every hat out after each boiling. The dyer returns it to the maker, who hangs it to dry in the roof of a stove, under which is a charcoal fire; and thus prepares it for stiffening, which is done with melted glue, or gum seneca, smeared over it with a brush, and rubbed in with the hand; then spreading a cloth over the steaming-bason, and sprinkling it with water to raise a strong steam to force in the stiffening, it is placed thereon brim downwards; and when it is moderately hot, the workman strikes gently on the brim with the flat of his hand, to make the jointings incorporate, turning it this way and that, setting it at last on the crown: then it is put on the block, brushed and ironed on the stall-board, and thus finished ready to be lined.

HAT is also used in a figurative sense, to signify the dignity of a cardinal, or a promotion to that dignity.

HATS are also made for women's wear, of chips, straw, or cane, by plating, and sewing the plats together; beginning with the center of the crown, and working round till the whole is finished. Hats for the same purpose are also wove and made of horse-hair, silk, &c.

HACHEL, or HITCHEL, a tool with which flax and hemp are combined into fine hairs. It consists of long iron pins, or teeth, regularly set in a piece of board.

There are several sorts of hatchels, each finer than the other, with which flax and hemp are prepared for spinning. See FLAX and HEMP.

HATCHES, or HATCH-WAYS, certain holes in the decks of a ship, through which the cargo passes into the hold and lower apartments: hatches are also the covers which lie over these holes.

HATCHET, a small light sort of an ax, with a basil-edge on its left side, and a short handle, as being to be used with one hand.

Hatchets are used by various artificers, and more particularly in hewing of wood.

HATCHING, the action whereby fecundated eggs, after a proper time of incubation, exclude their young.

The learned M. Reaumur has obliged the world with an ingenious treatise on the method of hatching chickens by an artificial heat.

HATCHING, or HACHING, in designing, &c. the making of lines with a pen, pencil, graver, or the like; and the intersecting, or going across those lines with others drawn a contrary way, is called counter-hatching. The depths and shadows of draughts are usually formed by hatching.

Hatching is of singular use in heraldry, to distinguish the several colours of a shield, without being illuminated: thus, gules or red is hatched by lines drawn from the top to the bottom; azure, by lines drawn across the shield; and so of other colours. See the articles GULES, AZURE, &c.

HATCHMENT, in heraldry, a name sometimes used for an achievement, or escutcheon over a gate, door, or on the side of an house.

HATCHMENT also signifies the marshalling of several coats of arms in an escutcheon. See the article MARSHALLING.

HATTOCK, a shock of corn containing twelve sheaves: others make it only three sheaves laid together.

HAVEN, a sea-port or harbour. See the article HARBOUR.

HAVER, a term used by country people for oats.

HAUNCH, or HANCH, the hip, or that part of the body between the last ribs and the thigh.

HAUNT, among sportsmen, the place to which game are accustomed to resort: among hunters, it is the walk of a deer, or the place of his ordinary passage.

HAUTBOY, a musical instrument of the wind kind, shaped much like the flute, only that it spreads and widens toward the bottom, and is founded thro' a reed. The treble is two feet long; the tenor goes a fifth lower, when blown: it has only eight holes; but the bass, which is five feet long, has eleven.

HAW, in botany, &c. a common name for the fruit of the white-thorn. See the article MESPILUS.

HAW, in farriery, is a swelling and sponginess that grows in the inner corner of the eye of a horse, so large sometimes as to cover a part of the eye.

The

## H A W

The method of curing it is easily performed by cutting part of it away; but the farriers are apt to cut away too much: the wound may be dressed with honey of roses; and if a fungus or spongy flesh arises, it should be sprinkled with burnt allum, or touched with blue vitriol.

**HAWK**, a synonymous term with falcon, though, by some, restrained to the lesser sort of falcons. See **FALCON**.

**HAWKER**, in commerce, a pedlar, or person that goes about the country selling wares: this name is said to arise from their uncertain wandering, like persons, who, with hawks, seek their game where they may find it.

**HAWKING**, the exercise of taking wild-fowl by means of hawks.

**HAWKWEED**, in botany. See the article **HIERACIUM**.

**HAWSE**, in naval architecture, that part of a ship's bow through which the cable passes, and is drawn into and let out of the ship.

**HAW-THORN**, in botany. See **MESPILUS**.

**HAY**, any kind of grafs, cut and dried, for the food of cattle.

Whatever uplands are designed to be mowed for hay, are to be shut up in the beginning of February, and no cattle suffered to come upon them afterwards; but meadows and marsh lands, where the grafs grows quicker, need not be shut up till April, except the spring be bad; and many farmers feed those meadows which are in danger of overflowing till the first of May, and then shut them up for mowing.

In spring, the stones, sticks, and all other kinds of foulness that lie upon the land, are to be picked up, and the mole-hills all levelled and spread, because they hinder the mowers. If the meadows lie any thing uneven, or if they have been trodden down in winter, they should be rolled all over with a large wooden roller; the mowers will then be able to cut much closer; for this, and the quantity of the hay, will very well answer the trouble.

The time of mowing the grafs must be proportioned to its ripeness; nothing can be more prejudicial to the crop, than the cutting it too soon, because the sap is not then fully come out of the root; and such grafs, when dried into hay, shrinks up almost into nothing. It is very wrong also to let it stand too long, for, when the seed has been ripened, and is shed, the moisture of the sap all dries away out of the stalks, and they become no better than so much stubble; as is plainly seen in those grasses which grow in hedges, and, not being mowed, die away after they have perfected their seeds, and become tasteless and very different from hay. The middle or latter end of June is the general season for mowing; and the red flowers of the honey-suckle beginning to wither, generally give the farmer notice

## H A Z

that the time is coming on. But he may be more assured of this, by the drops or heads of the grafs looking full, bending downward, and looking brown; it is then in the proper state to be cut down.

If there is great plenty of the hay, and it lie thick in the swath, the hay-makers should follow the mowers, and turn the swaths, as they cut them, unless there seems danger of wet weather; but in that case it is better to let them lie in the swath. At night it must be made up into little cocks, and these in the morning must be spread and turned, so that the other side may wither. After this, it is to be made into small cocks again, and the next day spread again, and drawn into long rows, which they call winrows. From these it is to be made up into large cocks, after a little drying; and these large ones, if any wet comes, are to be spread open once again, before they are carried in.

Mowing of land too often, or continuing it too long, is a very great prejudice to it, unless it have the advantage of being fed and renewed by land-floods at times. The farmer who has not this advantage to his lands, should feed them once in two or three years, instead of making hay from them, unless he chuses to lay on manure constantly to keep them in heart. Feeding the hay-lands is the same sort of respite that fallowing is to corn-lands, both very necessary and advantageous.

**HAY-BOTE**, in law, a liberty to take thorns and other wood, to make and repair hedges, gates, fences, &c. by a tenant for life or years.

**HAY-BOTE** is also taken for wood for the making of rakes and forks, used in making hay.

**HAYWARD**, the person who keeps the common herd or cattle of a town.

He is appointed by the lord's court, and his office is to see that the cattle neither break nor crop the hedges of inclosed grounds; he is also to look to the fields, and impound cattle that commit trespass therein.

**HAZARD**, a game on dice, without tables, is very properly so called, since it speedily makes a man, or ruins him.

It is played with only two dice; and as many may play at it as can stand round the largest round table. It is certainly one of the most bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has resolution enough to leave it off in time. See **CHANCE** and **GAMING**.

**HAZLE**, *Corylus*, in botany, a well known plant, which grows common in England in the woods and hedges; it produces male and female flowers, growing at remote distances on the same tree: the flowers are disposed in the form of an amentum; the female flowers are sessile, and included in the germ: they have neither corolla nor pericarpium.

carpium. The fruit is a subovate nut, with a de-  
raded base, and at the top a little compressed and a-  
cuminated.

*Witch-HAZLE*, a name sometimes given to the  
elm. See *ELM*.

*HAZLE-EARTH*, in agriculture, a moderately  
compact earth, much approaching to the nature of  
the chisely soil, and indeed properly a species of it,  
but always containing a large quantity of refin-col-  
oured sand.

*HEAD*, *Caput*, the uppermost or foremost part  
of the body of an animal. When viewed on the  
outside, it is divided into the hairy scalp and the  
face. The hairy scalp covers the upper part of the  
os frontis, the ossa parietalia, the os occipitis, and  
the upper and lower portions of the temporal bones.  
The uppermost part of the hairy scalp is termed the  
vertex or fontanella; the back part, occiput; the  
lateral parts, the temples. See *CRANIUM*.

*HEAD-MOULD-SHOT*, a disease in children,  
wherein the sutures, generally the coronal, have  
their edges shot over each other, so as to compress  
the internal parts. This disease usually occasions  
convulsions, and admits of no cure, unless room  
could be given by a divulsion of the sutures. This  
disorder is opposite to the horse-shoe head. See the  
article *HORSE-SHOE-HEAD*.

*HEAD* is also used for the top or extremity of any  
thing; thus we say, the head of a tree, the head of  
a bone, the head of a nail, &c.

*HEAD*, in architecture, an ornament of carved  
work, or sculpture, frequently serving as the key of  
an arch, or platband, on another occasion.

*HEAD*, among huntsmen, is used for the horns  
of a deer, as a hart, buck, &c. See *ANTLERS*,  
*ROYALS*, *CROCHES*, &c.

*HEAD*, in the military art. Head of a work is  
the front of it next the enemy, and farthest from the  
place, as the front of a hornwork is the distance be-  
tween the flanked angles of the demi-bastions; the  
head of a double tenaille is the salient angle in the  
middle; and the two other sides which form the re-  
entering angles. See the article *FRONT*.

*HEAD*, in painting, sculpture, &c. a represen-  
tation of that part of the human body, whether in  
colours, draught, or creux: if taken from the life,  
or supposed to bear a just resemblance to the per-  
son, it is more properly called portrait. See the ar-  
ticle *PORTRAIT*.

*HEAD-BOROUGH*, the person who is chief of  
the frank-pledge in boroughs, or who anciently had  
the government within his own pledge. See the  
article *FRANK-PLEDGE*.

*HEAD-BOROUGHs*, at this time, are a kind of  
constables. See *CONSTABLE*.

*HEAD-LAND*, in husbandry, is taken to signify  
the upper-part of the land left for the turning of the  
plough.

*HEAD-TIN*, in metallurgy, a preparation of tin-  
ore toward the fitting it for working into metal.  
When the ore has been pounded and twice washed,  
that part of it which lies uppermost, or makes the  
surface of the mass in the tub, is called head-tin:  
this is separated from the rest, and after a little more  
washing becomes fit for the blowing-house.

*Moor's HEAD*, is understood of a horse with a  
black head and feet; the body being usually of a  
roan colour. Among engineers a Moor's head is  
used for a kind of bomb or granado, shot out of a  
cannon. Among chemists it is a cover, or capital,  
of an alembic; having a long neck to convey the  
vapours raised by the fire into a vessel, which serves  
as a refrigeratory. See *ALEMBIC*.

*Dragon's HEAD*, in astronomy, &c. is the as-  
cending node of the moon, or other planet. See  
the article *NODE*.

*HEADs*, a term used by builders for that kind of  
tile which they use to lay at the eaves of a house;  
being the full breadth of a common tile, and but half  
a tile in length. See the article *TILE*.

*HEALING*, in architecture, the covering a roof  
with lead, tiles, slate, or the like.

*HEALTH*, *Hygieia*, *Hygeia*, a proper dispo-  
sition of the body, and all its parts, for performing  
their respective functions; and this consists in a due  
connexion. It is likewise applied to the mind, and  
then it means a just disposition of the rational  
powers and passions to perform their proper actions;  
and this, in a great measure, depends on bodily  
health.

The preservation and restoration of health consti-  
tute the objects of the arts of medicine. The con-  
tinuance of health depends principally on the six  
non-naturals, air, food, exercise, the passions, eva-  
cuation and retention, sleeping and waking. The  
ancients erected a goddess, to whom they supposed  
the care of health to belong: the Greeks worshiped  
her under the name *Tygeia*, and the Romans  
under that of *Salus*. Her temple at Rome was  
on the Mons Quirinalis, where she had a statue  
crowned with medical herbs.

She is represented in medals with a serpent stretch-  
ed on her left arm, and holding a patera to it with  
the right: sometimes she has an altar before her  
with a serpent twisted round, raising its head to  
take something out of the same, with the inscription  
*SAL. AUG.*

*HEAM* denotes in animals the same as after-birth  
or secundines in women.

*HEARING*, *Auditus*, one of the external senses,  
being the act or faculty of perceiving sounds; its  
organ is the ear, particularly the auditory nerve dis-  
seminated through it; its objects are certain vibrations  
of the air. See the article *SOUND*.

The ear and its several membranes, nerves, can-  
als, &c. are vehicles for the reception, modifica-  
tion,

tion, and transmission of sound to the brain, which is the seat of this sense. See EAR.

HEARSE, among sportsmen, a hind of the second year of her age. See HIND.

HEART, *Cor*, in anatomy, a muscular body situated in the cavity of the thorax, on the anterior part of the diaphragm, between the two laminæ of the mediastinum. It is somewhat conical, flattened on the sides, round at the top, and oval at the basis; this last is accompanied with appendices, called auriculæ, and by large blood-vessels; and all these are included in a membranous capsula, named pericardium.

It is hollow within, and divided by a septum, which runs between the edges into two cavities; one of which is thick and solid, called the left ventricle; the other thin and soft, termed the right ventricle; though in their natural situation, the right ventricle is placed more anteriorly than the left. Each ventricle opens at the basis by two orifices, one of which answers to the auricles, the other to the mouth of a large artery; one of which may be termed the auricular orifice, the other the arterial orifice. The right ventricle opens into the right auricle, and into the trunk of the pulmonary artery; the left into the left auricle, and into the great trunk of the aorta. At the edges of these orifices are several moveable pellicles, called valves, of which some are turned inward towards the ventricles, that let the blood enter the heart, but hinder it from going out the same way, and are called triglochinæ or tricuspidæ; others turned towards the great vessels, which suffer the blood to go out of the heart, but hinder it from returning, and are called semi-lunares or sigmoidales. The tricuspidæ of the left ventricle are likewise termed mitræ.

The inner surfaces of the ventricles have thick fleshy productions called columnæ. To the extremities of these columnæ or pillars are fastened several tendinous cords, the other ends are joined to the tricuspidæ. There are likewise other small, short, tendinous ropes along both the edges of the septum, in an obliquely transverse situation, forming a kind of net-work.

The cavities of the ventricles are small deep fossulæ, near each other, with small prominent interstices between. The greatest part of the fossulæ are orifices of the venous ducts.

The fleshy fibres of the heart, especially those of the right ventricle, are either bent into arches, or folded into angles, the latter being longer than the former. The middle of these arches, and the angles of the folds, are turned towards the apex of the heart; and the extremities of the fibres toward the basis. These fibres not only differ in length, but in their directions, which are very oblique in all, but much more so in the long or folded fibres than in the short ones.

Each ventricle is composed of its proper distinct fibres; but the left has many more than the right. By carefully unravelling all the fibres of the heart, we find it to be made up of two bags contained in a third.

The tubes which cross transversely are much more numerous than those which cross longitudinally; which will serve to rectify the false notion about the motion of the heart, that it is performed by a contortion like a screw; that the heart is shortened in the time of contraction, and lengthened in dilatation.

The tricuspidal valves of the right ventricle are three triangular productions, very smooth on that side next the auricle, and on the side next the ventricle several membranous and tendinous expansions, and their edges notched. The valves of the auricular orifice of the left ventricle are of the same structure, and but two in number.

The semi-lunar valves are six in number, three belonging to each ventricle, situated at the mouths of the great arteries, and may be properly enough called valvulæ arteriales.

The auricles are muscular bags, situated at the basis of the heart, one towards the right ventricle the other towards the left, and joined together by an inner septum and external communicating fibres, much like the ventricles; one of them being called the right auricle, the other the left. They are very uneven on the inside, but smoother on the outside, and terminate in a narrow, flat, indented edge, like a cock's comb.

The right auricle is larger than the left, and it joins the right ventricle by a common tendinous opening. It has two other openings united into one, and formed by two large veins, which meet and terminate there, almost in a direct line, called vena cava, superior and inferior: the notched edge of this auricle terminates obliquely in a kind of obtuse point, which is a small production of the great bag, and is turned towards the middle of the basis of the heart.

The whole inner surface of the right auricle is uneven, by reason of a great number of prominent lines, which run across the sides of it, and communicate with each other by smaller lines, which lie obliquely in the interstices between the former.

The left auricle is pretty thick and unequally square, into which the four veins open that are called venæ pulmonares, and which has a distinct appendix belonging to it, like a third small auricle.

Besides the great common vessels, the heart has some peculiar to itself, called the coronary arteries and veins, as in some measure they crown the basis of the heart. These arteries, which are two in number, called the right and left coronaries, go out from the beginning of the aorta, and afterwards spread.

spread round the basis of the heart, to the substance of which they send numerous ramifications. The exterior course of the vein is pretty much the same with that of the arteries; their trunk opens principally into the right auricle, by a particular orifice, furnished with a semi-lunar valve: all the coronary vessels and their ramifications communicate with each other. The pericardium consists of three laminae, the middle and principal of which is composed of very fine tendinous filaments crossing each other in different directions. The external lamina seems to be a continuation of the outer coat of the heart, auricles, and great vessels.

The pericardium is closely connected to the diaphragm, not at the apex, but exactly at that place which answers to the flat or lower side of the heart; the rest of the bag lies upon the diaphragm without any adhesion. The external lamina, or more properly common covering, is formed by the duplication of the mediastinum. The internal lamina is perforated by an infinite number of very small holes, through which a serous fluid continually transudes, in the same manner as in the peritonæum: sometimes, upon dissection, it is of a reddish colour, which may be owing to a transudation of blood through the fine membrane of the auricles.

The heart and parts belonging to it are the principal instruments of the circulation of the blood. The two ventricles ought to be considered as two syringes so closely joined together as to make but one body, and furnished with suckers in contrary directions to each other; so as that, by drawing one of them, a fluid is let in, and forced out again by the other.

The heart is made up of a substance capable of contraction and dilatation. When the fleshy fibres of the ventricles are contracted, the two cavities are lessened in an equal and direct manner, more according to the breadth or thickness, than according to the length of the heart; because the number of transverse fibres is much greater than that of the longitudinal ones.

The fleshy fibres, thus contracted, do the office of suckers, by pressing upon the blood in the ventricles; which blood being forced to the basis of the heart, presses the tricuspidal valves against each other, opens the semi-lunares, and rushes with impetuosity through the arteries of their ramifications, as through so many elastic tubes. The blood, thus pushed on, enters the capillary vessels, and is from thence forced to return by the veins to the auricles, which, like retirements, lodge in the blood returned by the veins during the time of a new contraction, which is termed systole.

The contraction or systole ceases immediately; and in that time the auricles, which contain the venous blood, being contracted, force the blood thro' the tricuspidal valves into the ventricles, the sides of

which are thereby dilated, and this dilatation is called diastole. In this manner does the heart perform the circulation, and that three different ways: the first, and most universal kind of circulation, is that by which almost all the arteries of the body, are filled by the systole of the heart, and the greatest part of the veins evacuated by the diastole.

The second kind of circulation, opposite to the first, is through the coronary vessels of the heart, the arteries of which are filled with blood, during the diastole of the ventricles, and the veins emptied during the systole.

The third kind is that of the left ventricle of the heart, through the venous ducts of which a small quantity of blood passes, without going through the lungs, which is the course of all the remaining mass of blood. *Winslow.*

HEARTS-EASE, in botany. See VIOLA.

HEAT, *Calor*, one of the qualities of the body, opposed to cold. Its presence is known, and its degree measured by the expansion of the air or spirit in the thermometer. It is properly a sensation excited in us by the action of fire, so that it is a particular modification of our minds, and not any thing existing in that form in the body that occasions it. Heat, in the body that communicates it, is only motion; in the mind, a particular disposition of the soul.

Heat, with respect to the effect produced on us, is estimated by its relation to the organ of feeling, no object appearing to be hot, unless its heat exceed that of our bodies.

HEAT, in geography. The diversity of the heat of climates and seasons arises from the different angles, under which the sun's rays strike on the earth's surface.

It is shewn in mechanics, that a moving body striking perpendicularly on another, acts on it with all its force; and that a body striking obliquely acts with the less force, the more it deviates from the perpendicular. Now fire, moving in right lines, must follow the same law, and consequently its action must be measured by the sine of the angle of incidence: and hence fire, striking on any obstacle in a direction parallel thereto, has no sensible effect, by reason the ratio is almost infinite, that is, nothing.

Hence Dr. Halley gives a mathematical computation of the effect of the sun under different climates and seasons, going on this principle, that the simple action of the sun, as all other impulses, is more or less forcible, according to the sines of the angles of incidence, or to the perpendicular let fall on the plane: whence the vertical ray being put for radius, the force of the sun on the horizontal surface of the earth will be to that, as the sine of the sun's altitude at any other time. Hence it follows, that the time of the continuance of the sun's shining being taken for a basis, and the sines of the sun's altitudes erected

erected thereon as perpendiculars, and a curve drawn through the extremities of those perpendiculars, the area comprized therein will be proportional to the collection of the heat of all the sun's beams in that space of time.

Hence it will also follow, that under the pole the collection of all the heat of a tropical day is proportionate to a rectangle of the sine of 23 degrees and a half into 24 hours, or the circumference of a circle; that is, the sine of  $23^{\circ}$  and  $\frac{1}{2}$  being nearly  $\frac{4}{5}$  of radius, as  $\frac{8}{10}$  into 12 hours: or the polar heat is equal to that of the sun continuing 12 hours above the horizon at  $53^{\circ}$  height, than which the sun is not five hours more elevated under the equinoctial.

But whereas the nature of heat is to remain in the subject, after the luminary is removed, and particularly in the air; under the equinoctial, the 12 hours absence of the sun does but little diminish the motion impressed by the past action of his rays, before he rises again: but under the pole, the long absence of the sun for six months, wherein extreme cold obtains, hath so chilled the air, that it cannot, before the sun has got far towards it, be any ways sensible of his presence, his beams being obstructed by thick clouds and perpetual fogs. Add to this, that the different degrees of heat and cold in different places depend, in a great measure, upon the accident of situation with regard to mountains, vallies, &c. the first greatly helping to chill the air by the winds that blow over them, and which come in eddies through the adjoining levels. Mountains sometimes have the effect of a burning mirror on the adjacent plane, and the same effect is sometimes produced from the concave or convex parts of clouds, either by refraction or reflection. And some take these to be sufficient to produce thunder, lightning, &c.

A stony, sandy, or chalky soil reflects most of the rays into the air again, and retains but few, whereby a considerable accession of heat is made to the air; as, on the contrary, black earths absorb most of the rays and return few into the air.

HEAT, in the animal œconomy, known by the several names of natural heat, vital heat, innate heat, and animal heat, is commonly supposed to be that generated by the attrition of the parts of the blood, occasioned by its circulatory motion, especially in the arteries.

To what organs, or operations, the heat of the human body, and other animal bodies, is owing, is hitherto extremely doubtful. The opinions that at present prevail are, 1. That the heat of animal bodies is owing to the attrition betwixt the arteries and the blood. 2. That the lungs are the fountain of this heat. 3. That the attrition of the parts of the solids on one another produce it. 4. That it is owing to the mechanical attrition of the par-

ticles of our fluids. To which opinions Dr. Stevfenson of Edinburgh, adds a 5th, viz. That whole process by which our aliment and juices are constantly undergoing some alteration.

HEATH, in botany. See ERICA.

HEAVEN, *Cælum*, that orb over our heads where the heavenly bodies revolve. Philosophers, divines, and astronomers, lay down divers heavens, as the highest or empyrean heaven, the æthereal or starry heaven, and the planetary heaven.

HEAVEN, among divines, called the empyrean, is the abode of God, and blessed spirits, such as angels, and the souls of the righteous deceased. This in scripture is frequently called the kingdom of heaven, the heaven of heavens, the third heaven, paradise, the new Jerusalem, &c. This heaven is conceived as a place where the Deity is pleased to afford a more immediate view of himself than in the other parts of the universe, where he is likewise present. This makes the beatific vision. The inspired writers, particularly Isaiah and St. John the divine, give us very magnificent descriptions of heaven, its structure, apparatus, and attendance. Eusebius charges Plato with borrowing his description of heaven, in *Dial. de Anima*, from the scriptures, so near is the resemblance.

HEAVEN, in astronomy, called the æthereal and starry heaven, is that immense region where the stars, planets, and comets are ranged.

Sir Isaac Newton has abundantly shewn the heavens to be void of all resistance, and consequently almost all matter, from the planets persisting in their motions without any sensible diminution of their velocity, and the comets passing freely in all directions.

The ancient astronomers assumed as many heavens as they observed different motions therein; all which they supposed solid and spherical. Thus, there were seven heavens for the seven planets; the eighth was for the fixed stars, which they called firmament: Ptolemy adds a ninth, which he called the primum mobile. K. Alphonsus added two crystalline heavens to account for some irregularities in the heavenly motions; and, lastly, an empyrean heaven was drawn over the whole for the residence of the Deity.

The crystalline heavens were supposed to have no stars fixed in them; they encompassed the inferior, starry, and planetary heavens, communicating their motion thereto. The first served to account for that slow motion of the fixed stars, whereby they advance a degree eastward in seventy years: whence the precession of the equinoxes. The second was to solve the phenomena of libration or trepidation.

Eudoxus supposed twenty-three heavens, Calippus thirty, Regiomontanus thirty-three, Aristotle forty-seven, and Fracastor seventy.

The astronomers did not much concern themselves about

## H E B

bout the reality of these heavens, provided they served to account for any of the celestial motions, and agreed with phenomena.

**HEAVING**, among seamen, the act of turning a windlass or capstern by the help of long bars thrust into holes or mortices cut in the bodies of them. See the articles **WINDLASS** and **CAPSTERN**.

**HEAVING a-head**, drawing a ship a-head by heaving in the cable, and thereby making her advance towards the anchor or other place where the cable or rope which draws her onward is fastened.

**HEAVING-DOWN**, the same with careening. See **CAREENING**.

**HEBDOMARY**, a solemnity of the ancient Greeks, in honour of Apollo, in which the Athenians sung hymns to that god, and carried in their hands branches of laurel. The word signifies the seventh day, this solemnity being observed on the seventh day of every lunar month.

**HEBRAISM**, an idiom or peculiar manner of expression in the Hebrew language.

**HEBREW**, or **HEBREW-LANGUAGE**, that spoken by the ancient Jews, and wherein the Old Testament is wrote.

This appears to be the most ancient of all languages in the world, at least we know of none older: and some learned men are of opinion that this is the language in which God spoke to Adam in Paradise, and in which the saints will speak in heaven.

**HEBREWS**, or *Epistle to the HEBREWS*, a canonical book of the New Testament.

Though St. Paul did not prefix his name to this Epistle, the concurrent testimony of the best authors, ancient and modern, afford such evidence of his being the author of it, that the objections to the contrary are of little or no weight.

The Hebrews, to whom this Epistle was wrote, were the believing Jews of Palestine, and its design was to convince them, and, by their means, all the Jewish converts, wheresoever dispersed, of the insufficiency and abolishment of the ceremonial and ritual law. In order to which he undertakes to shew, first, the superior excellency of Christ's person above that of Moses: secondly, the superiority of Christ's priesthood above the levitical: thirdly, the mere figurative nature, and utter insufficiency of the legal ceremonies and sacrifices: and, fourthly, that to forsake the Mosaic law, was not, as the Jews boldly asserted, to apostatize from God, but was their indispensable duty and obligation. These particulars are intermixed with proper inferences and exhortations, all tending to shew the Jewish Christians the unreasonableness, folly, and danger of relapsing into Judaism.

**HECATOMB**, *Hecatombæ*, in antiquity, a sacrifice of an hundred oxen, at as many altars, and by as many priests.

## H E D

Pythagoras we are told sacrificed a hecatomb to the muses, for joy of discovering the demonstration of the 47th Prop. of Euclid's first book.

**HECKLE**. See **HATCHEL**.

**HECKLING of Hemp and Flax**. See **HEMP** and **FLAX**.

**HECTIC**, or **HECTIC FEVER**. See *Slow FEVER*.

**HEDERA**, ivy, in botany. See **IVY**.

**HEDERA TERRESTRIS**, ground ivy, a genus of plants called by Linnaeus *glêchoma*. See **GLECHOMA** and **GROUND IVY**.

**HEDGE**, in agriculture, a fence inclosing a field or garden, made of bushes, boughs, &c. interwoven together.

The word is Saxon, *hegge*, or *hege*, which literally signifies circumference or inclosure.

For quickset hedges, hawthorn is allowed to be the best of all the English shrubs. The best method of raising this for use, is to put the haws into the ground as soon as ripe, and cover them with earth; and by the spring twelvemonth, the shoots will be fit to transplant from the seed-plot into hedge-rows. The crab-tree is a common mixture with the hawthorn in hedges; but grows faster than the hawthorn, and requires cutting to keep the hedge even. The young hawthorns raised from seed always thrive better than those picked up wild in the fields. *Moreton's Northampton*.

The great consideration, in making quick-set hedges, is to bring the plants from a worse soil than that in which it is intended to set them. They must be about the thickness of one's thumb, well rooted and strong, and must be planted about four or five inches out of the ground. If there be a ditch to the hedge, it should be three feet wide at the top, one at the bottom, and two deep; and, if wider, then deeper in proportion.

If the bank be without a ditch, the plants should be set in two rows at a foot distance below one another. The turf is to be laid with the grass side downward on that side of the ditch on which the bank is designed to be made, and some of the best mould must be laid upon it to bed the quick; then the quick is to be laid upon it a foot asunder, so that the end of it may be inclining upwards; and at equal distances of thirty feet, plant an ash, oak, crab, or elm, to grow with the quick. When the first row of quick is laid, it must be covered with mould, and the turf laid upon it as before, and some more mould upon that; so that when the bank is a foot high, another row of sets may be laid against the spaces of the lower quick. These must be then covered as the former, and the bank is to be then topped with the bottom of the ditch, and a dry or dead hedge laid, to shade the under plantation. There should then be stakes-driven into the loose earth quite down to the firm ground, at about two feet and a half distance from each other,

other; oak stakes are accounted the best of all for use, and, the next to this, those of black-thorn or fallow. Small bushes are to be laid below, but not too thick, only to cover the quick from being injured as it shoots.

**HEDYOTIS**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped, with four subulated stamina inserted in the corolla. The fruit is a bilocular capsule, containing a few angular seeds.

**HEDYSARUM**, the French honeyfuckle, in botany, a genus of plants producing papilionaceous flowers. The fruit is a bivalve articulate pod, containing at each joint (which is compressed and roundish) one kidney-shaped seed. There are several species belonging to this genus; that which is best known in our gardens is a biennial plant, and flowers the second year; it sends forth several branching smooth hollow stalks, about two or three feet high; these are furnished with winged leaves, composed of five or six pair of oval lobes, terminated with an odd one; from their base comes out the foot-stalks, which are five or six inches long, sustaining spikes of beautiful red flowers. It blows in June or July, and the seeds ripen in September. They are propagated by sowing the seeds in the spring.

**HEEL**, in anatomy, the hinder-part of the foot. See **FOOT** and **CALCANEUM**.

**HEEL of a Horse**, the lower hinder part of the foot, comprehended between the quarters, and opposite to the toe.

**HEEL of a Mast**, the foot or lower end of it.

**HEEL of a Ship**, the hindmost or aftmost part of a ship's keel.

**HEELING**, in the sea-language, stooping or inclining to one side, either by the pressure of sail at sea, or to clean the ship's bottom, &c. See the article **CAREEN** and **BOOT-TOP**.

**HEGIRA**, in chronology, a celebrated epocha among the Arabs and Mahometans.

The word is Arabic, *bagirah*, which signifies flight.

The event which gave occasion to this epocha was Mahomet's flight from Mecca; the magistrates of this city, fearing this impostor might raise a sedition, expelled him on the 15th or 16th of July, in the year 622, being the 14th year of his assuming the character of prophet, and under the emperor Heraclius.

There is an earlier Hegira in the same year, when Mahomet and his disciples relinquished Medina. Both these hegira's the Mahometan's call hegiran.

**HEIGHT**, *altitudo*, in geometry. See the article **ALTITUDE**.

**HEIR**, *heres*, in law, signifies a person who succeeds another by descent to lands, tenements, hereditaments, being an estate of inheritance, or an

estate in fee; because nothing passes by right of inheritance but in fee.

**HEIR-APPARENT** is a person so called in the life-time of his ancestor, at whose death he is heir at law.

**HEIRESS**, a female heir to one who has an estate in lands, &c. Stealing an heiress, and marrying her against her will, was declared felony by 3 Hen. VII.

**HEISTERIA**, in botany, a genus of plants, whose flower consists of five ovate concave patent petals, with ten filaments topped with roundish antheræ. The fruit is an oblong drupe, depressed at the top, containing an oval obtuse nut.

**HELENIUM**, bastard sun-flower, in botany, a genus of plants, whose flower is compound and radiated; the corollulæ, which form the disc, are numerous and hermaphrodite, of a tubulous form, and quinquedentated at the limb; the female florets which compose the rays, are linear, ligulated, and trifid at the point; the stamina are five slender and very short filaments, topped with cylindrical antheræ; the seeds are single, and placed on a convex naked receptacle.

**HELENIUM** is also used sometimes for *elecampane*. See **ELECOMPANE**.

**HELEPOLIS**, in the ancient art of war, a machine for battering down the walls of a place besieged, the invention of which is ascribed to Demetrius the Poliorcece.

**HELIACAL**, in astronomy, a term applied to the rising or setting of the stars, or, more strictly speaking, to their emergence out of and immersion into the rays and superior splendor of the sun.

A star is said to rise heliacally, when, after being in conjunction with the sun, and so invisible, it gets at such a distance as to be seen before the sun rise; and it sets heliacally, when it approaches so near the sun as to be hid by its rays: so that strictly these are only an apparition and occultation.

The heliacal rising of the moon happens when she is seventy degrees distant from the sun; for the other planets twenty degrees distance is required; and for the stars more or less, according to their magnitude.

To find by the globe the time of the year when any known star or planet will rise or set heliacally: rectify the globe, and bring the star or planet to the east part of the horizon; then see what degree of the ecliptic is elevated above the western horizon, according to the respective arch of vision: then the opposite degree on the horizon, so found, compared with the calendar, will shew you the day of its rising; and for its setting bring the star or planet to the west side of the horizon; observe to the east what degree is elevated equal to the known arch of vision; then, by the opposite degree, will be found the day of its setting.

**HELIANTHEMUM**, dwarf cistus, in botany,

a genus of plants, whose flower hath five roundish patent petals, with a number of erect stamina. The fruit is a roundish or oval capsule of one cell, opening with three valves, and filled with small roundish seeds.

This genus is included among the cistuses by Linnæus.

**HELIANTHUS**, the great sun-flower, in botany, a genus of plants, whose flower is compound and radiated; on the disc is placed a multitude of hermaphrodite cylindraceous florets; the rays are composed of a few very long, spear-shaped, ligulated, female ones; the stamina are five curved filaments, topped with cylindraceous antheræ; the seeds are solitary, oblong, tetragonal, and contained in the cup; the flowers are all yellow, and often more than a foot in diameter.

This genus is the same as the corona solis of other authors, and includes the Jerusalem artichoke which is a species of it.

**HELICE**, in astronomy, is the same with ursa major. See **URSA**.

**HELICTERES**, the screw-tree, in botany, a genus of plants, whose flower consists of five oblong equal petals, which are affixed to the receptacle; the stamina are ten very short filaments, topped with oblong antheræ. The fruit is composed of five unilocular capsules, spirally twisted, and contains many angulated seeds.

**HELIOCARPOS**, in botany, a genus of plants, whose flower hath a tetraphyllous coloured perianthium, including four linear petals, considerably shorter and narrower than the cup; the stamina are twelve filaments, topped with twin incumbent antheræ. The fruit is a pedunculated bilocular capsule, of a turbinated oval figure, bordered with hairs resembling rays, and the seed is oval and solitary.

**HELIOCENTRIC Place of a Planet**, that place or point in the ecliptic, wherein a planet would appear to a spectator placed in the center of the sun.

The word is Greek, and compounded of *ἥλιος*, the sun, and *κεντρον*, a center.

The heliocentric place is the same with the longitude of a planet viewed from the sun.

**HELIOCENTRIC Latitude of a Planet**, the latitude it would appear in at any time to a spectator placed in the sun.

**HELIOCOMETES**, a phenomenon sometimes observed about sun-setting; being a large luminous tail, or column of light, proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

**HELIOSCOPE**, in optics, a sort of telescope, peculiarly adapted for observing the spots, eclipses, &c. of the sun.

The word is Greek, and compounded of *ἥλιος*, the sun, and *σκοπεω*, to view.

There are various apparatuses of this kind: Dr. Hook recommends four reflecting glasses placed in the tube, whereby the force of the rays will be so weakened, as only to strike the eye with a 256th part of their force; and this he prefers to all others.

M. Huygens only blackens the inside of the eye-glass of the telescope, by holding it over the flame or smoke of a lamp, &c. or rather he blackens a piece of plain glass, and holds it between the eye and the object-glass; or, which is best of all, he claps the smoked glass to another, with a rim of thick paper between to keep the black from rubbing off, and fits the two into a frame, to be applied between the eye and the eye-glass. But the best method of viewing this luminary, is by the solar telescope. See **Solar TELESCOPE**.

**HELIOSTATA**, in optics, an ingenious instrument invented by the learned Dr. s'Gravesande; so called from its use, which is to fix, as it were, the rays of the sun in a horizontal direction across the dark chamber, all the while it is in use.

The word is formed from the Greek, *ἥλιος*, the sun, and *στασις*, to stop or fix.

This instrument is an automaton, or piece of clock-work, whose parts are as follow:

A A (plate LXI. fig. 1.) is a frame, about which a metalline speculum S is suspended, moveable about its axis, by means of two small screws a, a. This frame is fixed to the piece C, which being hollow is moveable upon the cylindric shaft P. This pillar is fixed on a triangular base or foot set perpendicularly, by the three screws B, B, B.

On the back part of the speculum is fixed a long cylindric wire, or tail D, in a perpendicular position. By this it is connected to the second part of the heliostata, which is a common thirty-four hour clock, represented at H; the plane of which clock is set parallel to that of the equator in any given place. This clock is sustained on the column FG, in which it is moveable up and down by a thin lamina or plate that enters it as a case, and fixed to a proper height by two screws d, d, at the side. The whole is truly adjusted to a perpendicular situation by means of three screws I, I, I, in the tripod L, L, M, and the plummet Q, whose capsis must answer to the point o beneath.

The axis of the wheel which moves the index NO, over the hour circle, is somewhat large, and perforated with a cylindric cavity approaching a little to a conical figure; and receives the Shank of the said index NO very close and tight, that by its motion the index may be carried round. In the extremity O of the index is a small cylindric piece, with a cylindric perforation to receive the tail t of the fork T, yet so as to admit a free motion therein. In each side of the fork are several holes exactly opposite to each other, in which go the screws r, r, upon

Fig. 2. Heliofata.

Fig. 5.

Fig. 1.

Heliofata.

Fig. 3. Hydrometer.

Fig. 4.

upon whose smooth cylindric ends moves the tabular piece R.

When the machine is to be fixed for use, another part is made use of to adjust it; which is called the positor, and is denoted by the letters VXYZ, *fig. 2.*

The cylinder C is removed with a speculum from the foot P, and the brass column V X put on in its stead, and adheres more strictly to the pin *e*, that it may keep its position while the machine is constituted.

On the top of the column, about X as a center, moves the lever YZ, so that it may be any how inclined to the horizon, and keeps its position. The arm YX may be of any length at pleasure; but the arm XZ is of a peculiar construction, and of a determinate length. To this arm, which extends no farther than y, is a sliding piece Zx, sharp pointed at Z. By this the arm XZ is determined to a given length, the piece Zx being fixed by the screws zx. Upon this arm is drawn the short line ux, by which it may be lengthened in the whole, and is  $\frac{1}{100}$  of the whole length XZ, when shortest. The reason is, this arm is always to increase and decrease in proportion to the secant of the sun's declination to the radius XZ, when shortest; but the radius is to the secant of  $23^{\circ} 30'$ , the sun's greatest declination, as 10000000 to 10904411, or as 100 to 109. Now the reason of this construction of the arm XZ, is to find for any given day the distance of the center of the speculum S from the top l of the style /N, which must ever be equal to the secant of the sun's declination; for it must always be equal to the distance of the top of the said style, l, from the center of the cylinder R in the fork T, and that is always equal to the said secant of declination.

For since the style /N and the fork T are in a position parallel to each other, therefore the middle hole in the sides of the fork being, as they must be, of the same height above the end of the index O, as in the height of the style Nl, it is evident that on an equinoxial day the sun's rays will pass directly thro' the perforation of the piece R, if it be put in a position parallel to the plane of the ecliptic, or that of the clock; and also that the top of the shadow of the said style will fall exactly on the said hole.

In this case, the top of the style is at the least distance from the central point of R, and therefore may be represented by radius; while in any other position above or below, the distance will increase in proportion to the secant of the angle which the rays make with this first or middle ray, that pass by the top of the style, and through the hole R.

Now it may be demonstrated, that on any day of the year, if the clock and its pedestal be so fixed that the line of XII be exactly in the meridian, and that the position of R in the fork be such that the sun's rays go directly through it, and the shadow of

the style's top fall just upon the hole; moreover, if the distance of the center of the speculum S from the top of the style l be made equal, by the positor, to the distance of the central point R therefrom; and, lastly, the tail of the speculum DE passing through R; then if the clock be put into motion, the index NO shall carry about the tail of the speculum, in such a manner, that at all times of that day, when the sun can come upon the speculum, it will reflect the rays constantly in one and the same position and direction all the time without variation.

The machine thus constituted, is placed in a box or case, and set in the window with one side open, exposed to the sun, and all the other parts close; so that when the room is made dark, and the solar microscope fixed to the fore-part of the box in which the heliostat is placed, just against the center of the speculum to receive the reflected horizontal beam, all the experiments of the darkened room are then performed as usual.

This is a very ingenious construction of a solar microscope apparatus, but we fear too expensive and troublesome for common use. However, it is easy to see that this machine is capable of being greatly reduced; since it may be made to answer the end very well without a clock, and the speculum may be glass instead of metal, and all fixed in one pedestal. See the article MICROSCOPE.

HELIOPTROPE, in natural history, a large bluish-green jasper, with red variegations. See the article JASPER.

HELIOTROPIUM, turnsole, in botany, a genus of plants whose flower is monopetalous and saucer-shaped; the tube is the length of the cup; the limb is plane, divided lightly into five segments, and obtuse: the smaller segments stand alternate and are acute; the larger are placed between: the mouth is closed by five prominent squamulae, joined in the form of a star, there is no pericarpium, the calyx remains unaltered, and contains four oval acuminate seeds.

A decoction of common turnsole purges phlegm and bile. It is good against the sting of serpents: the leaves are said to take away warts, ulcers, gangrenes, and scrophulous tumours.

HELIX, in geometry, the same with a spiral line.

The word is Greek, *ελίξ*, a wreath, or winding, and derived from *εἰλεω*, or *ἐλίσσω*, to environ.

HELIX, in architecture. Some distinguish between it and spiral. Daviler says a staircase is helical, when the steps wind round a cylindrical newel; whereas the spiral winds round a cone, continually approaching nearer its axis. Helix also denotes, in architecture, the caulicules or little volutes under the flower of the Corinthian capital, called likewise urillae.

HELIX, in anatomy, the external circle or border of the ear, in contradistinction to the inner pro-

# HEL

protuberance corresponding thereto, called the an-  
thelix. See EAR.

**HELL**, *Gebenna, Tartara, Hades, Infernus*, &c.  
the place of divine punishment after death, in con-  
tradistinction to heaven. See the article HEAVEN.

As all religions have supposed a future state of  
existence after this life, so all have their hell or  
place of torment, in which the wicked are supposed  
to be punished. The hell of the ancient heathens  
was divided into two mansions, the one called Ely-  
sium, on the right hand, pleasant and delightful,  
appointed for the souls of good men; and the other  
called Tartara, on the left, a region of misery and  
torment, appointed for the wicked. The latter was  
only hell in the present restrained sense of the word.  
See the article ELYSIUM.

**HELLEBORUS**, black hellebore, in botany,  
a genus of plants, whose flower is roseaceous, and  
consists of five large roundish obtuse petals, with a  
great number of capillary stamina. The fruit is  
composed of several bicarinate compressed capsules,  
containing a number of round seeds fixed to the sur-  
ture.

The common sort grows naturally in several parts  
of England; but the true black hellebore, or Christ-  
mas flower, grows on the Alps and Apennine moun-  
tains; it is a low perennial plant, without any  
other stalk than the pedicles of the leaves and flow-  
ers; the leaves are divided, quite to the pedicle,  
into seven or eight smooth firm segments, indented  
about the middle to the extremity, and flowers with  
us in January.

Black hellebore root is composed of many thick  
fleshy fibres, black without and white within, of  
an acrid bitterish taste; the smell, while fresh, is  
exceeding strong. This taken inwardly proves a  
cathartic, and is reckoned good in melancholic and  
atrabilarious disorders; it is found particularly ser-  
viceable against obstinate suppressions of the men-  
strual purgations, in plethoric habits, and sanguine  
constitutions, where chalybeates are ineffectual or  
injurious.

*White Hellebore*, in botany. See the article  
VERATRUM.

**HELLENISM**, a sort of Græcism; a phrase  
peculiarly adapted to the genius of the Greek  
tongue.

Hellenism is distinguished from Græcism; in  
that the former is not applied to authors who have  
wrote in Greek, but to those who, writing in  
some other language, use terms peculiar to the  
Greek.

**HELLENISTIC**, or **HELLENISTIC LAN-  
GUAGE**, that spoken among the Hellenists.

**HELM**, in the marine, an engine of wood hung  
on the outside of a ship behind, upon certain goog-  
ings bolted to the stern-post, upon which it re-  
volves, and by its motion directs the course of the  
ship at sea.

# HEM

The helm is composed of two or three parts, viz.  
the rudder, the tiller, and the wheel; this last part  
however is seldom used but in men of war, and the  
largest merchant-ships.

The rudder is that part of the helm which is  
hung on the outside of the stern-post, as before de-  
scribed: in the top of the rudder there is a mortice  
cut, into which is firmly bolted the tiller, which is  
a piece of timber thrust into the rudder to turn it;  
and, lastly, the wheel is employed to move the tiller  
with greater facility from one side to the other, in  
directing a ship.

**HELMET**, an ancient defensive armour worn  
by horsemen, both in war and in tournaments. It  
covered both the head and face, only leaving an  
aperture in the front secured by bars, which was  
called the visor.

**HELONIAS**, in botany, a genus of plants,  
whose flower consists of six oblong equal petals,  
with the same number of stamina. The fruit is a  
roundish capsule, having three cells, each contain-  
ing a roundish seed.

**HELVE**, a term used among country people for  
the handle of a hatchet, pick-ax, mattock, or the  
like.

**HEMEROCALLIS**, day lilly, in botany, a ge-  
nus of plants, whose flower consists of an infundi-  
buliform-campanulated corolla; the tube is short,  
the limb patent, and divided into six reflexed seg-  
ments. The fruit is an oval three-cornered cap-  
sule, containing three cells, which are filled with  
roundish seeds.

This genus includes the lilio-asphodelus of Tour-  
nefort.

**HEMERODROMI**, in Grecian antiquity, cen-  
tinels and guards appointed for the security and pre-  
servation of cities and other places.

**HEMICRANIA**, in medicine, a species of head-  
ach, wherein only one half or side of the head is  
affected.

**HEMICYCLE**, in architecture, is defined by  
Daviler to be an arch forming a perfect semicircle.  
See the articles ARCH and BRIDGE.

To construct such an arch of hewn stone, they  
divide hemicycle into a certain number of equal  
parts, and fashion an equal number of voufoirs,  
which will complete the arch: however, that there  
may be no joint in the middle, where the key-stone  
should be, they always take care that the number of  
voufoirs be an odd one.

**HEMICYCLUM**, in antiquity, a part of the  
orchestra in the ancient theatres.

**HEMICYCLUM** also signified a kind of sun-dial;  
being a concave semicircle, the upper cusp of which  
looked to the north. On the middle of the hemi-  
cyclium stood a style, whereof the point that cor-  
responded to the center of the hemicycle, repre-  
sented the center of the earth; and its shadow, be-  
ing

# HEM

ing projected on the concavity of the hemisphere, which represented the space between the two tropics, pointed out not only the declination of the sun, and the day of the month, but likewise the hour of the day.

**HEMINA**, in Roman antiquity, a liquid measure, which, according to Arbuthnot, was equal to half a wine-pint English measure; its contents being 2,818 solid inches. See the article **MEASURE**.

**HEMIONITIS**, mules fern, in botany, a genus of plants, of which there are several species; the fructifications of this genus are arranged into lines, sometimes branched, often uniting and intersecting one another.

**HEMISPHERE**, *Hæmisphærium*, in geometry, the half of a globe or sphere, when divided into two by a plane passing through its center.

The word is Greek, and compounded of *ἡμῖος*, half, and *σφαῖρα*, a sphere.

The center of gravity of a hemisphere is  $\frac{3}{8}$  of the radius distant from the vertex. It is proved in optics, that a glass hemisphere unites the parallel rays at the distance of a diameter and one third of a diameter from the pole of a glass.

**HEMISPHERE**, in astronomy, particularly denotes one half of the mundane sphere. The equator divides the sphere into two equal parts, called the northern and southern hemispheres, having the north and south poles in their respective zeniths. The horizon also divides the sphere into two hemisphere, the upper and lower, having the zenith and nadir in their respective vertices.

**HEMISPHERE** also denotes a projection of half the terrestrial globe, or half the celestial sphere on a plane, and is frequently called planisphere.

**HEMISPHEROIDAL**, in geometry, an appellation given to whatever approaches to the figure of an hemisphere, but is not exactly so.

**HEMISTICH**, *ἡμιστίχος*, in poetry, denotes half a verse, or a verse not completed.

In reading common English verses, a short pause is required at the end of each hemistich, or half verse.

**HEMITONE**, in the ancient music, what we now call a half note or semitone.

**HEMITRITÆUS**, in medicine, a kind of fever, denoting the same as semi-tertian, returning twice every day.

The word is Greek, and compounded of *ἡμῖος*, half, and *τρίαις*, third or tertian.

**HEMLOCK**. See **CONIUM**.

**Water HEMLOCK**. See **CICUTA**.

**HEMP**, *Cannabis*, in botany, a very useful plant for making cordage, and all things of that kind.

The stalks of hemp grow to be five or six feet high, angular, and covered with a strong tough bark; and clothed with many digitated leaves, each composed of five, six, or seven parts, long and

# HEM

narrow, sharp-pointed and serrated about the edges, the middlemost being longest, set together upon one foot-stalk; they are green above and hoary underneath, and rough in handling. The flowers, in that they call the male, grow towards the top of the stalk in bunches, small and staminous, which perish without bringing any seed, which is produced by the female without any previous flowers.

Hemp is an useful plant, purchased at a dear rate from foreigners, when it might be cultivated among ourselves, to the great benefit of the nation in general. It delights in warm, sandy, or somewhat gravelly soil; but it must be somewhat rich and of a good depth. The best seed is that which is brightest, and retains its colour and substance in rubbing. Three bushels will sow an acre; but the richer the land is, the thicker it must be sown, and the poorer it is, the thinner. The time of sowing it, is from the latter end of March, to the end of April, according as the spring falls out; but the earlier it is sown the better. If it be a dry season, great care must be taken to preserve it from birds.

The first season for gathering it is about Lammas, when a good part of it will be ripe; that is, the light summer hemp which bears no seed, and is called fible-hemp. When it is ripe, the stalks grow white, and the leaves fall downwards, turning yellow at the top; it must then be pulled up, dried, bound up in bundles as big as may be grasped in both hands, and laid by for use. Care must be taken not to break what is left standing, because it is to grow till near Michaelmas before it will be fit to gather: this is usually called karle-hemp. When it is gathered, lay it in the sun three or four days to dry, and then stack or house it till the seed be threshed out.

An acre of hemp, in the best land, commonly yields about two or three quarters of seed, which, with the hemp unwrought, is often worth from 5 to 8l. but if wrought, from 10 to 12l. but the fible-hemp is not worth above half as much as the other.

As to the method of preparing it, after the seeds are threshed out of the heads, and the stalks are laid up in bundles, and steeped in a standing water, the cleaner it is the better; they are fastened to poles, and left to soak about fifteen days; and when the substance of the stalk is almost rotten, the bundles are taken out and well dried. But flax, instead of being steeped in water, is usually exposed alternately to the moist air of the night, and the heat of the sun, by which means it receives a finer colour.

When hemp and flax are well penetrated and afterwards completely dried, they are bruised by handfuls on a block, with a kind of mallet; all the bullen, which is the inward substance of the stem, flies off in shivers, by the force of the blows, and nothing remains in the hands of the beater but the thin

## H E P

thin bark in large threads, through the whole length of the stem. This parcel of threads is afterwards hung on a perpendicular board, and bruised with a wooden beetle, in order to shake out all the little straws that may happen to remain of the bullen. All the gross parts are now separated from the stem, and the threads of the bark receive their perfection from the comb or hatchel. See the article **HATCHEL**.

The refuse of this combing, which consists of all the threads which are too thick, is called tow, for the use of which see the article **TOW**.

**HEN**, *Gallina*, in ornithology, though used in a general sense to signify any female bird, is more particularly restrained to those of the order of gallinæ.

**HEN-BANE**, a plant called by botanists hyosciamus. See **HYOSCIAMUS**.

**HEN-MOULD**, among farmers, denotes a black spongy soil, fitter for grazing than for corn.

In some places, indeed, they give the name of hen-mould to a rich black earth mixed with whitish streaks, which is exceeding fertile.

**HENTING**, among farmers, a method of sowing immediately before the plough, by which, it is pretended, a great deal of charge is saved. See **PLOWING**.

**HENTING FURROWS**, those turned from each other at the bottom, in plowing ridges. See the article **PLOWING**.

**HEPAR**, the liver, in anatomy. See **LIVER**.

**HEPATIC**, in medicine and anatomy, any thing belonging to the liver.

**HEPATIC ALOES**. See **ALOES**.

**HEPATIC VEIN**. See **BASILICA**.

**HEPATIC**, noble liverwort, in botany, a low plant, without any other stalk than the pedicles of the leaves and flower; the leaf is cut, not very deep, into three lobes, entire about the edges; the flower is commonly blue, sometimes reddish or white, hexapetalous, set in a three-leaved cup, with numerous stamina in the middle, which are followed by a cluster of whitish seeds. It is perennial, grows wild on gravelly shady grounds in Germany and other parts of Europe, and flowers in our gardens in March or sooner.

This herb is a mild restraining and corroborant; in which intentions, infusions of it have been drank as tea, or the powder of the dry leaves given to the quantity of half a spoonful at a time.

**HEPATIC**, liverwort, in botany, a species of moss, consisting of numerous obtusely lacinated leaves, lying over one another, marked on the surface with white tubercles reticularly disposed through the green substance of the leaf, shooting out underneath fine capillary roots: from the extremities of the leaves issue clear whitish pedicles, bearing globular bodies, which when ripe contain black minute seeds like dust. It is perennial, grows on

## H E P

moist stony places, and runs up to seed in March or April.

This moss is recommended as an aperient, resolvent, and purifier of the blood. From the penetrating though mild pungency and bitterishness of its taste, sinking as it were into the tongue, it promises to be a plant of no inconsiderable virtue, tho' in this country at present disregarded.

**HEPATITIS**, in medicine, an inflammation of the liver, with an imposthume of that organ. It bears a near resemblance to the pleurisy, only its symptoms are not so intense. It commonly either kills the patient or suppurates gradually, or degenerates into a schirrhus.

**HEPHÆSTIA**, in Grecian antiquity, an Athenian festival in honour of Vulcan, the chief ceremony of which was a race with torches.

**HEPTACHORD**, in the ancient poetry, signified verses that were sung or played on seven chords, that is, on seven different notes. In this sense it was applied to the lyre, when it had but seven strings.

**HEPTAGON**, in geometry, a figure consisting of seven sides and as many angles.

The word is Greek, and compounded of *επτα*, seven, and *γωνια*, an angle.

If the sides be all equal, it is called a regular heptagon.

**HEPTAGONAL NUMBERS**, are a sort of polygonal numbers, wherein the difference of the terms of the corresponding arithmetical progression is 5.

One of the properties of these numbers is, that if they be multiplied by 40, and 9 be added to the product, the sum is a square number.

**HEPTAMERIS**, in music, the seventh part of a meris, being, according to M. Sauveur, the forty-third part of the octave. See the article **OCTAVE**.

**HEPTANDRIA**, from *επτα*, seven, and *ανδρ*, male, the name of the seventh class in the Linnæan system of botany, comprehending those plants whose flowers are hermaphrodite, and furnished with seven stamina, or male parts, in each.

Of this class are the horse-chestnut, trientalis, &c.

**HEPTANGULAR**, in geometry, an appellation given to figures which have seven angles.

**HEPTARCHY**, a government consisting of seven persons, or a country divided into seven kingdoms.

The word is Greek, and formed of *επτα*, seven, and *αρχη*, rule.

The Saxon heptarchy included the southern and northern parts of England, which was cantoned into seven petty kingdoms, as those of Kent, South-Saxons, West-Saxons, East-Saxons, Northumberland, the East-Angles, and Mercia. The heptarchy was formed by degrees from the year 457, when the kingdom of Kent was first erected, and terminated

nated in 805, when king Egbert re-united them into a monarchy.

**HEPTATEUCH**, in literature, a volume consisting of seven books.

The word is Greek, and compounded of *επτα*, seven, and *τευχος*, a book or work.

Heptateuch chiefly denotes the five books of Moses, called the Pentateuch, together with the two following books, Joshua and Judges.

**HERACLEONITES**, a sect of Christians, the followers of Heracleon, who refined upon the Gnostic divinity, and maintained that the world was not the immediate production of the Son of God, but that he was only the occasional cause of its being created by the Demiurgus. The Heracleonites denied the authority of the prophecies of the Old Testament, maintaining that they were mere random sounds in the air; and that St. John the Baptist was the only true voice that directed to the Messiah.

**HERACLEUM**, cow-parsnip, in botany, a genus of umbelliferous plants, the general flower of which is difform and radiated; the single flowers of the disc consist each of five equal petals, but those of the radius consist of five unequal petals. The fruit is elliptic, compressed, and striated on each side, in the middle, and contains two oval compressed seeds.

The genus includes the sphondylium of Tournefort.

**HERACLIDÆ**, or *Return of the HERACLIDÆ into Peloponnesus*, in chronology, a famous epocha, that constitutes the beginning of profane history; all the time preceding that period being accounted fabulous.

This return happened in the year of the world 2862, an hundred years after they were expelled, and eighty after the destruction of Troy.

**HERALD**, an officer at arms, whose business it is to declare war, to proclaim peace, to marshal all the solemnities at the coronation, christening, marriage, and funeral of princes, to blazon and examine coats of arms, &c.

The three chief heralds are called King's at Arms, the principal of which is Garter; the next is called Clarencieux, and the third Norroy; these two last are called provincial heralds.

Besides these, there are six other inferior heralds, viz. York, Lancaster, Somerset, Richmond, Chester, and Windsor; to which, on the coming of king George I. to the crown, a new herald was added, styled Hanover herald; and another, styled Gloucester king at arms.

The kings at arms, the heralds, and four pursuivants, are a college or corporation, erected by a charter granted by Richard III. by which they obtained several privileges, as to be free from subsidies, tolls, and all troublesome offices.

**HERALDRY**, the art of armoury and blazon-

ing, which comprehends the knowledge of what relates to solemn cavalcades and ceremonies at coronations, instalments, the creation of peers, nuptials, funerals, &c. and also whatever relates to the bearing of arms, assigning those that belong to all persons, regulating their right and precedencies in point of honour, and restraining those who have not a just claim from bearing coats of arms that do not belong to them. See **BLAZONING**, **ARMS**, **SHIELD**, **BEARING**, &c.

**HERB**, a denomination common to all plants, whose stalks die every year, after their seed is ripe.

The word is derived from the Latin *herba*, which signifies the same thing.

There are some herbs whose root perishes with the stem, and others where the root survives the stem by several years. The former are called annuals: those which only bear flowers and fruit the second year, or even the third, and then perish, are called biannuals. Herbs whose roots do not perish after they have shed their seed, are called perennials, and, if they keep their leaves all the year round, they are called ever-greens. Herbs are also distinguished into kitchen, salad, and medicinal herbs.

**HERB-CHRISTOPHER**. See **ACTOEA**.

**HERBAGE**, in law, signifies the pasture provided by nature for the food of cattle; also the liberty to feed cattle in the forest, or in another person's ground.

**HERBAL**, in literary history, a book that treats of the classes, genera, species, and virtues of plants.

**HERBAL** is sometimes used also for what is more usually called *hortus siccus*.

**HERBALIST**, the author of an herbal, or one who is skilled in plants.

**HERBIVOROUS ANIMALS**, those which feed only on vegetables.

**HERCULES**, in astronomy, one of the constellations in the northern hemisphere. See the article **CONSTELLATION**.

**HERD**, a company of eatable cattle of the larger sort, as cows, oxen, swine, deer, &c. also of wild beasts.

**HEREDITAMENTS**, whatever immoveable things a person may have to himself and his heirs, by way of inheritance; and which, if not otherwise bequeathed, descend to him who is next heir, and not to the executor, as chattels do.

This word extends to whatever is inheritable, be it real, personal, or mixed; and in conveyances, by the grant of hereditaments, manors, houses, lands, rents, &c. will pass.

**HEREDITARY**, an appellation given to whatever belongs to a family by right of succession, from heir to heir.

**HERESY**, the crime of obstinately persisting in opinions that are contrary to the fundamentals of religion.

**HERETIC**, a general name for all such persons under

under any religion, but especially the Christian, as profess or teach religious opinions contrary to the established faith, or to what is made the standard of orthodoxy.

**HERISSON**, in fortification, a beam armed with a great number of iron spikes, with their points outwards, and supported by a pivot, on which it turns.

These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket doors of a town or fortress, to secure those passages, which must of necessity be often opened and shut.

**HERMANNIA**, in botany, a genus of plants whose flower is pentapetalous and twist against the sun; the stamina are five broad filaments, topped with erect acuminate antheræ. The fruit is a roundish pentagonal capsule, with five cells, containing a number of small seeds.

**HERMAPHRODITE**, one who partakes of both sexes.

The word is Greek, *Ερμαφροδιτος*, and compounded of *Ερμης*, Mercury, and *Αφροδιτη*, Venus, as being a mixture of Mercury and Venus, that is, of male and female.

Most, if not all those reported to be hermaphrodites, are probably no other than mere women, whose clitoris is grown to an exorbitant size, and whose labia pudendorum are become preternaturally tumid.

Among the insect class of animals, indeed, hermaphrodites are very frequent: such are worms, snails, leeches, &c.

**HERMAPHRODITE FLOWERS**, among botanists, are those which contain both the male and female organs of generation; these are by far the most numerous.

**HERMATHENA**, among antiquarians, a statue representing Mercury and Minerva both in one.

**HERMETIC**, or **HERMETICAL**, an appellation given to whatever belongs to chemistry, from Hermes Trismegistus, who is supposed to have been its inventor.

**HERMETICAL PHILOSOPHY**, that which undertakes to solve all the phenomena of nature from the three chemical principles, salt, sulphur, and mercury. A considerable addition was made to the ancient hermetical philosophy by the modern doctrine of alkali and acid. See **ALKALI**.

**HERMETICAL PHYSIC**, the art of healing, as founded on the hermetical philosophy.

**HERMETICAL SEAL**, a method of stopping glass-vessels for chemical operations so very accurately, that nothing can escape. It is done by heating the neck of the vessel in the flame of a lamp, till it be ready to melt, and then twisting it close together with a pair of pincers.

Vessels may likewise be sealed hermetically, by stopping them with a plug of glass well luted into the neck of the vessel; or by inverting another

ovum philosophicum over that wherein the matter is contained.

**HERMIT**, a devout person retired into solitude to be more at leisure for prayer and contemplation.

The word is derived from the Greek, *ερημος*, a wilderness.

**HERMODACTYL**, in pharmacy, the root of an unknown plant, brought from Turkey, of the shape of a heart flattened; of a white colour; compact and solid, yet easy to cut or powder. It is not now known in practice.

**HERNANDIA**, in botany, a genus of plants producing male and female flowers on the same plant; the corolla of the male as well as the female is divided into six segments; when the flower is decayed, the cup becomes a large inflated oblong fruit, perforated at each end, containing a hard globose nut lightly depressed.

We know only one species of this genus, which is the *hernandia*, with a large umbilicated ivy-like leaf, commonly called, in the West-Indies, Jack in a box.

**HERNIA**, in medicine, a tumor formed by the descent of the intestines or omentum out of their place: it is popularly called a rupture.

**HERNIARIA**, rupture-wort, in botany, a genus of plants whose flower is apetalous, but consists of a monophyllous-coloured cup cut into five spreading segments, and is persistent. The fruit is a small capsule placed in the bottom of the cup, and contains a smooth oval pointed seed.

A species of this genus, called *herniaria glabra* or smooth rupture-wort (which grows naturally in some parts of England) is recommended by Schroder in a diabetes: he says, it helps to dissolve the stone, and absterges the mucus from the stomach and other parts; but its chief use is in plaisters and ointments, to be applied outwardly against ruptures.

**HERO**, in the ancient mythology, a great and illustrious person, of a mortal nature, though supposed by the populace to partake of immortality; and, after his death, placed among the number of the gods.

Heroes were persons partly of divine and partly of human extraction, being begot between a deity and a mortal, and coincides with what we otherwise call a demi-god; such was Hercules, who was the son of Jupiter by Alcmena: accordingly Lucian describes a hero to be a medium between a god and man, or rather a composition of both.

**HERO** is also used in a more extensive sense for a great, illustrious, and extraordinary personage; particularly in respect of valour, courage, intrepidity, and other military virtues.

**HERO of a Poem, or Romance**, is the principal personage, or character therein. See the article **CHARACTER**.

The hero of the *Iliad* is Achilles; of the *Odyssæ*, Ulysses; of the *Æneid*, Æneas; of Tasso's *Jerusalem*,

salem, Godfrey of Bulloign; of Milton's Paradise Lost, the Messiah; though Mr. Dryden will have the Devil to be Milton's hero, in regard he gets the better of Adam, and drives him out of Paradise.

**HEROIC**, something belonging to a hero, or heroine: thus,

**HEROIC AGE**, that age or period of the world wherein the heroes are supposed to have lived. The heroic age coincides with the epic poem. See **EPIC**.

**HEROIC VERSE**, that wherein heroic poems are usually composed; or it is that proper for such poems. In the Greek and Latin, hexameter verses are usually denominated heroic verses, as being alone used by Homer, Virgil, &c. See the article **HEXAMETER**.

Alexandrine verses of twelve syllables were formerly called heroic verses; but latter writers use verses of ten syllables.

**HEROINE**, a woman of an heroic spirit, or who makes the principal personage in an heroic poem. See **HERO** and **POEM**.

**HERON**, in ornithology, a bird of the ardea-kind, with a hanging crest.

**HERPES**, in medicine, a bilious pustule, which breaking out in different manners upon the skin, accordingly receives different denominations.

If they appear single, as they frequently do in the face, the base is inflamed, and the top pointed; and having discharged a drop of matter, the redness and pain go off, and they dry away. There is another sort more corrosive and of greater malignity, when a cluster of pustules rise in a ring, accompanied with smart, and sometimes with great itching; this species is termed *serpigo*, and vulgarly the *tetter* or *ring-worm*.

Another kind of this disease appears in large clusters upon the neck, breast, loins, &c. attended with a slight fever and inflammation. The heads are white and mattery, which are succeeded by a small round scab resembling millet seed, whence its name, and vulgarly called *shingles*. See the article **ERYSIPELAS**.

**HERRING**, in ichthyology, a species of *clupea*, with the lower jaw longest, and without any black spots. It is from five to eight inches in length, and between one and two in breadth.

**HERRING Fishery**. Herrings are chiefly found in the North sea. They are a fish of passage, and commonly go in shoals, being very fond of following fire or light, and in their passage they resemble a kind of lightning. About the beginning of June, an incredible shoal of herrings, probably much larger than the land of Great-Britain and Ireland, come from the north on the surface of the sea; their approach is known by the hovering of a sea fowl in expectation of prey, and by the smoothness of the water; but where they breed, or what particular place they come from, cannot be easily discovered. As this great shoal passes between the shores of Greenland and the north cape, it is probably con-

fined, and as it reaches the extremities of Great-Britain, is necessarily divided into two parts. For we find one part of the herrings steering west, or south-west, and leaving the islands of Shetland and Orkney to the left, pass on towards Ireland, where being interrupted a second time, some keeping the shore of Britain, pass away south down St. George's channel; while the other part, edging off to the south-west, coast the western ocean, till they reach the south shore of Ireland, and then steering south-west, join the rest in St. George's channel. The other part of the first division made in the north, parting a little to the east and south-east, pass by Shetland, and then make the point of Buchan-ness, and the coast of Aberdeen, filling as they go, all the bays, firths, creeks, &c. with their innumerable multitudes. Hence they proceed forward, pass by Dunbar, and rounding the high shores of St. Abbe's Head, and Berwick, are seen again off Scarborough; and even then not diminished in bulk, till they come to Yarmouth roads, and from thence to the mouth of the Thames, after which, passing down the British Channel, they seem to be lost in the Western ocean.

There is nothing particular in the manner of fishing. The nets wherein the fish are drawn, should regularly have their meshes an inch square to let all the lesser fry go through.

**Curing and preparing HERRING**. The commerce of herring, both white or pickled, and red, is very considerable. The white Dutch herrings are the most esteemed, being distinguished into four sorts, according to their sizes; and the best are those that are fat, fleshy, firm, and white, salted the same day they are taken with good salt, and well barrelled. The British herrings are little inferior, if not equal to the Dutch; for in spite of all their endeavours to conceal the secret, their method of curing, lasting, or casking the herrings, has been discovered, and is as follows. After they have hauled in their nets, which they drag in the sterns of their vessels backwards and forwards in traversing the coast, they throw them upon the ship's deck, which is cleared of every thing for that purpose: the crew is separated into sundry divisions, and each division has a peculiar task: one part opens and guts the herrings, leaving the melts and roes; another cures and salts them, by lining or rubbing their inside with salt; the next packs them, and between each row and division they sprinkle handfuls of salt; lastly, the cooper puts the finishing hand to all, by heading the casks very tight, and stowing them in the hold. It is customary with us to wash the herrings in fresh water, and steep them twelve or fifteen hours, in a strong brine, before we proceed to barrel them.

**Red HERRINGS** must lie twenty-four hours in the brine, inasmuch as they are to take all their salt there, and when they are taken out they are spitted, that is, strung by the head on little wooden spits, and

and then hung in a chimney made for that purpose : after which, a fire of brush-wood, which yields a deal of smoke, but no flame, being made under them, they remain there till sufficiently smoked and dried, and are afterwards barrell'd up for keeping.

HERSE, in fortification, is a lattice or portcullice, made in the form of a harrow, and stuck full of iron spike.

It is usually hung by a rope, fastened to a moulinet, which is cut in case of a surprize, or when the first gate is broken with a petard, to the end that it may fall and stop up the passage of the gate, or other entrance of a fortress.

These hersees are also often laid in the roads, with the points upwards, to incommode the march both of the horse and infantry.

HERSILLON, in the military art, a sort of beam, &c. between ten and twelve feet long, whose two sides are full of spikes, to incommode both horse and foot.

The word is a diminutive of the preceding.

HESPER, *Hesperus*, in astronomy, the evening star, Venus being so called when she sets after the sun.

The word is Greek, *Εσπερος*, the brother of Atlas, and father of the Hesperides.

HESPERIDES, in the ancient mythology, were the daughters of Hesperus, which were three in number, *Ægle*, *Arethusa*, and *Hesperethusa*. They are represented by the ancients as having the keeping of certain golden apples on the other side the ocean. The poets assign them a dragon to watch the fruit : this dragon Hercules slew, and carried off the apples.

HESPERIS, dame's violet, in botany, a genus of plants, whose flower is tetrapetalous and cruciform ; the stamina are six subulated filaments (two of which are shorter than the rest) these are topped with linear erect antheræ. The fruit is a plain oblong compressed bilocular pod, with two valves, containing many ovated compressed seeds.

HETEROCLITE, among grammarians, one of the three variations in irregular nouns, and defined by Mr. Ruddiman a noun that varies in declension ; as *hoc vas, vasis* ; *hæc vasa, vasorum*.

Other grammarians take the word heteroclite in a larger sense, applying it to all irregular nouns.

HETERODOX, in polemical theology, any thing contrary to the faith and doctrines of a true church.

HETERODROMUS VECTIS, in mechanics, a lever, wherein the fulcrum, or point of suspension, is placed between the power and the weight. See the article LEVER.

HETEROGENEOUS, or HETEROGENEAL, something that consists of parts of dissimilar kinds, in opposition to homogeneous. See HOMOGENE-  
OUS.

HETEROGENEOUS, in mechanics, such bodies whose density is unequal in different parts of their bulk ; or they are such whose gravities in different parts are not proportionable to the bulks thereof : whereas bodies equally dense or solid in every part, or whose gravity is proportionable to their bulk, are said to be homogeneous.

HETEROGENEOUS LIGHT is, by Sir Isaac Newton, said to be that which consists of rays of different degrees of refrangibility : thus the common light of the sun or clouds is heterogeneous ; being a mixture of all sorts of rays.

HETEROGENEOUS NOUNS, one of the three variations in irregular nouns ; or such as are of one gender in the singular number, and of another in the plural.

HETEROGENEOUS QUANTITIES are those which are of such different kinds, as that one of them taken any number of times, never equals or excels the other.

HETEROGENEOUS SURDS are such as have different radical signs, as  $\sqrt{a a}$ ,  $\sqrt{b b}$ ,  $\sqrt{9}$ ,  $\sqrt{18}$ , &c. See SURD.

HETEROSCHII, in geography, commonly denotes those inhabitants of the earth in the temperate zones, whose shadow at noon is always projected the same way, either northward or southward.

The word is Greek, and compounded of *ετερος*, different, and *σκια*, a shadow.

Heteroscii however, strictly denotes those inhabitants which, during the whole year, have their noon-tide shadows projected different ways from each other. Thus the inhabitants of the northern temperate zone are heteroscii with regard to those of the southern. The inhabitants of one part of the torrid zone are heteroscii with regard to those of the rest, and to those of one of the temperate zones, except at the solstices ; and even at that time, all of the torrid zone are heteroscii with regard to those of the temperate zones : but as the people of the torrid zone have their shadow now on this, and then on that side, they are called amphiscii. See AMPHISCII.

HETEROUSIANS, a name composed of *ετερος* other, and *ουσια* substance ; being given to a sect of Arians, who did not believe that the Son of God was of a substance like to that of the Father, which was the opinion of another branch of the Arians, who were from thence called Homoousians ; but that he was of another substance, different from that of the Father.

HEUCHERA, in botany, a plant which produces many cordated leaves of a lucid green, and crenated on their edges ; from between these ariseth the foot stalks of the flower, about a foot high, dividing at the top into a loose panicle, sustaining many quinquepetalous flowers of a dull purple-colour, which afterwards turns each to an ovate acuminate capsule, with two reflexed horns, and two cells filled with many small seeds.

# H I B

**HEXACHORD**, in ancient music, a concord called by the moderns a sixth.

**HEXAEDRON**, *Hexaedron*, in geometry, one of the Platonic or five regular bodies, being a solid consisting of six equal sides or faces, popularly called a cube.

The square of the side of a hexaedron is in a subtriple ratio to the square of the diameter of the circumscribed sphere. Hence the side of the hexaedron is to the side of the sphere it is inscribed in, as 1 to  $\sqrt{3}$ , and consequently incommensurable thereto.

**HEXAGON**, in geometry, a figure of six sides, and as many angles.

If the sides and angles be equal, it is called a regular hexagon. The side of a regular hexagon inscribed in a circle is equal to the radius of that circle; hence a regular hexagon is inscribed in a circle, by setting the radius off six times upon the periphery: As 1 to 1.672, so is the square of the side of any regular hexagon to the area thereof nearly.

To describe a hexagon on a given line A B (plate LX, fig. 2.) draw an equilateral triangle A B C, and the vertex C will be the center of a circle, which will circumscribe the hexagon required.

**HEXAMETER**, in the Greek and Latin poetry, a verse consisting of six feet.

The first four feet of a hexameter may be either dactyls or spondees; but the last foot should in strictness be a spondee, and the last but one a dactyl, as in Homer and Virgil.

**HEXANDRIA**, from *εξ*, six, and *ανδρ*, male, the name of the sixth class in the Linnæan system of botany, including all those plants whose flowers are hermaphrodite, and furnished each with six stamina or male parts. To this class belong the lilly, narcissus, tulip, asparagus, aloe, garlic, with several other genera.

**HEXAPETALOUS FLOWERS**, among botanists, are those whose corolla consists of six petals or flower leaves.

**HEXAPLA**, in church-history, a work published by Origen, containing a part of the Old Testament in the original Hebrew, with several versions of it in six columns; from whence it was called hexapla, or the six-fold edition.

**HEXASTYLE**, in architecture, a building with six columns in front.

**HIATUS** properly signifies an opening, chasm, or gap; but it is particularly applied to those verses where one word ends with a vowel, and the following word begins with one, and thereby occasion the mouth to be more opened, and the sound to be very harsh.

**HIBISCUS**, in botany, a genus of plants whose flower consists of a double persistent calyx, containing a quinquepetalous cordated corolla. The stamina are composed of a number of filaments joined in a column, and terminated with reniform antheræ. The fruit is a quinquevalvular capsule with five cells,

# H I E

which contains several kidney-shaped seeds. — This genus includes the *malvaviscus* of Dillenius, and the *ketmia* of Tournefort, a species of which is the well known shrub commonly called *althæa frutex*.

**HICCUP**, or *Hiccough*, *Singultus*, in phycic, a spasmodic, convulsive, interrupted, and uneasy concussion of the diaphragm and some of the parts affixed to it, made in inspiration, and accompanied with a sonorous explosion of the air through the mouth.

**HIDE**, the skin of beasts, but particularly applied to those of large cattle, as bullocks, cows, horses, &c.

**HIDE of Land**, was such a quantity of land as might be plowed with one plough within the compass of a year, or so much as would maintain a family; some call it sixty, some eighty, and some an hundred acres.

**HIDE-BOUND**, among farriers, a distemper in horses when the skin sticks so fast to the back and ribs, that the hand cannot separate one from the other without great difficulty; his body is at the same time lean, his back-bones stand up, his guts are for the most part deficient in moisture, and his dung dry and more offensive than common.

If a horse become hide-bound by hard riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or some other disease, if that be cured which is the cause, the effect will cease; but if he has no fever upon him, and he is hide-bound only from lowness of blood and spirits, give him boiled barley, white-water, or the like, and when his flesh is raised, harden it with good oats, beans, and moderate exercise.

**HIERACIUM**, hawkweed, in botany, a genus of plants, whose flower is compound, uniform, and imbricated; the corollulæ are monopetalous, linear, legulated, and indented in five parts; at the extremity of the stamina are five very short hairy filaments topped with cylindraceous antheræ; a pericarpium is wanting, but the cup, which is ovated and connivent, contains the seeds, which are solitary, four-cornered, short, and winged with down.

**HIERACITES**, *Hieracite*, in church-history, Christian heretics in the third century, so called from their leader Hierax, a philosopher of Egypt; who taught that Melchisedec was the Holy Ghost, denied the resurrection, and condemned marriage: he likewise held, that no one could be saved who died before he arrived at years of discretion. The disciples of Hierax taught that the Word, or Son of God, was contained in the Father, as a little vessel is contained in a great one; from whence they had the name Metangimonists, from the Greek word *μεταγγιμονος*, which signifies contained in a vessel.

**HIERARCHY**, among divines, denotes the subordination of angels. See the article **ANGEL**.

**HIERARCHY** likewise denotes the subordination of the clergy, ecclesiastical polity, or the constitution

# H I L

tion and government of the Christian church, considered as a society.

**HIEROGLYPHICS**, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writing as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments.

**HIGH**, *Altus*, a term of relation, importing one thing's being superior or above another: thus we say, a high mountain, the high court of parliament, high relieve, &c.

**HIGH**, in music, is sometimes used in the same sense with loud, and sometimes in the same sense with acute.

**HIGH-WATER**, the state of the tide when highest, or the time just before it begins to ebb. See the article **TIDE**.

**HIGH-WAY**, a free passage for the king's subjects, on which account it is called the king's highway; though the freehold of the soil belong to the lord of the manor, or the owner of the land.

**HIGHNESS**, a title given to princes. Before king James I. the kings of England had no other title but that of highness; which was also the case of the kings of Spain before Charles V.

At present all the sons of crowned heads are stiled royal highness, as the electors of Germany are electoral highness.

**HILARY-TERM**, among lawyers. See **TERM**.

**HILL**, in the natural history of the earth. See **MOUNTAIN**.

Hills are of great use in a garden, as,

1. They serve as screens to keep off the cold and nipping blasts of the northern and eastern winds.

2. The long ridges and chains of lofty mountains, being generally found to run from east to west, serve to stop the evagation of those vapours towards the poles, without which they would all run from the hot countries, and leave them destitute of rain.

3. They condense those vapours, like alembic heads, into clouds; and so, by a kind of external distillation, give origin to springs and rivers; and, by amassing, cooling, and condensing them, turn them into rain, and by that means render the fervid regions of the torrid zone habitable.

4. They serve for the production of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experiment and calculation, that hills, though they measure twice as much as the plain ground they stand upon, yet the produce of the one can be no more than the other; and therefore, in purchasing land, the hills ought not to be bought for more than their superficial measure, i. e. to pay no more for two acres upon the side of an hill, than for one upon the plain, if the soil be equally rich.

It is true, that those lands that are hilly and mountainous, are very different, as to their valuable con-

# H I P

tents, from what are found in flat and plain ground, whether they be planted, sown, or built upon; as for example:

Suppose an hill contains four equal sides, which meet in a point at the top; yet the contents of these four sides can produce no more grain, or bear no more trees, than the plain ground on which the hill stands, or than the base of it; and yet by the measure of the sides there may be double the number of acres, rods, and poles, which they measure on the base or ground-plot.

For as long as all plants preserve their upright method of growing, hilly ground can bear no more plants in number than the plain at the base.

Again, as to building on an hill, the two sides of an hill will bear no more than the same number of houses than can stand in the line at the base.

And as to rails, or park-pailing over an hill, though the measure be near double over the hill to the line at the bottom, yet both may be inclosed by the same number of pales of the same breadth. *Miller's Gard. Dict.*

**HIN**, a Hebrew measure of capacity for things liquid, containing the sixth part of an epha, or one gallon two pints, or two thousand, five hundred and thirty-three solid inches, English measure.

**HINE**, a female stag in the third year of its age.

**HIND CALF**, a male hart, or hind, in the first year. She fawns in April or May.

**HIND**, or **HINE**, a husbandman's servant. Thus a person who oversees the rest, is called the master-hine.

**HINGES**, in building, those iron-joints, whereby doors, tables, &c. open, shut, or fold, &c. Of these there are various species.

**HIP**, dog-rose, a species of wild briar, with single pentapetalous flowers, of a whitish colour, mixed with various shades of red. It is one of the largest plants of the rose kind; grows wild in hedges; and flowers, as the garden sorts, in June.

The fruit, the only part of the dog-rose made use of in medicine among us, is agreeably dulco-acid, and stands recommended as a cooling restraining, in bilious fluxes, sharpness of urine, and hot indispositions of the stomach: the fresh pulp is made in the shops into a conserve, by mixing three ounces of it with five of fine sugar. The pulp should be separated with great care from the rough prickly matter which incloses the seeds; a small quantity of which, retained in the conserve, is apt to occasion an uneasiness at the stomach, pruritus about the anus, and sometimes vomiting.

**HIP-GOUT**, *Sciatica*. See the articles **GOUT** and **SCIATICA**.

**HIP-MOULD** is by some used for the back of the hip, but others understand it to mean the prototype or pattern, commonly made of a thin piece of wainscot, by which the back and sides of the hip are set out.

# H I P

**HIP-ROOF**, among carpenters, called also Italian roof, is a roof which has neither gable-head, thread-head, nor jerken-head, by which is meant such heads as are both gable and hip at the same end; for it is a gable or upright as high as the collar-beam, and then there are two short hips, which shut up with their tops to the tops of a pair of rafters, which country carpenters call singlars. A hip-roof has rafters as long, and with the angles of the foot, &c. at the ends of the buildings, as it has at the sides; and the feet of the rafters at the ends of such buildings as have hip-roofs, stand on the same plane, viz. parallel with the horizon, and at the same height from the foundation, with rafters on the sides of the roof.

**HIPPOCAMPUS**, the sea-horse, in ichthyology, the square-bodied syngnathus, with no fin at the tail. It is five inches long, and where thickest, about an inch in diameter; the head is long, slender, and compressed, forming a kind of snout; the body is of a quadrangular figure, but the divisions are not equal, and in the thickest part it is hexangular or heptangular.

It is a very singular and rare fish; the tail of which usually curls up in the drying, and its head being bent down, gives it a rude resemblance to a horse; whence the name.

**HIPPOCASTANUM**, horse-chestnut, in botany. See **HORSE-CHESTNUT**.

**HIPPOCENTAUR**, in antiquity, a fabulous animal, half man half horse.

What gave rise to the fable of hippocentaurs, was this. The Thessalians are said to have been the first inventors of the art of breaking horses; and being first seen on horseback, they seemed to make but one body with the horses; whence the origin of the fable.

**HIPPOCRAS**, an infusion of aromatic powders in wine, which is afterwardsedulcorated with sugar and honey; being so called because that, when the infusion is finished, it is strained through Hippocrates's sleeve.

It is prepared of various aromatics and other ingredients, according to the different intentions to be answered.

**HIPPOCRATES'S SLEEVE**, a kind of filtre or straining bag formed by joining the opposite angles of a square piece of flannel in form of a pyramid, and used to strain syrups, decoctions, &c. for clarification.

**HIPPOCREPIS**, horse-shoe vetch, in botany, a genus of plants producing papilionaceous flowers; the vexillum of each is cordated with a narrow base the length of the cup, the carina is lunulated and compressed, and the alæ are oval, oblong, and blunt. The fruit is a compressed pod, very long reflexed, and jointed like a horse-shoe; the seed is single in each joint, of an oblong and incurved figure.

**HIPPODROME**, in antiquity, the course where horse-races were performed.

# H I S

**HIPPOMANES**, the manchineel tree, in botany. See **MANCHINEEL**.

**HIPPOPHÆ**, sea-buckthorn, in botany, a genus producing male and female flowers on different plants; having no corolla, the cup of the male flower is divided into two parts, as is also the calyx of the female. The fruit is a globose unilocular berry, inclosing a roundish seed.

**HIPPOPOTAMUS**, the river horse, a genus of quadrupeds, of the order of the jumenta, the characters of which are these: the fore-teeth of the upper jaw are four, and placed in pairs; those of the lower jaw are prominent, and the intermediate ones are protended forward: the canine teeth are single, and obliquely truncated; the teats are only two, and placed near the groin.

The hippopotamus is a native of Africa, passing a great part of its time under water, in the rivers of the Nile and Niger; but comes on shore to sleep and breed. It is a large unwieldy animal, as big as an ox.

**HIPPURIS**, in botany, a genus of plants, whose flower has neither calyx, corolla, or perianthium, but consists of a single filament, placed in a receptacle, and topped with semibifid antheræ. The pistillum is composed of an oblong germen with an awl-shaped stile, terminated with an acute stigma, which afterwards becomes a single roundish naked seed.

**HIRCUS**, in anatomy, a part of the auricle or outer ear, being that eminence next the temples. See the article **EAR**.

**HIRCUS**, a goat, in astronomy, a star of the first magnitude, the same with capella. See **CAPELLA**.

**HIRTELLA**, in botany, a genus of plants whose flower consists of five roundish concave petals, with a monophyllous cup divided into five parts: the fruit is an oval berry, a little compressed, broadest at top, and obtusely trigonal, containing a large seed of the same figure.

**HIRUDO**, the leech, in zoology, a well known naked insect, with a flattened but not jointed body, and broader at the end than elsewhere, and the skin soft and glossy.

**HISPID LEAF**, among botanists, one whose surface is covered with more thick and rigid hairs than the pilose leaves are.

**HISPID STALK**, among botanists, a stalk roughly hairy.

**HISSING LETTERS**, among grammarians, are S, X, and Z, so called on account of their harsh sound.

**HISTORICAL**, something that relates to history: thus we say, historical truth, historical style, historical narration of facts, &c. See the article **HISTORY**.

**HISTORIOGRAPHER**, a professed historian, or writer of history.

**HISTORY**, an account, properly speaking, of past

past transactions, narrated with such important circumstances as are proper to be transmitted to posterity, and that in a regular continued series.

History is, of all others, the most difficult province. In other subjects there is a greater latitude for the writer's imagination; but, in history, he is confined to the occurrences he relates; and these, as they are not alike entertaining, require force and judgment in the narration to make them all agreeable. The richest fields of history are scenes of action and commotion, where nations are agitated by wars abroad, or factions at home. The most delicate part of an historian, which requires the deepest penetration, and soundest judgment, are the councils of states and princes, the springs of action, the characters of men, the interest of parties, their different views, &c. History will not admit those decorations other subjects are capable of: the passions are not to be moved with any thing but the truth of the narration. All the force and beauty must lie in the order and expression. To relate every event with perspicuity, in such words as best express the nature of the subject, is the chief commendation of an historian's style. The colours facts are painted in, the strength and significancy of the several actions, the regular confusion of a battle, the distractions of a tumult, so sensibly depicted, that in reading we seem to see them; this is the art and perfection of an historical style. An historian must not only write impartially, but nobly. He that speaks to the whole world, and to all ages, that is the instructor of mankind, that pronounces the destiny of so many great men, and fixes their character with posterity, what strength of genius can be sufficient for so important an enterprize? He must be capable of forming great and noble conceptions of things, and giving such an exalted turn to his narration, as may truly comport with the dignity of his subject.

**HISTORY**, in painting, denotes a picture composed of divers figures, or persons, representing some transaction, either real or feigned. See **PAINTING**.

*Natural History.* See **NATURAL**.

**HISTRIO**, in the ancient drama, signified an actor or comedian, but more especially a pantomime, who exhibited his part by gestures and dancing.

**HITCH**, among sailors, a certain knot or noose cast upon a rope to fasten it to a post, ship, wharf, &c.

**HITHE**, or **HYTHE**, in old writers, denotes a port, wharf, or small haven, to embark, or land wares at; as *Queenhithe*, &c.

**HIVE**, *Alveare*, in country affairs, a convenient receptacle for bees. See **BEE**.

**HOACHE**, in natural history, a kind of earth approaching to the nature of chalk, but harder, and feeling like soap; whence some think that it is either the same with our sope-rock of Cornwall, or very like it. The Chinese dissolve it in water, till

the liquor is of the consistence of cream, and then varnish their china-ware with it.

**HOARSENESS**, *Rauco*, a preternatural roughness of the voice. The part affected is the aspera arteria, particularly the larynx. This is a sort of catarrhus indisposition arising from a too great acrimony, thinness, or saltiness of the lymph. *Spermaceti*, decoct. rapar. and rob. passular. are approved remedies in this disorder.

**HOASE**, among sailors, a piece of canvas sewed together at the sides, and made into the form of a tube, to convey water from one place to another; this is more particularly used in the hold or lower-apartments of the ship to fill the casks which are already securely stowed.

**HOD**, a well known instrument used by labourers to carry bricks, mortar, &c. in, at the building, or repairing of houses, &c.

**HOE**, in country affairs, a tool made like a cooper's adz, to cut up weeds in gardens, fields, &c. This tool is commonly called the hand-hoe: for other sorts of hoes see the next article.

This instrument is of great use, and should be more employed in hacking and clearing the several corners, cracks, and patches of land, in spare times of the year, which would be of no small advantage thereto.

**HOING**, according to Tull, is the breaking or dividing the soil by tillage, while the corn, or other plants, are growing thereon. It differs from common tillage, which is always performed before the corn or plants are sown or planted, or in the time of performing it: and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments. Land which, before the tillage, would have yielded little, though the more it is tilled before sowing, the more plenty of corn it yields, yet, if tilled only before the sowing, will always have some weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reason for an after tillage, such as that by hoeing. But there is another consideration that yet more requires it; this is, that as soon as the ploughman has done his business, by ploughing and hoeing the land, after sowing, the soil, of its own accord, begins to undo it all again, by tending towards its original texture and specific gravity again; the altering of which was the only business of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles, or new superficies, is the great business of the plough and harrow; but, as soon as their use is over, the earth begins to coalesce again into its former form, the particles unite together, and the artificial pores in a great measure close up. The seed is nourished in a worse ground than it was first put into, and the more the plant grows up, and requires a larger supply of food, the worse the pasture

sture becomes. While nourishment is thus denied the growing plants, they are at the same time choaked with weeds, which, being of a hardier nature than they, will grow with less supplies, and therefore thrive more vigorously, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in some degree, with the use of tillage and dung to crops of useful plants; but they have so ill managed the time of giving these assistances to nature, that there is no doubt but one third part of the nourishment raised by dung and tillage, if it were given to plants and corn at many proper seasons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of sowing.

Nature, by what she does in the animal economy, seems to point out to us something like the remedying this by hoeing; for when the teeth, as the plough, have tilled that soil or mass which is earth-altered; and when the saliva and the juices of the stomach have served to divide and attenuate it, as the salts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhausted by the numerous mouths of the lacteals, situate in the intestines. This last operation of these juices seems analogous to the meliorating the soil by hoeing, after the plants are grown, and are becoming fit for use.

Transplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by transplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be used to them with advantage, to their utmost standing, and make them vigorous all the while.

The roots of a plant are all necessarily broken off in transplanting, and it requires some time for it to strike a whole set of new ones; and if the earth about it is not kept thoroughly moistened all this time, the new formed roots will not be able to shoot, and the plant will starve in the midst of plenty: but, on the contrary, in hoeing, the same advantage of a new pasture for the plant is obtained, by the breaking the particles of the earth, and at the same time no more of the roots are broken off than can easily be supplied, and the rest remaining in their places, the plant continues growing without that stop or decay, which must happen on transplanting, and which it recovers only by degrees. It is observed, that some plants are the worse for transplanting: lucerne and saintfoin are never so good after transplanting, as when they are left in their native places, at the same distances; and finochia,

removed, is never so good and tender as when it is not. This last plant receives such a check from transplanting in its infancy, that it has afterwards a disease like the rickets, which causes knots and swellings in it, that spoil it as a delicacy. All the tap-rooted plants suffer by transplanting; for it is necessary in this to cut off the long-main root, which afterwards, however good the soil may be, never arrives at the length it otherwise would have had, and which was necessary for the success of the plant.

One great benefit of hoeing is, that it keeps plants moist in dry weather, the advantage of which to their growth is easily seen. This good office it performs on a double account. First, as they are better nourished by hoeing, they require less moisture, and consequently carry off less; for those plants which receive the greatest increase, having most terrestrial nourishment, carry off the least water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats, being sown on a piece of ground well divided by tillage and dung, will come up and grow well without rains, when the same grains sown on another part of the same land, not thus dunged or tilled, will scarce come up at all without rains, or if they do, will wait wholly for the rains for their growth and increase.

The hoe also, particularly the horse-hoe, for the other does not go deep enough, procures moisture for the roots from the dews which fall most in dry weather; and these dews seem to be the most enriching of all moisture, as it contains in it a fine black earth, which will subside from it in standing, and which seems fine enough to be the proper pabulum, or food for plants.

A demonstration, that the tilled earth receives an advantage from these dews, which the untilled does not, is this; dig a hole in any piece of land, of such a depth as the plough usually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moist, while all the rest of the ground, at the same depth, is dry. Or, if a field be tilled in lands, and one land be made fine by frequent deep ploughings, while another is left rough by insufficient tillage, and the whole field be then ploughed a-crofs in dry weather, which has continued long, every fine land will be turned up moist, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly soaked with rain, will continue wet longer than fine tilled land adjoining to it, yet, this water serves rather to chill than to nourish the plants standing in it, and to keep out the other benefits of the atmosphere; it leaves the ground much harder also than before, when it is finally exhaled out of it; and when, at length, the earth is then hardened, it can receive

no benefit from any thing less than a deluge of rain, which seldom falls till the season of vegetation is over.

As fine hoed ground is not so long soaked with rain, so the fine dews never suffer it to become perfectly dry. This appears from the flourishing state of plants in hoed ground, while others near them, but in ground not hoed, are starved for want of nourishment. The common opinion is against this, but observation proves it to be true against the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather for fear of letting in the drought, as they call it; whereas hoeing this is the only method of keeping away the drought, and without either this, or watering, they must perish in these seasons. *Tull's Horse-Hoeing Husbandry.*

**HOG**, *sus*, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which are these: the upper fore-teeth are four in number, and are convergent; those of the lower-jaw are eight, and are patulous: the canine teeth of the upper jaw are two, and very short; those of the under jaw are single, and exerted: the crown of the head is carinated, and the hoof is divided. See the article **SWINE**.

Besides the common hog, there are several other species, as, 1. the American hog, with the back bristly behind, and with a naked tail: 2. the musk-hog, with a cyst, or gland on the back, in which is secreted a perfumed fluid; its tail is naked: 3. the babyroussa, with two teeth growing on the forehead.

**HOGSHEAD**, in commerce, a measure of capacity, containing sixty-three gallons.

**HOISING**, in the sea-language, the act of drawing up any weighty body by the help of a tackle or complication of pulleys.

**HOKE-DAY**, the Tuesday after Easter-week; which was the day on which the English conquered and expelled the Danes: this was, therefore, kept as a day of rejoicing, and a duty, called Hoke-Tuesday-Money, was paid to the landlord, for giving his tenants and bondmen leave to celebrate it.

**HOLCUS**, Indian millet, in botany, a genus of plants, whose flowers are male and hermaphrodite on the same plant: the corolla of the hermaphrodite flower is a bivalvular glume, with three capillary stamina and two styles, and contains an oval seed involved in the corolla; the male flower is destitute of a corolla, the cup being a glume, containing three hairy filaments topped with oblong antheræ.

**HOLD**, in ship-building, all that part of a ship's inside which reaches from end to end, from the lower deck to the floor or bottom; and contains the cargo, provisions, &c.

**HOLDFAST**, a large piece of iron, in the shape of the letter S, fixed in a wall to strengthen it: also

a tool used by joiners, carvers, &c. which goes thro' their benches, to hold fast such work as cannot be finished by its being held in the hand.

**HOLIBUT**, the name of a very large flat fish, resembling the flounder, but longer in proportion to its breadth.

**HOLLAND**, in commerce, a fine and close kind of linen, so called from its first being manufactured in Holland. See the article **LINEN**.

**HOLLOW**, in architecture, a concave moulding, about a quarter of a circle, called by some a casement, and by others an abacus.

**HOLLOW-SQUARE**, in the military art, a body of foot drawn up, with an empty space in the middle for colours, drums, and baggage.

**HOLLOW-TOWER**, according to Hanis, is a rounding made of the remainder of two brisures, to join the curtain to the orillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

**HOLLY**, *Ilex*, in botany, a well known evergreen, formerly very much planted in gardens as an ornament; it grows naturally in woods and forests in many parts of England, rising to twenty or thirty feet in height; the stem by age becomes large, and is covered with a greyish bark; the leaves, which are armed with thorns, are placed alternately on every side of the branches: the flowers are of a dirty white, and appear in May; these are succeeded by roundish berries, which turn red in autumn, and continue on the trees till after Christmas.

This tree is raised by sowing the berries in the spring, but they will not come up till the year following. There are several varieties of variegated hollies, which are increased by grafting or inoculating them on the common sort. The holly makes an excellent fence, and for that purpose is preferable to most other plants; but its being a slow grower at first, deters several from using it; but when it does take to growing, it makes amends by its height, strength, and thickness.

From the bark of the common holly is made the bird-lime, and the wood is made into hones for setting razors; it is the whitest of all hard-woods, and therefore used by inlayers; it is also used by millwrights, turners, &c.

**Knee-HOLLY**, a name given to butchers-broom. See the article **RUSCUS**.

**Sea-HOLLY**. See **ERYNGIUM**.

**HOLLYHOCK**. See **ALCEA**.

**HOLOCAUST**, a burnt-offering, or sacrifice, wholly consumed by fire; of this kind was the daily sacrifice in the Jewish church. This was done by way of acknowledgement, that the person offering, and all that belonged to him, were the effects of the Divine bounty. The heathens, who also offered holocausts, probably considered them in the same light: and the disposing of sacrifices this way was the

the general custom, till Prometheus introduced the custom of burning only a part, and retaining the remainder for his own table.

**HOLOGRAPH**, in the civil law, an instrument entirely in the hand-writing of the person who signs it.

**HOLOMETER**, a mathematical instrument for taking all sorts of measures, both on the earth and in the heavens; it is the same with the pantometer.

**HOLOSTEUM**, in botany, a genus of plants, whose flower consists of five bipartite, obtuse, equal petals, with three stamina: the fruit is an unilocular, ovate capsule, containing a number of roundish seeds.

**HOLY-GHOST**, one of the persons of the holy Trinity.

*Order of the HOLY-GHOST*, the principal military order in France, instituted by Henry III. in 1569. It consists of an hundred knights, who are to make proof of their nobility for three descents. The king is the grand master, or sovereign, and as such, takes an oath on his coronation-day, to maintain the dignity of the order.

**HOLY-THURSDAY**, the same with ascension-day. See **ASCENSION**.

**HOLY-DAYS**, the same with festivals. See the article **FESTIVAL**.

**HOLY-ROOD-DAY**, a festival otherwise called the exaltation of the cross.

**HOLY-THISTLE**, in botany. See the articles **CNICUS** and **CARDUUS-BENEDICTUS**.

**HOMAGE**, in law, is the submission, loyalty, and service which a tenant promised to his lord, when he was first admitted to the land which he held of the lord in fee: also that owing to a king, or to any superior.

**HOMAGE-JURY**, a jury in a court baron, consisting of tenants that do homage to the lord of the fee.

This jury makes enquiry into, and presentments of, defaults and deaths of tenants, and of admittances and surrenders into the lord's court.

**HOMESOKEN**, a privilege enjoyed by every person in his own house or home, which ought not to be invaded.

**HOMICIDE**, in common law, the killing a man.

It is divided into voluntary and casual. Casual is either merely casual, or mixed; the former is when a person kills another by pure mischance, being about his lawful occasions: it is accounted mixed, when there is negligence or some unwarrantable circumstance attending the action. Voluntary homicide, that which is deliberate; and is either with a precedent malice, or without: the former is a felonious killing, with malice prepense, any person in the realm, who is under his majesty's protection.

**HOMILY**, in ecclesiastical writers, a sermon, or discourse, upon some point of religion, delivered in

a plain manner, so as to be easily understood by the common people.

**HOMODROMUS VECTIS**, that kind of lever, in which the weight is in the middle, between the power and the fulcrum, or the power in the middle between the weight and the fulcrum. See **LEVER**.

**HOMOGENEUS**, or **HOMOGENEAL**, denotes such subjects as consist of parts of the same nature, in contradistinction to heterogeneous, where the parts are of different natures.

**HOMOGENEAL LIGHT**, that whose rays are all of the same colour, degree of refrangibility, and reflexivity. See **COLOUR**.

**HOMOGENEAL NUMBERS**, such as are of the same kind.

**HOMOGENEAL SURDS**, such as have one common radical sign, as  $\sqrt[2]{a} \sqrt[2]{b}$ , or  $\sqrt[3]{b^3}$ . See the article **SURDS**.

**HOMOGENEUM COMPARATIONIS**, in algebra, the known quantity in an equation, the same with absolute number. It is so called to distinguish it from the other terms, which, though homogeneous, are not the quantities to which things are here referred.

**HOMOLOGOUS**, in geometry, is applied to the correspondent sides and angles of similar and equiangular figures, which are said to be homologous, or in proportion to one another.

**HOMOLOGOUS THINGS**, in logic, those which agree in name, but are of different natures.

**HOMONYMOUS**, an appellation given to words which have two different significations, being the same with equivocal terms.

**HONE**, a fine kind of whetstone, used for setting razors, pen-knives, and the like.

**HONEY**, *Mel*, a sweet vegetable juice, collected by the bee from the flowers of different plants, and deposited in the cells of the combs; from which it is extracted, either by spontaneous percolation through a sieve in a warm place, or by expression. That which runs spontaneously is purer than the expressed; a quantity of the waxy and other impurities being forced out along with it by the pressure, especially when the combs are previously heated. The best sort of honey is of a thick consistence, a whitish colour, an agreeable smell, and very pleasant taste: both the colour and flavour are said to differ in some degree according to the plants which the bees collect it from.

Honey exposed to a gentle heat, as that of a warm bath, becomes thin, and throws up to the surface its waxy impurities, together with the meal or flower, sometimes fraudulently mingled with it, which may thus be separated by disputation, so as to leave the honey pure. On continuing the heat, there rises a considerable quantity of aqueous fluid, impregnated with the fine smell of the honey: the inspissated residuum, like the honey at first, dissolves.

solves both in water and in rectified spirit, and promotes the union of oily and resinous substances with watery liquors. By treating the inspissated mass with moist clay, as practised by the sugar-bakers for purifying sugar from its unctuous treacly matter, the unctuous parts of honey may in like manner be separated, and its pure sweet matter obtained in the form of a solid, saline, white concrete.

This juice is an useful sweet, for medicinal as well as for domestic purposes; more aperient and detergent than the simpler sweet prepared from the sugar cane; particular servicable for promoting expectoration in disorders of the breast, and as an ingredient in cooling and detergent gargarisms. For these, and other similar intentions, it is sometimes mixed with vinegar, in the proportion of about two pounds to a pint, and the mixture boiled down to the consistence of a syrup; sometimes impregnated with the virtues of different vegetables, by boiling in like manner with their juices or infusions, till the watery parts of the juice or infusion have exhaled and left the active matter incorporated with the honey. The boiling of honey, though it dissipates great part of its odorous matter, and thus proves in some cases injurious to it, is in some cases also of advantage: there are particular constitutions, with which honey remarkably disagrees, and in which even very small quantities occasion gripes, purging, and great disorder: by boiling, it loses of that quality by which it produces these effects.

**HONEY-COMB**, a waxen structure full of cells, framed by the bees to deposit their honey, eggs, &c.

There is something very wonderful in the construction of the cells in the honey-comb. Each cell consists of six plane sides, which are all trapeziums, but equal to each other. The bottom of the cell is contrived with three rhombus's, HKDI, DEFL, and FIGH (pl. LX. fig. 3.) so disposed as to constitute a solid angle at I, under the three equal angles DIH, DIF, and HIF; each of which is double the maximum angle of  $54^{\circ} 44' = DIK = DKL$ . Hence it comes to pass, that a less quantity of surface is sufficient to contain a given quantity of honey, than if the bottom had been flat, in the proportion of 4658 to 5550, as has been found by calculation; that is, nearly  $\frac{1}{5}$  of the whole, so far as the figure of the ends of the cells extend in each, which fifth part of wax and labour saved, amounts to a vast deal in the whole comb. And if these admirable insects knew their advantage, they could not more nicely observe the rules of the modern geometry. Hence we may observe, that though the method of discovering the maxima and minima of quantities by fluxions is a part of knowledge which the mathematicians have but lately acquired, and which they esteem the sublimity of human science, yet this very thing was imparted to these insects at the first creation of things.

The celerity with which a swarm of bees received into a hive, where they find themselves lodged to their minds, bring their works of the combs to perfection, is amazing. There are vast numbers at work all at once; and that they may not incommode one another, they do not work upon the first comb till it is finished, but when the foundation of that is laid, they go to work upon another, so that there are often the beginnings of three or four stories made at once, and so many swarms allotted to the carrying on the work of each.

**HONEY-COMB**, in gunnery, a flaw in the metal of a piece of ordnance, when it is ill cast and spongy.

**HONOUR-POINT**, in heraldry, is that next above the center of the escutcheon, dividing the upper part into two equal portions. See the article **POINT**.

**HONEYSUCKLE**. See **LONICERA**.

*French HONEYSUCKLE*. See **HEDYSARUM**.

**HONEYWORT**. See **CERINTHE**.

**HOOD**, in falconry, a piece of leather, with which the head of a hawk, falcon, &c. is covered.

**HOOF**, *Ungula*, the horny substance that covers the feet of divers animals, as oxen, horses, sheep, &c.

A horse's hoof should be of a round, not longish figure; and its substance solid, tough, high, smooth, without any circles, somewhat shining, and of a dark colour; for that which is white is commonly brittle; in short, it ought to be of the colour of the hoof of a deer, and the whole foot round, but a little larger below than above; upright, and somewhat hollow on the inside, and so disposed that he may tread more on the toe than the heel.

The hoof of a horse is either perfect or imperfect: an imperfect hoof is one that wants any of the above qualities; and, 1. May be broad and spreading out at the sides and quarters; such a horse has, for the most part narrow heels, and will soon be flat-hoofed; he will neither carry a shoe long, nor travel far. 2. Others are rugged or brittle-hoofed, which is a sign that it is too hot and dry. 3. Some are long, which causes the horse to tread all upon his heels, and by that means to breed wind-galls. 4. There are some crooked hoofs, broad on the outsides and narrow within, by which means the horse is splay-footed. 5. Others have flat hoofs, and not hollow within, which give rise to the inconveniences above specified in the first sort of imperfect hoofs; but if it be too hollow, it will dry too fast, and make him hoof bound. 6. When the frush is broad, the heels will be weak and soft, and the horse will never tread boldly on the ground. 7. Some have narrow heels; these are the tenderest of all, and the horse will grow hoof-bound.

**Bony Hoof** is the round bony swelling, growing on

on the very top of a horse's hoof, which is always caused by some blow or bruise.

The method of cure is, first to digest the swelling, either with rotten litter, or hay boiled in stale urine, or with a plaster of stale wine lees and wheat flower boiled together, in order to ripen it, and bring it to suppuration, or to dissolve the tumor. If it come to a head, lance it in the lowest part of the softness, with a thin hot iron, to let out the matter; then tent it with turpentine, deer's suet, and wax, equal quantities of which should be boiled together; and laying a plaster of the same salve over it, to keep in the tent till it be thoroughly well.

**HOOF-BOUND**, this disorder is a shrinking of the hoof at the top and at the heel, which makes the skin stare above the hoof, and grow over it.

This disorder may happen to a horse, either by keeping him too dry in the stable, by straight shoeing, or by some unnatural heat after foundering.

**HOOF-BRITTLE**, an infirmity in horses, proceeding either naturally, from the fire or dam; or accidentally, from a surfeit falling down into the feet; or from the horse's being formerly foundered.

For the cure, take unwrought wax, turpentine, sheep's suet, and hog's grease, of each four ounces; fallad oil, a quarter of a pint; and of dog's grease, half a pound: boil them all together, and with this mixture, anoint the hoof well for two or three days, especially at the setting on of the hair, and stop them with cow-dung and dog's grease, melted together.

**HOOF-SWELLED**, a disorder that sometimes happens by a prick, or a young horse's being over-riden, or too hard wrought, and which, if not speedily removed, will beget a wet spaven.

For the cure, take the strongest aqua-fortis you can get, and first file or draw away the old hoof somewhat near, with a file or drawing-iron; then touch what is left of the hoof, three or four dressings or more, with the aqua-fortis; and anoint the foot with an ointment made of one pound of hog's grease; patch-grease, three quarters of a pound; Venice-turpentine, five ounces; new wax, three ounces; and fallad oil three ounces; all melted together over the fire; and by anointing the coffin of the foot quite up to the top, you will cause a new hoof to grow upon it.

**HOOK-PINS** are bolts made with a shoulder at one end, and used by carpenters in framing: these are drove through the mortices and tenants of the work, prepared for building or wharfing.

**HOP**, *Lupulus*, or *humulus*, in botany, a plant of the dioecia pentandria class; neither the male nor female flower of which has any corolla; the cup of the male flower is composed of five leaves, that of the female is an acute quadrifid involucre,

large and of an oval figure; the seed is single, roundish, covered with a coat, and contained in the base of the cup.—It hath a creeping root, with such weak stalks that they could not support themselves without twisting about whatever is near them; they are exceeding long, rough, angular, hairy, and hollow, and the leaves proceed from the stalks by pairs, and are placed opposite; they are generally divided into three, and sometimes into five segments, and are serrated on their edges; the leaves are not in use, but the flowers is a well-known ingredient in beer and other malt liquors.

For the cultivation of hops, a rich, deep, mellow, dry soil, more inclining to sand than clay, is in general the best; and in particular, a black garden mould is excellent. Stiff clays, spewy lands, such as are apt to be overflowed by floods, hard gravels, stony grounds, very sandy ones, and such as are not at least a foot and an half deep, are altogether improper for hops.

The best situation for hop-grounds is such as inclines to the south, or lies open to it, so that they may have the benefit of the sun during the greatest part of the day. It must also be open, for the air to have a free passage and circulation between the plants; and it should be so sheltered to the east, north, and west, that neither the frosty winds in the spring may cut off the young sprouts, nor the more stormy ones in summer and autumn destroy the full-grown hops.

The ground and situation being chosen, the next business is to prepare it for the planting. In many parts of England, when the ground is broken up for this purpose, the plough goes first, and men follow it with the spades, with which they dig one spit deep in the furrows where the plough has passed, throw up the earth thus dug, and so continue to plough and dig till the whole is done. Either this tillage, if it be well performed, or the deep ploughings, cross-ploughings, and harrowings, by which careful husbandmen prepare their land for corn, will fit this for being sown with turnip-seeds in the end of July, or beginning of August, and if the turnips are hoed twice, so as to be left about eight inches asunder, they will yield a good crop, the weeds will be destroyed, and the ground will be rendered loose and fine. Another good ploughing after the turnips are taken off, will, with the ensuing winter mellowing, render it fit for being planted with hops in the spring.

The best time to begin the ploughing is in October, in order that the soil may be properly prepared to receive the benefits of the winter's frosts, rains, and snows; after which, in the beginning of spring, it should be well and deeply ploughed again, and well harrowed; and after another ploughing in March, which will be of very great service, it should be harrowed fine, and laid as even as can be.

When the ground is in proper readiness for planting, stretch along a straight side of the field, at fifteen or twenty feet distance from the hedge, and parallel to it, a line with knots or rags tied in it, as far asunder as you design your hills to be, and stick in the ground a sharp pointed stick at every knot, as marks for the places where the hills are to be made: continue the line in this manner the whole length of the ground, and from this first row you may mark out the rest of the field, either in squares, chequer-wise, at the intended distance of the hills, or in the quincunx form, where the hills of every row lie opposite to the middle of the first, in a triangular form.

The distance of the hills should be, in some measure, regulated by the nature and goodness of the soil: but, in every case, they should be far enough asunder to admit the hoe-plough at all times without danger to the plants. If the soil be dry and shallow, six or seven feet will be a convenient distance: but if it be rich, moist, and apt to bear large hops and leaves, it may be right to allow eight or nine feet between the hills.

The most proper season for planting hops is from the beginning of March to near the middle of April, at the time when they begin to shoot. The Kentish husbandmen approve likewise of October: but the common sorts are not to be procured then, unless it be from a ground that is to be dug up and destroyed: besides which, there is some danger in their rotting in the earth, if the winter should prove very wet.

There are several sorts, though the botanists allow but one species, of hops. The most esteemed are, the long white, the oval, and the long square garlic hop. These differ from each other in the colour and shape of their bells, or hops, in their degree of bearing, and in their time of ripening. The long white is most valued, because it is a great bearer, and produces the most beautiful hops; for the beauty of hops consists of their being of a pale bright green colour. The oval hop is beautiful, but does not yield so large a crop. There is a sort of this kind of white hop, called the early, or rath hop, which ripens a week or ten days before the common, and is therefore of advantage to those who would be first at market: but it is tenderer than the other, and does not bear near so plentifully. The long square garlic hop is the greatest bearer, more hardy, and somewhat later ripe than the former; but by reason of its redness towards the stalk, it is not so beautiful to the eye, and therefore is not so much esteemed as the other sorts.

Few hop grounds are without some plants of a sort of hop which many call the female hop, but very erroneously; for the female hop is that which is cultivated for use, and this, which others name more properly the wild hop, is the male. Towards the middle of July, it puts out a great number of

long loose bunches of small flowers, not at all like the true hop; and in somewhat less than a month after, that is to say, just before the true hop begins to blossom, they ripen, and with the least motion of the wind, shed a farina, which is wasted all around, and is by some, not improbably, thought to be of use to impregnate other hops. Those who are of this opinion advise therefore to leave one or two hills of them standing in the hop-ground. But the common practice is to mark them at their first appearance, and to root them out afterwards, because they do not bear bells or hops, and as they are generally the strongest plants, sets might otherwise be taken from them by mistake.

There is also a poor starved hop, called a wild hop, which is not judged to be a distinct sort, but a hop which has degenerated for want of culture.

The planter of hops ought to be extremely careful in the choice of his plants, or sets, particularly in regard to the kind of the hop: for it is a great trouble and loss to him when his garden proves to be a mixture of several sorts of hops, ripening at different times. He who plants the three sorts above-mentioned, viz. the early, the long white, and the square hop, in three distinct parts of his ground, will have the convenience of picking them successively as they become ripe.

Hop-sets are cuttings from the roots or branches which grow from the main root or stock. They should be procured, if possible, from grounds planted with none but the sort which is desired; and they should be from five to seven or eight inches long, with three or more joints or buds on them, all the old biad and hollow part of the set being cut off.

The ground being prepared for planting, as before directed, towards the latter end of February, or in the beginning of March, if the soil be light, or late in March if it be strong and moist, make, in the places marked out by the sticks stuck in them, holes about twelve or sixteen inches wide, and of a depth proportioned to the nature of the ground. In general, ten or twelve inches will be a sufficient depth. If the ground be shallow, and you meet with hard clay or gravel, by no means enter into this, for you would then make a basin to retain water; but, in such case, instead of going deeper, raise up a small hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half or two feet deep, and you will find the hops thrive the better; for their tap roots naturally run downward.

When all things are ready for planting, fill up the holes with the mould before thrown out of them, if it be naturally good, after having first broke it fine with a spade: but if the same earth be not rich enough, make use of fine fresh mould, or of the compost provided for this purpose. About a peck or

or two of this will be sufficient for each hill; but no new dung should be put into the hole on any account.

Then, with a dibble or setting stick, such as gardeners generally use for planting of beans, make five or six holes, the depth of your sets, one in the middle, perpendicular, and the rest round about, sloping, and meeting at the top near the center: put your sets therein, so that they may stand even with the surface of the ground; and then press the mould close to them, and cover them with fine mould two or three inches thick. A stick should be placed on each side of the hill to secure it.

The ground being thus planted, all that is to be done in the following summer, is to keep the hills and alleys clear from weeds by frequent hoeings; to dig the ground in the month of May, and to carry off all the stones that are turned up by digging; to raise a small hill about the plants; to throw some fine mould on their roots; and in the latter end of May, or beginning of June, to twist all the vines and branches together into a bunch or loose knot, and lay them thus twisted on the top of the hill.

Towards the latter end of February, or in the beginning of March, in the second year, when the weather is kindly, open the hills, and with a sharp knife cut off the shoots of the first year to within an inch of the old stock, together with all the younger suckers that have sprung from the sets, and cover the stock with fine earth. To keep the knife sharp, you should have a whetstone always by you at dressing.

In the third and following years, when you dig your hop-ground in February, let the earth be taken away with a spade, or hoe, round about the hill, very near them, that you may the more conveniently come at the stock to cut it: then in fair weather, towards the beginning of March, if your hops be weak, begin to dress them; but if they are strong, and in heart, the middle or latter end of March will be the best time; for late dressing restrains their too early springing, which is the cause of many injuries to the hop.

After the hops are dressed in the second year, the next business is to pole them. Poles of only ten or twelve feet long will do then; but in the third year, by which time they come to their full bearing state, they will require poles of full size: this, if the ground be rich, and the hop vigorous, will be from sixteen to twenty feet, or even more; or there will be danger of losing great part of the crop.

If the hop be weak, and the ground not rich, the poles should not be more than fourteen or eighteen feet long, for fear of impoverishing the root; for the hop will soon run itself out of heart if over poled; so that, as was said before, there is more danger in over-poling than in under-poling: neither can a good crop be expected from an over-poled ground, because the branches which bear the hops grow very little till the buds have over-reached the poles, which

they cannot do when the pole is too long. Two small poles are sufficient for a hill in a young ground.

Towards the latter end of July, hops begin to blossom, about the beginning of August they bell, and in forward years, they are sometimes ripe at the end of August, or beginning of September. When they begin to change colour, or are easily pulled to pieces, when they emit a fragrant smell, and when their seeds begin to look brown and to grow hard, you may conclude that they are ripe: then pick them with all expedition; for a storm of wind will do them great mischief at this time; and hops picked green and bright, without bruising or discolouring, will sell for a third part more than those that are otherwise.

When the poles are drawn up in order to be picked, the vines around them should be cut asunder at the height of about three or four feet from the ground; for the cutting of them lower, especially while the hops are green, would occasion so great a flowing of the sap, as would weaken and hurt the root.

The most convenient way of picking them is into a long square frame of wood, called a bin. This frame is made of two poles, or pieces of wood, each nine or ten feet long, and three or four inches broad, joined together at about a foot and a half from each end, by two other pieces three feet long; and it is supported by four legs three feet and a half high; so that there remain in the middle of it a space six feet long, three wide, and three and a half deep. In this space is fixed a coarse linen cloth, or hop-bag, cut open on one side, and hung hollow, either by hitching it on tenter-hooks along the side of the frame, or by stretching it on the outside with wooden skewers, to receive the hops as they are picked. Three men or women, or four boys or girls, may stand at each side of the frame, and pick two poles at a time.

The hops should be picked as free as possible from leaves and stalks; for these would be of greater prejudice to the sale, than any seeming advantage which might be expected from their weight. The bin should be emptied two or three times a day, into a large cloth of coarse linen, in which the hops should be immediately stitched up with skewers, and carried directly to the oast, or kiln, to be dried; for if they remain long in the bin, or cloth, they will sweat and be discoloured; but if you cannot dry them immediately, and must keep them a little while, spread them on a floor, and by that means the damage which they will receive in a day or two will not be great.

In drying of hops, first lay the hair-cloth very even on the bed or floor of the kiln, and spread the green hops thereon, about six inches thick, laying them with a rake as smooth as possible, not thicker in one place than another. Let the kiln be moderately warmed before you lay on the hops; then keep an even

even and steady fire under them, but not too fierce at first, for fear of scorching them; and let not the fire slacken, but rather increase it, till the hops are nearly dried, lest the moisture or sweat, which the fire has raised, fall back and discolour the hops. After the hops have lain thus about seven, eight, or nine hours, have left off sweating, and leap up when beaten with a stick, then turn them upside down with a broad malt shovel, or scoop made for that purpose, or cast them up into a heap in the middle, and afterwards spread them equally on all sides. Let them remain in this situation for two or three hours more, till every hop, if possible, be thoroughly and equally dried; and then with a hair-cloth, remove them to the heap where they are to lie till they are bagged.

Hops break all to a powder if they are bagged hot from the kiln. To prevent this, they should be laid in a heap, to sweat and grow tough; and if they are then covered for a while close with blankets, to keep the air from them, they will bag the better. There is no limited time for their sweating; that varying according to the weather, three or four days are commonly sufficient; but it is a certain rule, that when the hops feel moist and clammy, and can be squeezed in the hand, or trodden close, without breaking, they are then fit for bagging. The harder they are trodden, the better they will keep.

The bags proper for this occasion are made of coarse linen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about two hundred and a half weight of hops. The small bags, called pockets, contain about half that weight.

The manner of bagging is thus: make a round or a square hole, but a round one is most convenient, about twenty-six or thirty inches over, in the floor of the chamber where the hops are laid in heaps after they are sweated. This hole should be large enough to receive the bag, and for a man to go up and down it with ease. Tie with a piece of packthread a handful of hops in each lower corner of the bag, to serve as handles for the more easy lifting or removing of the bag; and, with packthread, fasten the mouth of the bag to a frame, or hoop, somewhat larger than the mouth of the hole, that the hoop may rest on its edges, and strong enough to bear the weight of the hops when the bag is full, and of the man who treads them. The upper part of the bag being thus fixed by the hoop, let the rest of it hang down through the hole; but not so near to the lower floor as to touch the ground: then throw into it a bushel or two of hops; and let a man go into the bag, and with shoes that have no heels, tread the hops down on every side, as hard as he can, till they lie close. Let more hops be then cast into the bag, and be trodden down, as before; and continue this till the bag is full. When that is done, untie it from the hoop, let it down,

and sew up its mouth as close as you can, observing at the same time to tie up some hops in the upper corners, as was done before in the lower.—The harder the hops are pressed, and the closer and thicker the bag is, the longer and better the hops will keep.

**HOPPER**, a kind of basket wherein the seed-corn is 'carried' at the time of sowing. See the article **SOWING**.

It is also used for the wooden trough in a mill, into which the corn is put to be ground. See the article **MILL**.

**HORARY**, something relating to an hour: hence

**HORARY**, or **HOURLY-CIRCLE** of a *Globe*, is a small brazen circle, fixed upon the brazen meridian, divided into twenty-four hours, having an index moveable round the axis of the globe, which upon turning the globe fifteen degrees, will shew what places have the sun an hour before or after us. See **GLOBE**.

**HORARY CIRCLES**, or **LINEs**, in dialling, are the lines or circles which mark the hours on the sundials. See **DIAL**.

**HORARY MOTION** of the *Earth*, the arch it describes in the space of an hour, which is nearly fifteen degrees, though not accurately so, as the earth moves with different velocities, according to its greater or lesser distance from the sun. See **EARTH**.

**HORD**, in geography, is used for a company of wandering people, who have no settled habitation, but stroll about, dwelling in waggons, or under tents, to be ready to shift as soon as the herbage, fruit, and the present province is eaten bare: such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdom of Astracan and Bulgaria.

A hord consists of fifty or sixty tents, ranged in a circle, leaving an open place in the middle. The inhabitants of each hord usually form a military company or troop, the eldest of which is commonly the captain, and depends on the general or prince of the whole nation.

**HORDEOLUM**, *Crispe*, or *Barley-Corn*, so called from its resemblance to that grain, in medicine, a tumour that grows in different parts of the eye-lids; it is commonly called a sty. When it is small, it comes only on the edge of the eye-lids, or very near it between the cilia; but when it is larger, it spreads towards the middle of the lid. In their beginning, an inflammation commonly accompanies these tumors: when they do not suppurate, their matter is concreted, and they become wens, which are sometimes soft and sometimes very hard. Sometimes this disease disappears a while, and afterwards returns in a few days.

The cure of this disease is suited to the different circumstances that attend it. If there be an inflammation, the pulp of a roasted apple applied by way

of poultice, soon disperses it, and sometimes only abates the tumor. If it hardens, it must be opened with a lancet, and the hard flesh consumed by a liquid caustic, and afterwards the plaster of the abbot de Grace applied.

If the hordeolum comes on the lower eye-lid, it is generally more on the inside than the outside, and is cured by the lapis infernalis, or rather by making an incision therein, drawing out the tumor and applying a collyrium of ten parts of water to one part of spirit of wine.

There are other little tumors on the edges of the eye-lids, which by reason of their whiteness and hardness are called chalazæ; as also another sort, called lithiasis or gravel-stone. All which are cured in the same manner.

**HORDEUM**, barley. See **BARLEY**.

**HOREHOUND**, *Marubium*, in botany. See **MARUBIUM**.

**HORIZON**, in astronomy, a great circle of the sphere, dividing the world into two hemispheres, the one upper and visible the other lower and invisible.

The horizon is either rational or sensible.

*Rational, True, or Astronomical* **HORIZON**, called generally the horizon, is a great circle, whose plane passes through the center of the earth, having the zenith and nadir for the poles thereof. It divides the sphere into two equal parts, or hemispheres.

The meridian and vertical circles all cut the rational horizon at right angles, and into two equal parts.

*Sensible, Visible, or Apparent* **HORIZON**, is a lesser circle of the sphere: this circle divides the visible part of the sphere from the invisible, and has for its poles the zenith and nadir; consequently the sensible horizon is parallel to the rational; and it is cut at right angles, and into two equal parts, by the verticals.

**HORIZON**, in geography, is a circle passing over the earth, and dividing the visible part of the earth and heavens from that which is invisible.

The altitude or elevation of any point of the sphere, is an arch of a vertical circle, intercepted between it and the sensible horizon.

This is peculiarly denominated the sensible horizon, to distinguish it from the rational, or true, which passes through the center of the earth, as already observed.

F. Lavel, professor of hydrography at Marseilles, found that the arch of the circumference of the earth intercepted between the observatory to the seaward and the horizon, fluctuated between fifteen minutes and thirteen minutes and a half: whence M. Cassini deduces that the extent of the horizon is seven French leagues, of three miles each; and that the observatory is 175 feet high.

**HORIZONAL**, something relating to the ho-

rizon; or that is taken in, or on a level with the horizon: thus we say, an horizontal plane, &c.

**HORIZONTAL DIAL**, that drawn on a plane parallel to the horizon, having its style elevated according to the altitude of the pole, in the place it is designed for. See the article **DIAL**.

**HORIZONTAL DISTANCE**. See the article **DISTANCE**.

**HORIZONTAL LINE**, in perspective, a right-line drawn through the principal point parallel to the horizon; or it is the intersection of the horizontal and perspective planes. See the article **PERSPECTIVE**.

**HORIZONTAL PARALLAX**. See **PARALLAX**.

**HORIZONTAL PLANE**, that which is parallel to the horizon of the place, or nothing inclined there-to.

The business of levelling is to find whether two points be in the horizontal plane, or how much the deviation is.

**HORIZONTAL PLANE**, in perspective, a plane parallel to the horizon passing through the eye, and cutting the perspective plane at right angles.

**HORIZONTAL PROJECTION**. See the articles **PROJECTION** and **MAP**.

**HORIZONTAL RANGE**, or *Level Range*, of a piece of ordnance, is the line it describes when directed parallel to the horizon.

Dr. Halley has given us the two following useful theorems:

1. A shot being made on an inclined plane, having the horizontal distance of the object it strikes, with the elevation of the piece, and the angle at the gun between the object and the perpendicular, to find the greatest horizontal range of that piece loaded with the same charge of powder, that is, half the latus rectum of all the parabolas made with the same impetus.—Take half the angle contained between the object and nadir, and the difference of the given angle of elevation from that half; subtract the versed sine of that difference from the versed sine of the angle made by the object and zenith: the difference of those versed sines will be to the sine of the angle last mentioned, as the horizontal distance of the object struck to the greatest range at forty-five degrees.

2. Having the greatest horizontal range of a gun, the horizontal distance and angle of inclination of an object to the perpendicular, to find the two elevations necessary to strike that object.—Take half the angle contained between the object and nadir, this half is equal to half the sum of the two angles of elevation sought; then say, as the horizontal range is to the horizontal distance of the object, so is the sine of the angle of inclination to a fourth proportional; which fourth, being subtracted from the versed sine of the angle formed by the object and zenith, leaves the versed sine of half the difference of the angles of elevation, whose half sum was before obtained;

obtained; therefore, by adding and subtracting half the difference of the angles of elevation to and from the said half sum, the elevations themselves will be found. See the article PROJECTILE.

**HORIZONTAL REFRACTION.** See the article REFRACTION.

**HORMINUM**, clary, in botany. See CLARY.

**HORN**, *Cornu*, in phisiology, a hard substance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

**HORN** is also a musical instrument of the wind kind, chiefly used in hunting, to animate the hunters and the dogs, and to call the latter together.

The French-horn is bent into a circle, and goes two or three times round, growing gradually bigger and wider towards the end, which in some horns is nine or ten inches over.

**HORN**, in architecture, sometimes denotes a volute. See VOLUTE.

**HORNS of Insects**, the slender oblong bodies projected from the heads of those animals, and otherwise called antennæ, or feelers.

**HORNBEAM**, *Carpinus*, in botany, a genus of plants producing male and female flowers, which are apetalous; the male flowers are arranged into a cylindrical amentum, and the female are disposed in the same form; there is no pericarpium, but the amentum growing very large, contains, at the base of each squamula, an oval angulated nut.

The common hornbeam grows in many parts of England, and will thrive upon the most cold, barren, and exposed hill, where few others will grow. It is best raised from seeds, which should be sown in autumn soon after they are ripe, and afterwards treated as other forest trees. The leaves of this sort remain on the tree till spring, so that they afford much shelter for the birds in winter; and this renders them very proper to be planted round the borders of other plantations in exposed situations, where they will defend the other trees in winter, and thereby greatly promote their growth.

The timber of this tree is very tough and flexible, and therefore might be converted to many useful purposes, when suffered to grow to a proper size: the principal uses it has hitherto been applied to is turnery ware, for which it is excellent; and also for mill-cogs, beetle-heads, &c.

**HORN-WORK**, in fortification, a sort of out-work, advancing towards the field, to cover a curtain, bastion, or other place suspected to be weak, as also to possess an eminence, &c.

It consists of two demi-bastions joined by a curtain; its flanks are usually parallel, though, sometimes, they contract towards the place, forming a queue d'yronde, or swallow's tail. When the flanks are too long, sometimes epaulements are made to flank them. The parts next the country

are to be defended by a parapet. Two horn-works joined together make a crown-work.

**HORNET**, *Crabo*, in zoology, a species of apis with a black thorax, and double black spots on the segments of the body. See the article APIS.

**HOROGRAPHY**, the same with dialling. See the article DIAL.

**HOROLOGIUM**, a general name for instruments to measure the hours, as a watch, clock, dial, &c. See the articles WATCH, CLOCK, &c.

**HOROPTER**, in optics, a right line drawn through the point where the two optic axes meet, parallel to that which joins the centers of both the eyes.

**HOROSCOPE**, in astrology, the point of the heavens rising above the eastern point of the horizon, at any given time when a prediction is to be made of a future event; as the fortune of a person then born, the success of a design, &c.

It also denotes a figure of the twelve houses, or twelve signs of the zodiac, wherein the disposition of the heavens is marked for the time given.

**Lunar HOROSCOPE**, the point from whence the moon proceeds when the sun is in the ascending point of the east.

**HORSE**, *Equus*, in zoology, a well known quadruped, the characters of which are these: the fore-teeth are six in number, the upper ones incurvated, and the inferior prominent: the canine teeth are not exerted, and are on each side separated by a space from the teeth: the hoof is undivided, and the teats are two, and placed in the groin.

The horse is one of the noblest quadrupeds we are acquainted with. In strength and natural fierceness, he is inferior to few, and yet easily tamed. The head is long and large; the eyes large and prominent; the ears erect and beautiful; the neck is long and thick, and elegantly decorated with a mane; the body is rounded and beautifully turned; the legs are strong, without being bulky; and the tail is long, and hairy all the way; the hairs being like those of the mane, only longer, thicker, and more beautiful.

Though the most experienced horsemen are not always agreed in some points relating to the shape, make, and goings of a horse, yet they almost always accord in this, that there ought to be a just proportion in all his parts. That even when he is taken to pieces, and examined singly in his particular members, though some defects may appear, yet when they all bear a just correspondence one to another, and concur in such a manner as to render his action easy, just, and regular, such a horse cannot be greatly disagreeable, but will, for the most part, move well, and with a tolerable good grace. On the other hand, suppose a horse has some parts exquisitely fine, and others indifferent, which frequently happens, it will mar his beauty, and cause him

him to look disagreeable, and for the most part affect his gait and action.

In order to have a horse beautiful and finely made, it has been agreed on all hands, that his head should not be long nor too large, rather lean than fleshy; his ears thin and narrow, and of a becoming length, well set on, pointing inwards; his brow or forehead not too broad and flat; his nose somewhat rising, and of a good turn; his nostrils wide and thin; his muzzle small; his mouth neither deep nor too shallow; with a star or snip down his forehead, or a blaze, which is no way unbecoming, unless it be too large and disproportioned.

Horses that are thus marked, have generally one or more of their feet white, which is also very beautiful, and looks lively. His jaws should be thin and sufficiently wide, not approaching too near together, nor too high upwards towards the onset, that he may have sufficient room to carry his head easy, and in good place; his eyes well formed, sprightly, and of a middle size; his neck should be arched towards the middle, arising by a beautiful gradation out of his breast and shoulders, the muscles thereof distinct, but no where overcharged with flesh, growing smaller and thinner as it approaches towards his head; his shoulders should be thin from the withers, with a gradual enlargement downwards, that his bosom or breast be not too narrow nor too gross; his fore-legs straight and well placed; his joints lean and bony; his knees not bending, and his pasterns not too long; his feet round and smooth, and his sinews firm and well braced; his carcase rather round than flat; his back not too low, and for strength and durability pretty even and straight; his ribs rather home than open, as they approach towards his haunches; his buttocks round, and the muscles not too fleshy, but distinct; his hocks or gambrels neither standing too wide nor too near together; his hocks should be lean and no wife puffed or fleshy; his pasterns short, his legs flat and thin; and his tail set on in a good place, rather high than low, rising upon every motion of his body. The more these properties concur in any horse, the more beautiful he must be, especially when they correspond and agree in due proportion, one to another; and the more a horse is wanting in these, the more plain an ordinary he will appear.

**HORSE-CHESNUT**, *Esculus*, in botany, a tree with digitated leaves; the flowers grow in beautiful spikes, and come out in May, each consisting of five roundish petals, with narrow unguis inserted in the cup: the stamina are seven subulated filaments topped with rising antheræ: the fruit is a coriaceous roundish capsule beset with spines, opening with three cells, in which are contained one or two globular nuts, of a bright mahogany colour.

This tree was formerly planted in avenues: the grandest we know of is in Bushy-Park; but they have a much better appearance when planted singly,

as the natural growth of them is obtusely pyramidal, the under branches being always greatly extended, and the succeeding ones gradually decreasing to the top.

It is propagated by planting the nuts early in the spring, and afterwards managed like the common chesnut, observing, in transplanting them, not to shorten any of the branches.

Horse-chesnut trees were originally brought from Constantinople to England; and although they are natives of so warm a climate, yet they resist the cold of the severest winters we have here, and grow to be very large.

The fruit of this tree is very bitter, and the only use they are applied to here, is to feed deer, who are very fond of them; so that in large parks it is very proper to have a number of horse-chesnut trees, as they are not only ornamental but useful.

**HORSE-DUNG**, in gardening, is of particular use for hot-beds; whereby cucumbers, melons, asparagus, fallads, and other delicacies, are attained early in the spring; for which purpose no other sort of dung will do so well, if mixed with litter and ashes, as this; and when rotten will make a good manure for cold lands.

**HORSE-RADISH**, a well known species of cochlearia; it is propagated by cuttings or buds from the sides of the old roots; the season for this work is in October or February, the former for dry lands, and the latter month for wet: the ground where they are designed to be planted should be well trenched and broke, after which a trench should be made a foot deep, in the bottom of which the sets should be placed with their buds upwards, at about four or five inches asunder, covering them with the earth which comes out of the next trench, and so continuing on till the intended piece of ground is finished. The second year the roots will be fit for use.

**HORSE-SHOE**, in fortification, is a small work sometimes of a round and sometimes of an oval figure, inclosed with a parapet, sometimes raised in a moat or ditch, or in low grounds, and sometimes to cover a gate, or to serve as a lodgment for soldiers.

**HORSE-SHOE-HEAD**, a disease in infants, in which the futures of the skull lie too open.

This is commonly a sign of a weak constitution, and a short life. The nurses usually embrocate the parts affected with brandy or rum, to which some add the white of an egg, or palm oil.

**HORSE-TAIL**, in botany. See *EQUISETUM*.

**HORSE**, in a military sense, the same with cavalry. See the article *CAVALRY*.

The light-horse, in an army, are all the regiments of horse, except the guards.

**HORSE**, among seamen, a rope fastened to the yards in two places, for the men to tread on, and secure

secure themselves by, as they go out on the yard-arms to furl, reef, or loosen the sails.

**HORSE** is also a rope drawn very tight perpendicularly close to the mast to hoist some sail upon, as the try-sail of a ship, the square-sail of a schooner, &c.

**HORSE** is likewise a name given by seamen to a short reed thrust into the bung of a cask, or keg, to draw off brandy, gin, &c.

**HORTICULTURE**, the same with gardening. See **GARDEN** and **GARDENING**.

**HORTUS SICCUS**, a dry-garden, an appellation given to a collection of specimens of plants carefully dried and preserved.

**HOSANNA**, in the Hebrew ceremonies, a prayer which they rehearsed on the several days of their feast of tabernacles.

The word is Hebrew, and literally signifies *save us now*, or, *save us, we pray*.

**HOSE**, in commerce. See the article **STOCKING**.

**HOSEA**, a canonical book of the Old Testament, so called from the prophet of that name, its author, who was the son of Beri, and the first of the lesser prophets. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jereboam II. and his successors, kings of Israel, and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal design is to publish the gross idolatries of the people of Israel and Judah, to denounce the divine vengeance against them, and to foretel the captivity in Assyria.

**HOSPITAL**, a place or building properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless.

**Camp-HOSPITALS** are either general or regimental. The general hospitals are of two kind, viz. the flying hospital, attending the camp at some convenient distance; and the stationary hospital, which is fixed at one place. In the choice of both, Dr. Pringle thinks it better to have them in towns than villages, as the former will afford larger wards, besides more of other conveniencies. These wards should be as airy as possible. Regimental hospitals are of the greatest importance, and therefore should be supplied with blankets and medicines from the public stores, with an allowance also for nurses and other necessaries. Barns, stables, granaries, and other out-houses, but above all, churches, make the best hospitals from the beginning of June to October.

**HOSPITAL-FEVER**, a name given to a malignant catarrhal fever, as being frequent in hospitals. See the article **MALIGNANT FEVER**.

**HOSPITALLERS**, an order of religious knights, now known by the title of the knights of Malta. See the article **MALTA**.

**HOST**, *Hospes*, denotes either a person who entertains another, or the person so entertained; but it is now generally used in the first of these senses.

**HOST**, or **HOAST**, *Hoflia*, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer; which they pretend to offer up every day, a new host or sacrifice, for the sins of mankind.

**HOSTAGE**, a person given up to an enemy as a security for the performance of the articles of a treaty.

**HOSTILITY** denotes a state of war or enmity between two nations.

During a truce all acts of hostility are to cease on both sides.

**HOT-BATH**. See the article **BATH**.

**HOT-BEDS**, in gardening, beds made with fresh horse-dung, or tanners bark, and covered with glasses to defend them from the cold winds.—By the skilful management of hot-beds we may imitate the temperature of warmer climates, by which means the seeds of plants brought from any of the countries within the torrid zone may be made to grow and flourish. Beds made of horse-dung are proper to make the seeds of different plants to come up soon, particularly those that require a very strong heat; but as this heat is not so permanent as that of tanners bark, the last mentioned is to be preferred. As to the method of making hot-beds, it is better seen than described, as is likewise the management of them.

**HOT-HOUSE**, in salt-making, the place where they dry the salt, when taken out of the boiling pan: it is situated near the furnace, which, by means of funnels or tubes, conveys a heat into it.

**HOT-HOUSE**, or stove, in gardening, a conservatory for the preservation of tender exotic plants. In plate LXII. is exhibited a view of a hot-house peculiarly adapted for raising and bringing to perfection the ananas, or pine-apple. In the ground plan *aaaa*, are four pits for containing the bark, in which the plants are plunged; the two middle pits are for fruiting plants, the other two may be used for small plants called Succession, or, if not, they are well adapted for melons: *bb* are the fire places, covered with sheds; the dark parts round the two inner pits represent the flues which terminate at the chimneys built over the fire places. The section and perspective view are so obvious that they require no references, as the scale will determine all the parts.

As this construction seems to be out of the common way of building of hot-houses, it may therefore be objected to; but we can see but little inconvenience in it; and as to the convenience attending the welfare of the plants, we think it better than those built in the common forms; for, in the first place, this will have the morning sun sooner, and the evening sun later, than the other sort, and likewise

*A Perspective View of a Hothouse.*

*Plan*

*Scale of Feet.*

Architectural

likewise the mid-day sun; and although the rays at that time will fall obliquely, we think it of service in very hot days, at which times the common stoves are obliged to be shaded, to prevent the plants from being burnt, but in this construction it is not necessary: also in winter, when the sun issues but little warmth except at noon, then the upright glasses in front receive the rays almost perpendicularly; whereas in the common stoves the obliquity of the glasses render the rays inefficacious, being of no other use but to transmit light. Another convenience attends this new form, that is, the air can be admitted at either side, according to the wind, or both, in very hot weather, which cannot be done by the other; and likewise in very cold weather, the windward side can be kept covered (either with canvas or shutters, which are necessary for both on nights) while the other side is open, it will therefore have both warmth and light. We must therefore be of a strong opinion, that this construction, if put in execution, will answer all the purposes intended, and shall remain in the same mind till it is proved to the contrary.

For a plan and description of one of the best common hot-houses see the article **STOVE**.

**HOTCH-POT**, in law, is used for mixing of lands given in marriage with other lands in fee which fall by descent; as where a man possessed of thirty acres of land has issue only two daughters, and after his having given with one of them ten acres in marriage, he dies possessed of the other twenty: here she that is thus married, in order to gain her share of the rest of the land, must put her part given in marriage in hotch-pot; that is, she must refuse to take the sole profits of her lands, and cause it to be mingled with the other, so that an equal division may be made of the whole between her and her sister; by which means, instead of only her ten acres, she has fifteen.

**HOTTONIA**, water violet, in botany, an aquatic plant, growing in standing waters in many parts of England; the leaves are finely winged, the flower-stalks rise a little above the water; they are naked, and towards the top have two or three whorles of flowers, each of which is monopetalous and saucer-shaped. The fruit is a globose pointed capsule, with one cell containing a number of round seeds.

**HOTTS**, or **HUTTS**, are the pounces and round balls of leather, stuffed, and tied to the spurs of fighting cocks, to keep them from hurting one another in sparring.

**HOUND**, a hunting dog, of which there are several sorts, as the grey-hound, gaze-hound, and the blood-hound.

**HOUNDS of the Mast**, in the sea-language, those parts of the upper-end or head of a mast upon which the checks are bolted to support the trussel-trees. See the articles **MAST** and **TRUSSEL-TREES**.

**HOURL**, *Hora*, a measure of time, some part of a natural day, usually a twenty-fourth and twelfth, &c. With us it is equal to the twenty-fourth part of the earth's diurnal rotation. Each hour is divided into sixty minutes, and each minute into sixty seconds, &c. Fifteen degrees of the equator answer to an hour.

The word is derived from the Latin *hora*, which signifies the same thing.

The ancient Hebrews did not divide the day into hours, but into four parts, as morning, high-day or noon, midnight, and morning watch. In the New Testament we find the day divided into twelve hours; but though they were equal to each other, yet they were unequal with respect to the different seasons: thus the twelve hours of the longest day in summer were made longer than those of the shortest days in winter. Herodotus says, that the Greeks learned from the Egyptians the method of dividing the day into twelve parts, the rise of which custom among the latter was, because their priests were wont, twelve times a day, to cry aloud with a howling noise to their cynocephalus; and Cicero and Marius Victorinus have taken notice of such a ceremony to Serapis.

Censorinus observes, that the word hour was not known among the Romans three hundred years after the building of the city, as there is no mention made of it in the twelve tables, as is done in the other laws after that time; before which, the divisions were only before and after noon. The division of the day and night into twenty-four hours was not known among them before the first Punic war. They divided the twelve hours of the day into four parts, as prime, which began at six o'clock; third, at nine; sixth, at twelve; and ninth, at three. They also divided the night into four watches, each watch containing three hours.

The Turks not having any clocks, their priests, stopping their ears with their fingers, proclaim with a very loud voice from the top of their mosques, the cock-crow, break of day, noon-tide, three o'clock, and the twilight. The same custom we find prevailed among the Romans, as appears from Martial;

*Horas quinque, puer, nondum tibi nunciat.*

The astronomers of Cathaya, &c. still retain, according to bishop Beveridge, the division of the day into twelve parts, and give the name of some animal to each hour.

Hours are divided into equal and unequal; equal hours are the twenty-fourth part of a day and night precisely; that is, the time when  $15^{\circ}$  of the equator mount above the horizon; they are also called equinoctial hours, as being measured on the equinoctial; and astronomical, because used by astronomers, and reckoned from noon in a continued series of twenty-four.

**HOUSE**, *Domus*, a habitation, or place built with conveniences for dwelling in: thus we say, a town-house, country-house, &c.

**HOUSE-BOTE**, in law, an allowance of timber out of the lord's woods, for the repairs of a house: this is otherwise called *estovers*.

**HOUSE**, in astrology, denotes the twelfth part of the heavens.

**HOUSE-BREAKING**, or **ROBBING**, is the breaking into and robbing a house in the day-time; the same crime being termed burglary, when done by night; both are felony, without benefit of clergy.

**Green-House**. See the article *GREEN-House*.

**HOUSE-LEEK**, *sedum*, in botany. See the article *SEDUM*.

**HOUSING**, among bricklayers, a term used for a tile or brick that is warped, or cast crooked or hollow in burning.

Tiles are apt to be housing or hollow on the struck side, or that which was uppermost in the mould, and bricks on the contrary side.

**HOUSTONIA**, in botany, a genus of plants whose flower is monopetalous and funnel-shaped, with four stamina. The fruit is a roundish bivalvular capsule, with two cells, each containing a single seed.

**HOWKER**, in the Dutch marine, a vessel with two masts, used in the coasting trade.

**HUCKSTER**, a person who sells provisions, or small ware, by retail.

**HUE AND CRY**, in law, the pursuit of a person who has committed felony on the highway.

If the party robbed, or any in the company of a person either robbed or murdered, go to the constable of the next town, and require him to raise hue and cry, and to pursue the offender, describing him, and giving an account as near as he can, of the course he steered; the constable is immediately to call upon the parish for aid in seeking after the felon; and if he cannot be found within the bounds of that parish, then he is to give the next constable warning; and he the next, till the offender be apprehended, or at least pursued to the sea side. If persons are not ready at the summons of the sheriff, and cry of the county, to engage in the pursuit, they may be fined: and in case the inhabitants of any hundred, after hue and cry is made, neglect to pursue the same, they shall be liable to pay one half of the damages recoverable against the hundred in which the robbery was committed.

**HUGONIA**, in botany, a genus of plants, whose flower consists of five large roundish patent petals, with ten subulated filaments topped with twin antheræ. The fruit is a globose drupe, containing a hard striated nut.

**HUGUENOTS**, a name given by way of contempt to the Calvinists of France.

The name had its rise in the year 1560; but authors are not agreed as to its origin. The most

plausible opinion, however, is that of Pasquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion, that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time; from whence, as those of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots; that is, the disciples of king Hugon.

**HULK**, in the marine, an old ship of war properly fitted with a very high mast, firmly supported by various props and shrouds, to hoist in and out the masts of other men of war occasionally; also an old ship of any kind.

**HULL**, in ship-building, the hull or lower frame of a ship, exclusive of the superstructure, viz. the masts, sails, and rigging.

**HULL-TO**, the situation of a ship lying-to at sea, without any sail set. See the article *TRY-ING*.

**HUMAN**, in general, is an appellation given to whatever relates to mankind; thus we say, the human soul, human body, human laws, &c. See the articles *SOUL* and *BODY*.

**HUMANITY**, the peculiar nature of man, whereby he is distinguished from all other beings. See the article *MAN*.

**HUMANITIES**, in the plural, signify grammar, rhetoric, and poetry, known by the name of *literæ humaniores*; for teaching of which, there are professors in the universities of Scotland, called humanists. See the articles *GRAMMAR*, *RHETORIC*, &c.

**HUMBLE-BEE**, the English name of several species of apis, distinguished by their colours, black, tawny, reddish, &c. See the article *APIS*.

**HUMECTION**, in pharmacy, the moistening or preparing medicines by steeping them in water; either to soften and relax their solid parts, or to prevent the evaporation of their more subtle contents.

**HUMERUS**, in anatomy, the upper part of the arm between the scapula and elbow.

The os humeri or brachii, as it is called, is articulated at one end with the scapula, and at the other end to the ulna and radius. See the articles *ARM*, *BRACHIUM*, &c.

As to the motion of the os humeri, it is evidently the most free and extensive of that of any bone in the human body; being furnished with several flexor and extensor muscles. See the articles *FLEXOR* and *EXTENSOR*.

**HUMIDITY**, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity, and seems to be merely a relative thing depending upon the congruity of the component particles of the liquor to the pores of such particular bodies, as it is capable of adhering to, penetrating a little into, or wetting.

**HUMIDUM RADICALE**, or *Radical Moisture*, among

among physicians, seems to amount to no more than the purest and most delicate part of the nutritious matter in a condition to be assimilated.

By too much heat, as in fevers, hectic, &c. this humidity is too hastily exhausted and spent.

**HUMILIS MUSCULUS**, one of the depressor-muscles of the eye.

**HUMMING-BIRD**, *Trochilus*, in ornithology, a genus of birds, of the order of the passerines, remarkable for being the smallest of all known birds. Their beak is of a subulated figure, but fine as a thread: it is longer than the head, and not perfectly straight: add to this, that they have a fine tube or pipe, which they can extend beyond the point of the beak. Of this singular genus, there are several elegant species.

**HUMORISTS**, *Gli Humoristi*, a celebrated academy of learned men at Rome, first established by Paul Mancini. The device of this academy is a cloud; which being raised on vapours from the salt-water of the sea, returns again fresh, with this hemistich from Lucretius, *Redit agmine dulci*.

**HUMOROSI**, the name of another academy at Cortona in Italy, which must not be confounded with that of the Humorists.

**HUMOUR**, *Humor*, in a general sense, denotes much the same with liquid or fluid. See the article **FLUID**.

The ancients seem to have called the nutritious juices the radical humour; and to have constituted as a cause of diseases, a disproportion betwixt the innate heat and radical moisture or humour. They also made four humours in the blood. See the article **BLOOD**.

**HUMOURS of the Eye**, are the crystalline, vitreous, and aqueous; for a description of which, see the articles **EYE**, **CRYSTALLINE**, &c.

**HUMOUR** is also used for the peculiar temper of a person, arising from the constitution and prevalence of this or that humour. See the articles **CONSTITUTION** and **TEMPERAMENT**.

**HUMOUR**, in dramatic poetry, is esteemed a subordinate species of what is more usually called manners. See **MANNERS**.

Every passion wears two different faces; one serious and solemn, fit only for tragedy; and the other merry and ridiculous, called humour, and proper for comedy. The English poets have excelled those of all other nations in this particular; and, indeed, ours is the only language that has a name for it.

To be always witty only becomes a few characters; so that it is necessary to call in the assistance of humour, to prevent the other dramatic persons from going into the common style and manner: hence humour may be looked on as the true spirit and wit of comedy. See the article **WIT**.

**HUMULUS**, the hop, in botany. See the article **HOP**.

**HUNDRED**, *Centum*, *Cent.* is ten times ten, or the square of ten. It makes the third place from the right to the left, in the table of numeration.

The proportion of the profits in commerce is reckoned by the hundred, or so much per cent.

**HUNDRED**, *Hundredum*, *Centuria*, a certain division or part of a shire or county.

**HUNGARICUS MORBUS**, a disease so called from its being first observed in the imperial army, in 1556.

It is thought to have been a compound fever, partaking of the nature both of the bilious and malignant fevers. See **BILIOUS** and **MALIGNANT**.

**HUNGARY-WATER**, a distilled water, so denominated from a queen of Hungary, for whose use it was first prepared.

Quincy gives the following directions for making it:—Take of fresh gathered flowers of rosemary, two pounds; rectified spirit of wine, two quarts; put them together, and distil them immediately in balneo.

Or, Take of fresh tops of rosemary, one pound and a half; proof spirit, one gallon; and distil in balneo till five pints are obtained.

**HUNGER**, an uneasy sensation, which creates an appetite or desire for food. See the article **FOOD**.

Hunger is by some attributed to a sharp acrimonious humour, which vellicates the coats of the stomach; others, who deny the existence of any such liquor, attribute it to the attrition or rubbing of the coats of the stomach; and others, again, account for it from the acidity of the blood.

**HUNGRY EVIL**, among farriers, an excessive desire in horses to eat, which sometimes proceeds from catching cold, or from travelling long in frost and snow, or through barren places.

For the cure, give him great slices of bread, toasted and steeped in sack, to comfort his stomach; or give him wheat flour in wine or milk, a quart at a time. But there is nothing better than to feed him moderately several times a day with good bread well baked, or with oats well dried and sifted.

**HUNTING**, the exercise or diversion of pursuing four-footed beasts of game. See the article **GAME**.

**HUOY**, a vessel used to load and unload large ships, either in the king's or merchants service; also a small Dutch ship, with a main-mast and mizen-mast.

**HURA**, in botany, a genus of plants whose flowers are male and female, growing on the same plant; the male-flowers are apetalous, being an imbricated amentum, principally composed of cylindrical filaments, terminated with sessile anthers lying over each other: the female flower is destitute of a corolla, being composed of a swelling cylindrical calyx: the style is long, and terminated with a large funnel-shaped stigma: the fruit is an orbicular lignous

Igneous pericarpium, consisting of twelve cells, each containing a single seed of a roundish compressed form.

We know only one species of this genus, which rises with a soft woody stem, abounding with a milky juice, and furnished with heart-shaped leaves indented on their edges. It grows naturally in the West-Indies, where it is called the sand-box tree, the shells being used to contain sand for writing.

**HURDLES**, in fortification, twigs of willows or osiers interwoven close together, sustained by long stakes, and usually laden with earth.

Hurdles, called also clays, are made in the figure of a long square; the length being five or six feet, and the breadth three, or three and a half: the closer they are woven, the better. They serve to render batteries firm, or to consolidate the passage over muddy ditches; or to cover traverses and lodgements, for the defence of the workmen, against the fire-works, or the stones that may be thrown against them.

**HURDLES**, in husbandry, certain frames, made either of split timber, or of hazle-rods, wattled together, to serve for gates in inclosures, or to make sheep-folds, &c.

**HURDS**, or **HORDS**, of *Flax*, or *Hemp*, the coarser parts separated in the dressings, from the tear or fine stuff.

**HURLE-BONE**, in a horse, a bone near the middle of the buttock, very apt to go out of its sockets with a hurt or strain.

**HURRICANE**, a furious storm of wind, owing to a contrariety of winds. See the articles **WIND** and **WHIRL-WIND**.

**HUSBAND**, *Maritus*, a man joined or contracted with a woman in marriage.

**HUSBANDRY**, the business or employment of a farmer, or person who cultivates land, &c. See **AGRICULTURE**.

Husbandry is divided into two kinds, and distinguished by the epithets old and new. The former is that which has been practised in all countries from the most early times; and the latter that introduced by the ingenious Mr. Tull, and often called the horse-hoeing husbandry.

Experience shews, that land, though ever so well tilled in the autumn, when wheat, for example, is sown, hardens and fadens in the winter; its particles, beaten down by heavy rains, and sunk by their own weight, approach each other daily more and more; the roots of the plants cultivated have consequently less and less room to extend themselves in quest of their necessary food; and the interstices in the earth become of course so few and close, that they are not able to pierce through them; whilst weeds spring up, and rob them of their nourishment. By this means the earth, reduced to nearly the same condition as if it had not been ploughed at all, is unable to assist the plants sown in it, in the spring,

when they ought to shoot with the greatest vigour. They consequently then stand most of all in need of the plough, to destroy the weeds, to lay fresh earth to their roots in the room of that which they have exhausted, to break the particles of the ground anew, so as to enable their roots to spread, in order to their gathering an ample provision of food, which then does them the greatest service.

The editors of the last edition of Mr. Tull's *Horse-Hoeing Husbandry* give, in their preface to that work, the following comparative calculation of the expence and profit of the old method of culture and the new, drawn up by a gentleman who has practised both for some years, and who has no attachment to the new husbandry, farther than he has found it answer in his trials. They candidly appeal to experience, "whether every article in this calculation is not estimated in favour of the common husbandry; whether the expence be not rated lower than most farmers find it; and whether the crop be not such as they would rejoice to see, but seldom do.

"In the new husbandry, every article is put to its full value, and the crop of each year is computed four bushels short of the other; though, in several years experience, it has equalled, and generally exceeded, those of the neighbourhood in the old way."

An Estimate of the Expence and Profit of Ten Acres of Land, in Twenty years.

| I. In the Old Way.                                   |    |          |         |
|------------------------------------------------------|----|----------|---------|
| First year for wheat costs                           |    |          |         |
| 33 l. 5 s. viz.                                      |    | 1. s. d. |         |
| First ploughing, at 6 s. per acre                    | 3  | 0        | 0       |
| Second and third ditto, at 8 s. per acre             | —  | —        | 4 0 0   |
| Manure, 30 s. per acre.                              | 15 | 0        | 0       |
|                                                      |    |          | 22 0 0  |
| Two harrowings and sowings, at                       |    |          |         |
| 2 s. 6 d. per acre                                   | —  | —        | 1 5 0   |
| Seed, three bushels per acre, at 4 s. per bushel     | —  | —        | 6 0 0   |

| Reaping, binding, and carrying in, at 6 s. per acre  | —  | —        | 3 0 0   |
|                                                      |    |          | 11 5 0  |
| Second year for barley costs                         |    |          |         |
| 11 l. 6 s. 8 d.                                      |    |          |         |
| Once ploughing, at 6 s. per acre                     | 3  | 0        | 0       |
| Harrowing and sowing, at 1 s. 6 d. per acre          | —  | —        | 0 15 0  |
| Seed, four bushels per acre, at 2 s. per bushel      | —  | —        | 4 0 0   |
| Weeding, at 1 s. per acre                            | —  | —        | 0 10 0  |
| Cutting, raking, and carrying, at 3 s. 2 d. per acre | —  | —        | 1 11 8  |
| Grass-seeds, at 3 s. per acre                        | —  | —        | 1 10 0  |
|                                                      |    |          | 11 6 8  |
|                                                      |    |          | 44 11 8 |

Third and fourth years lying in  
grafs cost nothing.

So that the expence of ten acres  
in four years comes to 44*l*.

11*s*. 8*d*. and in twenty years to

First year's produce is half a load  
of wheat per acre, at 7*l*. per  
acre — — — — —

1. s. d.  
222 18 4

Second year's produce is two  
quarters of barley per acre, at  
1*l*. per acre — — — — —

35 0 0

Third and fourth years grafs is  
valued at 1*l*. 10*s*. per acre

15 0 0

So that the produce of ten acres  
in four years is — — — — —

70 0 0

And in twenty years it will be

350 0 0

Deduct the expence — — — — —

222 18 4

And there remains clear profit on  
ten acres in twenty years by  
the old way — — — — —

127 1 8

## II. In the New Way.

First year's extraordinary ex-  
pence is,

For ploughing and manuring the  
land, the same as in the old  
way — — — — —

22 0 0

Ploughing once more, at 4*s*. per  
acre — — — — —

1. s. d.  
2 0 0

Seed, nine gallons per acre, at  
4*s*. per bushel — — — — —

2 5 0

Drilling, at 7*d*. per acre — — — — —

0 5 10

Hand-hoeing and weeding, at 2*s*.  
6*d*. per acre — — — — —

1 5 0

Horse-hoeing, six times, at 10*s*.  
per acre — — — — —

5 0 0

Reaping, binding, and carrying  
in, at 6*s*. per acre — — — — —

3 0 0

The standing annual charge on  
ten acres is — — — — —

13 15 10

Therefore the expence on ten  
acres in twenty years is — — — — —

275 16 8

Add the extraordinaries of the  
first year, and the sum is — — — — —

297 16 8

The yearly produce is at least  
two quarters of wheat per acre,  
at 1*s*. 8*d*. per quarter, which  
on ten acres in twenty years,  
amounts to — — — — —

560 0 0

Therefore, all things paid, there  
remains clear profit on ten  
acres in twenty years, by the  
new way — — — — —

262 3 4

“ So that the profit on ten acres of land in  
twenty years, in the new way, exceeds that in the  
old by one hundred and thirty-five pounds, one shil-  
ling, and eight-pence, and consequently is confi-  
derably more than double thereof: an ample encou-

agement to practise a method whereby so great ad-  
vantage will arise from so small a quantity of land,  
in the compass of twenty-one years lease; one year  
being allowed, both in the old and new way of pre-  
paring the ground.

“ It ought withal to be observed, that Mr. Tull's  
husbandry requires no manure at all, though we  
have here, to prevent objections, allowed the charge  
thereof for the first year; and moreover, that tho'  
the crop of wheat from the drill-plough is here put  
only at two quarters on an acre, yet Mr. Tull him-  
self, by actual experiment and measure, found the  
produce of his drilled wheat crop amount to almost  
four quarters on an acre: and, as he has delivered  
this fact upon his own knowledge, so there is no  
reason to doubt of his veracity, which has never yet  
been called in question. But that we might not be  
supposed to have any prejudice in favour of his  
scheme, we have chosen to take the calculations of  
others rather than his, having no other view in  
what we have said, than to promote the cause of  
truth, and the public welfare.”

HUSK, the same with what botanists call the  
calyx, or cup of a flower. See the article CALYX.

HUSSARS, a kind of irregular cavalry, armed  
with the sabre and bayonet, are retained in the  
service of most princes on the continent.

HUSSITES, the disciples of John Hus, a Bo-  
hemian, and curate of the chapel of Bethlehem  
at Prague; who, about the year 1414, embraced  
and defended the opinion of Wickliff of England,  
for which he was cited before the council of Con-  
stance, and, refusing to renounce his supposed er-  
rors, he was condemned to be burnt alive, which  
sentence was accordingly executed upon him at  
Constance.

HYACINTH, hyacinthus, in botany, a genus  
of plants, whose root is bulbous, with smooth long  
leaves, which arise immediately from the root. The  
flowers are produced in spikes, placed alternately,  
each consisting of a monopetalous campanulated  
corolla, divided into six reflexed segments at the  
limb, with three nectariums, placed on the top of  
the germen. The stamina are six short subulated  
filaments, topped with connivent antheræ.

The fruit is a roundish triquetrous, divided into  
three cells, each of which usually contains two  
roundish seeds.

The double hyacinths, of which there are great  
variety, are much esteemed for their fragrancy and  
beauty. They are propagated by offsets, or from  
seeds.

HYACINTH, in natural history, a genus of pel-  
lucid gems, whose colour is red, with an admix-  
ture of yellow.

HYACINTHIA, an ancient Grecian festival, ob-  
served at Amyclæ in Laconia, in the month Heca-  
tombæon, in memory of the beautiful young Hy-  
acinthus, son of Amyclos, king of Sparta.

HYADES,

# HYD

**HYADES**, in astronomy, seven stars in the head of the bull, famous among the poets for bringing on rain both at the rising and setting.

The word is Greek, and derived from *υω*, to rain.

The principal of them is in the left eye, by the Arabs, called Aldebaran.

**HYDATIS**, in medicine, a little transparent vesicle, or bladder full of water, which is sometimes found singly, and sometimes in clusters, upon the liver, and various other parts, especially in dropical constitutions.

**HYDATOIDES**, the same with the aqueous humour of the eye. See **EYE**.

**HYDATOSCOPY**, *Hydatoscopia*, called also **HYDROMANCY**, in antiquity, a kind of divination, or method of foretelling future events by means of water.

The word is Greek, and formed of *υδατος*, the genitive of *υδωρ*, water, and *σκοπεω*, to view or consider.

**HYDNUM**, in botany, a genus of cryptogamous plants, of the order of fungi, called by Dillenius *erinaceus*. It has an horizontal fungus, echinated or beset with subulated fibres on its under part.

**HYDRA**, in astronomy, a southern constellation imagined to represent a water-serpent.

The number of stars in this constellation in Ptolemy's catalogue is twenty-five, and in the Britannic catalogue sixty-eight.

**HYDRAGOGUES**, purgative medicines that evacuate a large quantity of watery or serous humour.

The word is formed from the Greek, *υδραγωγος*, and derived from *υδωρ*, water, and *αγω*, to drive, or bring away.

In general all sudorific, aperient, and diuretic medicines are hydragogues.

**HYDRANGEA**, in botany, a genus of plants whose flower consists of five roundish equal petals, with ten stamina.

The fruit is a roundish didymous capsule; the two permanent style make two beaks to it, and is rendered angular by many ribs: it is coronated by the cup, and divided into two cells by a transverse membrane. The seeds are numerous, angular, acuminated, and very small.

**HYDRARGYRUM**, a name given to mercury or quicksilver. See the article **MERCURY**.

**HYDRASTIS**, in botany, a genus of plants whose flower consists of three ovate regular petals. The filaments are numerous, linear, compressed, and topped with obtuse antheræ. The fruit is an oblong, compound, acinated berry: and the seeds are oblong and solitary.

**HYDRAULICS**, that part of statics which considers the motion of fluids, with the application thereof, particularly in artificial water-works.

# HYD

**HYDRELÆUM**, in pharmacy, a mixture of oil and water, which Galen reckons refrigerating.

The word is Greek, and compounded of *υδωρ*, water, and *ελαιον*, oil.

Taken inwardly, it provokes vomiting; and, externally, it is anodyne, and promotes suppuration.

**HYDRENTEROCELE**, in surgery, a kind of tumor or hernia, where there is a dropfy of the scrotum, complicated with a descent of the intestine.

The word is Greek, and compounded of *υδωρ*, water, *εντερον*, an intestine, and *κηλη*, a tumor.

**HYDROCANISTERIUM**, an engine which spouts water in great quantities, and to considerable heights, in order to extinguish accidental fires in houses. See **ENGINE**.

**HYDROCELE**, *Hernia*, in surgery, a swelling or dropfy in the scrotum. See **HERNIA**.

**HYDROCEPHALUS**, in surgery, a preternatural tumor of the head arising from preternatural lymph.

It is of two sorts, internal and external; internal, when the water is collected within the bones of the cranium; external, when retained between the skin and cranium. The first kind is rarely seen but in new-born infants, who are generally in great danger: for, upon an incision, the lymph is no sooner discharged, than the infant dies, as experience has too often convinced us. If the distemper be recent, it will be more adviseable to repeat gentle purges; whilst a large compress, dipped in lime-water, spirit of lavender, or Hungary-water, is applied outwardly.

**HYDROCHARIS**, the little water-lilly, in botany, a genus of plants, the male flower of which has a spatha, and is composed of three large, plain, and roundish petals; the female flower is like the male one, only without any spatha: the fruit is a coriaceous and roundish capsule, consisting of six cells, in which are contained a great number of very small and roundish seeds.

**HYDROCOTYLE**, marsh-penny-wort, in botany, a genus of plants, the universal corolla of which is uniform in figure, though not in situation; and the single corolla are formed of five ovate-acute, patent petals: the fruit is orbicular, erect, and composed of two compressed and semi-orbicular seeds.

This plant is common with us in damp places, and is suspected of hurting sheep that feed on it; whence it is sometimes called white-rot.

**HYDROGRAPHY**, that part of geography which considers the sea as it is navigable.

The word is Greek, and derived from *υδωρ*, water, and *γραφω*, to describe.

It teaches how to measure the sea; gives an account of its tides, counter-tides, currents, soundings, bays, &c. as also its rocks, shelves, sands, promontories, harbours, distances from port to port, with

## H Y D

with every thing remarkable out at sea, or on the coast.

**HYDROMANCY**, the art of foretelling future events by means of water; the same as hydatoscopy.

The word is Greek, and formed of *υδαρ*, the water, and *μαντια*, divination.

The other kinds of divination relative to fire, air, and earth, are denominated pyromancy, aeromancy, and geomancy.

**HYDROMEL**, *Hydromeli*, among physicians, water impregnated with honey, either before or after fermentation: that made by fermentation is called vinous hydromel, or mead, and is esteemed good for the gravel. See **HONEY**.

The word is Greek, and compounded of *υδαρ*, water, and *μελι*, honey.

**HYDROMETER**, an instrument to measure the gravity, density, velocity, force, &c. of water and other fluids. See the articles **WATER** and **FLUID**.

The hydrometer is one of the most useful instruments of the philosophic kind; for though the hydrostatical balance be the most general instrument for finding the specific gravities of all sorts of bodies, yet the hydrometer is best suited to find those of fluids in particular, both as to ease and expedition.

This instrument should be made of copper, since ivory imbibes spirituous liquors, and thereby alters its gravity; and glass is apt to break. The most simple kind, used for finding the strength of spirits, consists of a copper-ball *B b* (plate LXI. fig. 3.) with a brass-wire, *AB*,  $\frac{1}{4}$  of an inch thick, folded into it. The upper part of this wire, being filed flat on one side, is marked proof at *m*, because it sinks exactly to this mark in proof-spirits. There are other two marks at *A* and *B*, to shew whether the liquor be  $\frac{1}{10}$  above or below proof, according as the hydrometer sinks to *A* or emerges to *B*, when a brass-weight as *C* or *K* has been screwed on at the bottom *c*. There are also weights to be screwed on, for shewing the specific gravities of fluids quite to common water. The round part of the wire above the ball, may be marked so as to represent river-water when it sinks to *RW*, (fig. 4.) the weight which fits the instrument for river-water being screwed on at *c*: also when put into spring-water, mineral-water, sea-water, and water of salt-springs, it will emerge or rise gradually to the marks *SP*, *MI*, *SE*, *SA*; and, on the contrary, when put into Bristol-water, rain-water, port-wine, and mountain-wine, it will successively sink to the marks *br*, *ra*, *po*, *mo*.

Another kind, which serves to distinguish the specific differences of fluids to great nicety, consists of a large hollow ball *B*, (fig. 5.) with a smaller ball *b* under it, partly filled with quick-silver or small shot, and screwed on to the lower part of the former, in order to render it but little specifically lighter than water: it has also a small short neck at

## H Y D

*C*, into which is screwed the graduated brass-wire *AC*, which by its weight causes the body of the instrument to descend in the fluid, with part of the stem.

When this instrument is swimming in the liquor, contained in the jar *ILMK*, the part of the fluid displaced by it, will be equal in bulk to the part of the instrument under water, and equal in weight to that of the whole instrument. Suppose the weight of the whole were 4000 grains, then it is evident we can by this means compare together the different bulks of 4000 grains of various sorts of fluids. For if the weight *A* be such as shall cause the aræometer to sink in rain-water, till its surface comes to the middle point of the stem *20*; and if, after this, it be immersed in common spring-water, and the surface is observed to stand  $\frac{1}{10}$  of an inch below the middle point *20*; it is evident that the same weight of each water differs in bulk only by the magnitude of  $\frac{1}{10}$  of an inch in the stem.

Now suppose the stem were ten inches long, and weighed one hundred grains, then every tenth of an inch would be one grain weight; and since the stem is of brass, and brass is about eight times heavier than water, the same bulk of water will be equal to  $\frac{1}{8}$  of a grain; and consequently to the  $\frac{1}{8}$  of  $\frac{1}{1000}$  part, that is, a 32000th part of the whole bulk, which is a degree of exactness as great as can be desired. Yet the instrument is capable of still greater exactness, by making the stem or neck consist of a flat thin slip of brass, instead of one that is round or cylindrical: by this means we increase the surface, which is the most requisite thing; and diminish the solidity, by which the instrument is rendered more exact.

In order to adapt this instrument to all sorts of uses, there ought to be two different stems to screw on and off in a small hole at *a*. One stem should be such a nice thin slip of brass, or rather of steel, like a watch-spring set straight, as we have just mentioned; on one side of which ought to be the several marks or divisions, to which it will sink in various sorts of waters, as rain-water, river-water, spring-water, salt spring-water, &c. And on the other side you mark the division to which it sinks in various lighter fluid, as hot Bath-water, Bristol-water, Lincomb-water, Chelton-water, port-wine, mountain, madeira, and various other sorts of wine. But in this case the weight *A* on the top must be a little less than before, when it was used for the heavier waters.

But, in case of trying the strength of spirituous liquors, a common cylindric stem will do best, because of its strength and steadiness; and this ought to be so contrived that, when immersed in what is called proof-spirit, the surface of the spirit may be upon the middle point *20*; which is easily done by duly adjusting the small weight *A* on the top, and making the stem of such a length that, when immersed in water, it may just cover the ball, and  
rise

rise to *a*; but, when immersed in pure spirit, it may arise to the top at *A*; then by dividing the upper and lower parts *a* 20, *A* 20, into ten equal parts each, when the instrument is immersed in any sort of spirituous liquor, it will immediately shew how much it is above or below proof.

This proof spirit consists of half water and half alcohol, or pure spirit, that is, such as when poured upon gun-powder, and set on fire, will burn all away, and permit the powder to take fire, which it will, and flash as in the open air. But if the spirit be not so highly rectified, there will remain some phlegm or water, which will make the powder wet, and unfit to take fire. This proof-spirit of any kind, weighs seven pounds twelve ounces per gallon.

The common method of shaking the spirits in a vial, and by raising a crown of bubbles, to judge by the manner of their rising or breaking away whether the spirit be proof or near it, is very precarious, and capable of great fallacy. There is no way so easy, quick, certain, and philosophical, as this by the aræometer, which will demonstrate infallibly the difference of bulks, and consequently specific gravities, in equal weights of spirits, to the 30, 40, or 50 thousandth part of the whole, which is a degree of accuracy, beyond which nothing can be desired.

**HYDROMETRY**, *Hydrometria*, the mensuration of fluids, their gravity, velocity, quantity, &c.

The word is of the same original with the preceding. It includes both hydrostatics and hydraulics.

**HYDROMPHALUS**, in medicine and surgery, a tumor of the navel, containing water. See the article **HERNIA**.

**HYDROPARASTATÆ**, a sect of heretics, the followers of Tatian.

This sect was called also Encratitæ, Apotactitæ, Saccophori, Severiani, and Aquarians.

The hydroparastatæ were a branch of the Manichees, whose distinguishing tenet was, that water should be used in the eucharist instead of wine.

**HYDROPHOBIA**, in medicine, a dread of water, which is a symptom arising in a person who has been bitten by a mad dog, or other mad animal.

The word is Greek, and compounded of *υδωρ*, water, and *φοβω*, to fear.

The symptom is not peculiar to this distemper, though it be always an attendant; for we meet with several instances of fevers accompanied with a dread of water.

In a person affected with this disorder, among other extraordinary symptoms, the approach of any liquor to the body, especially to the tongue and lips, produces an incredible uneasiness, trembling, convulsions, and a state next to direct madness; and

at the same time the patient is racked with an insupportable thirst.

In general, Boerhaave affirms, that there is no certain preservative against this disorder yet known; and that there is no example, that can be depended upon, of any one having been recovered, who was once so far gone as to dread water. This author adds, that it is much to be lamented, that after the common methods have been put in practice perpetually without success, for so many ages, others have not been tried. All the celebrated remedies for this purpose, he adds, owe their reputation either to barren speculation, or too great confidence in the reports of others.

His own directions, however, are, 1. As soon as the poison is received into the body, the part affected, and those adjacent thereto, should have deep scarifications made in them. Then large cupping-glasses to be applied, or the part to be burnt pretty deep with the actual cautery, and afterwards kept in continual suppuration. During the whole of this time, the part is, without interruption, to be fomented with a pickle of sea-salt and vinegar. 2. The cloaths, &c. which have come near the poison to be thrown away. 3. The patient is, immediately after receiving the misfortune, to be thrown headlong into the sea, or some river, with threatening words, and other circumstances capable of striking terror into him; for which purpose he is frequently to be immersed in the water, and again taken up: for the good effects are only produced by the dread and consternation into which the mind is thrown. He is frequently to be purged with rhubarb, agaric, and the juice of elder bark. 4. Let the patient have a gentle sweat excited every morning before eating. 5. His feet and hands are to be daily fomented in a bath of water. Lastly, let him frequently drink cold water, till he vomit it up: use acidulated liquors often: his diet must be moist, light, and laxative, and take them so liberally as to vomit them again. He must abstain from large quantities of aromatic substances, wine, &c. violent exercise of body, and all commotions of mind.

The cure is principally to be attempted in the first stage, or the beginning of the second. It seems probable, says he, the following method may be of some efficacy, especially as it is confirmed by some few experiments. Immediately upon the signs of approaching madness, the case is to be treated as extremely inflammatory; wherefore a large quantity of blood must be taken away by a large orifice, even till the patient is faint: then directly inject nitrous clysters, mixed with a little vinegar. Let these be repeated boldly, and more frequently than is consistent with prudence in other cases. After this, the eyes are to be blindfolded, and he thrown into a cold pond, or cold water thrown upon him, till he be no longer afraid of it. Then let him be im-

immediately forced to drink a large quantity of water; and toward the evening of the same day let a sleep be procured.

We have an account of remedies for this malady in the Philosophical Transactions; one of which is the lichen cinereus terrestris, or ash-coloured liverwort, which has been taken into the College Dispensatory, under the title of *Pulvis. Antilyssus*, and is the celebrated remedy published by Dr. Mead, with some variation in the proportion of the pepper. The directions, as made public, are, first to take away nine or ten ounces of blood; and then take of powdered ash-coloured liverwort, four drams, and of the powder of black pepper, two drams: mix these together, and divide into four doses; one of which is to be taken fasting for four days successively, in half a pint of tepid cow's milk. After taking these four doses, the patient is to be put fasting every morning for a month, either into a cold bath, cold spring, or river, remaining therein with his head above water, not longer than half a minute, if the water be excessively cold. Then let him bathe thrice a week for fifteen days.

Boerhaave, in his Aphorisms, treating of the canine madness, would have us not to despair of discovering a peculiar antidote against this singular kind of poison: and this, says he, we are encouraged to hope for, from the certain instances we already have of remedies effectual against particular sorts of poison. Accordingly he had a mind to try what effect mercury would have upon animals under canine madness; and from several experiments, he found it prove successful, by administering some grains of turpeth mineral made into boluses. He also mentions the remedy which M. Desault tried with constant success in the hydrophobia, which is a mercurial ointment made of one third part of mercury revived from cinnabar, one third part of human fat, and as much of hog's lard. One or two drams of this ointment at a time should be rubbed by intervals, or successively, upon and about the wound. As a farther confirmation of the efficacy of mercury in the canine madness, he takes notice of a medicine Mr. Cobb, of Busselton, near Bristol, brought from Tonquin, which is much celebrated in the East-Indies as efficacious in this distemper; this is a native and factitious cinnabar, of each twenty-four grains; musk sixteen grains, powdered and mixed well together. This powder is to be taken all at once in a tea-cup of arrack, which is said to secure the patient for thirty days: after which time the dose is to be repeated in the same manner; but it should be done as soon as possible after the bite is received: but if the patient have any symptoms of the disease, the second dose must be repeated three hours after the first; and this is said to be sufficient for a cure.

**HYDROPHYLLUM**, in botany, a genus of plants, whose flower consists of a monopetalous

campanulated corolla, divided into five segments; the stamina are composed of five subulated filaments terminated by oblong incumbent antheræ. The fruit is a globose unilocular capsule, with two valves, inclosing a large roundish seed.

**HYDROPIA**, a dropical patient; or a person swelled and bloated with abundance of water. See the article **DROPSY**.

**HYDROPOTA**, in medicine, a person who drinks nothing but water.

It has long been controverted among physicians, whether or no the hydropotæ live longer than other persons.

**HYDROPS**, in medicine, the same with dropsy. See the article **DROPSY**.

**HYDROSCOPE**, an instrument anciently used for the measuring of time.

The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom; the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out at the vertex of the cone, pointed out the hour. See **CLEPSYDRA**.

**HYDROSTATICAL BALLANCE**, a kind of ballance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid. See the article *Hydrostatical* **BALLANCE**.

**HYDROSTATICS**, that part of mechanics which considers the gravity and æquilibrium of fluid bodies, particularly water, and of solid bodies immersed therein.

The word is Greek, and compounded of *υδωρ*, water, and *στατην*, the science of weights, which is derived from *ιστηναι*, to establish or determine.

Mr. Boyle has applied hydrostatics in examining and proving the goodness and purity of metals, minerals, &c. particularly fluids, in his *Hydrostatica*. See *Hydrostatical* **BALLANCE**.

As to the laws of hydrostatics, with the application thereof, see **FLUID**.

**HYGIEINE**, that branch of medicine which prescribes rules for the preservation of health; it may be divided into prophylactice, which foresees and prevents diseases; synergetice, employed in preserving health; and analeptice, whose office is to restore health.

The word is Greek, *υγιεινη*, and derived from *υγις*, sound.

**HYGROMETER**, or **HYGROSCOPE**, a machine whereby to measure the degrees of dryness or moisture of the air.

The word is Greek, and compounded of *υγρος*, moist, and *μετρον*, to measure.

In the Philosophical Transactions we have several methods of constructing hygrometers.

Mr. Molyneux gives the following:—AB (plate LXIII fig. 1.) is a whipcord about four feet long, tied fast to the end of the hook A. At the end of this

This whiptcord hangs the weight *C*, about a pound, or something more: this weight is so fitted at the end to receive and carry the index *D*. Under these there is placed a graduated circle on the board *E F*, fixed by a bracket against the wall.

The moisture of the air twists the cord, and gives a motion to the index over the divisions in the graduated circle; and again, as the air grows more dry, the cord untwists, and brings back the index by a contrary motion. The rope *A B* shortens and lifts up the weight *C* by way of a screw, and consequently must give a circular motion to the index.

One of the grand defects of all hygrometers, hitherto invented, is, that they grow weak with age, and do not so nicely obey the alterations of the air. The alterations also of the air may give this kind of hygroscope more than one turn. To remedy this, the index *D* has two complete turns: the point *A*, as being fixed, has no turn; therefore the middle point *G* has but one turn; and consequently, if it be hung up at the point *G*, or no longer than *G D*, half the former length, the index *D* will have but one turn. What is here said of two turns, and the middle point *G*, may be accommodated to any other number of turns and points in the cord.

Mr. Gould observes, that when oil of vitriol is saturated in the moistest weather, it afterwards retains or loses its acquired state, as the air proves more or less moist. Thus one grain, after its full increase, often varied the equilibrium so sensibly, that the tongue of the balance of  $1\frac{1}{2}$  inch long, described an arch of variation to  $\frac{1}{3}$  of an inch compass; which arch would have been  $2\frac{2}{3}$  inches, had the tongue been but one foot in length, even with that little quantity of liquor: so that, if more liquor expanded under a large surface be made use of, the minutest alteration of weather must needs very much affect it; and a bare pair of scales will afford a hygroscope as nice, perhaps, as any yet known.

This balance may be contrived two ways; either such whose pin should be in the middle of the beam (*fig. 2.*) with a very slender tapering tongue of a foot or a foot and a half long, pointing to the divisions on a broad arched plate, fixed above in the handle; or else the scale with the liquor may be hung to a point of the beam (*fig. 3.*) very near the pin, and the other extreme made so long as to mark a large arch on a board placed conveniently for that purpose. The scale in either may be a concave glass of four or five inches diameter. Lastly, on the division of the arches should be inscribed the different temperature of the air shewn by the liquor.

The above author imagines oil of sulphur per campanum, as also oil of tartar per deliquium, and the liquor of fixed nitre, &c. might succeed as well as oil of vitriol.

Another hygroscope, he says, may be made of a viol string running upon pulleys, and suspending a

bullet fixed to the shorter end of an index, whose other extremity is so long as to describe a long arch by the falling and rising of the bullet upon the stretching and shrinking of the string; which would be the more nice, were the index fastened to the center.

But among all the inventions, the following seems best calculated both for dispatch and accuracy:

*A* (*fig. 4.*) represents a thin piece of sponge, so cut as to contain as large a superficies as possible. This hangs by a fine thread of silk, upon the beam *B*, and is exactly balanced from another thread of silk at *D*, strung with the smallest lead shot, at equal distances, and so adjusted as to cause the index *E* to point at *G*, in the middle of the graduated arch *F, G, H*, when the air is in the middle state, between the greatest moisture and the greatest dryness. *I*, shews a little table or shelf for that part of the silk or shot which is not suspended to rest upon.

The words hygroscope and hygrometer are commonly both used in the same sense. However, Wolfius makes some difference betwixt an hygroscope and an hygrometer, arising from the etymology; the former only shewing the alterations of the air, in respect of humidity and dryness; and the latter measuring them.

The word hogroscope is Greek, and compounded of *υγρος*, moist, and *σκοπεω*, to view, or consider.

**HYLE**, or **HYLEC**, among alchemists, denotes their first matter, or the original chaos of things.

**HYLEG**, or **HYLECH**, in astrology, signifies a planet, or the point in the heavens, which at a person's nativity, is accounted the signification of life. See the article **NATIVITY**.

**HYMEN**, in anatomy, signifies a membrane in general; but it is commonly taken for that circular membranous fold, with which the anterior extremity of the great canal in virgins, and especially before the first eruption of the menses, is commonly bordered. This fold is of different breadths, more or less smooth, and sometimes semi-lunar; and in some subject leaves but a very small opening, in others a larger; and in all renders the external orifice narrower than the rest of the cavity. The hymen is formed by the union of the internal membrane of the great canal with that on the inside of the alæ; it is commonly ruptured after the consummation of marriage; is quite lost in delivery; and afterwards only some irregular portions of it remain; which, from their supposed resemblance to myrtle leaves, have been termed *carunculae myrtiliformes*. This circle may also suffer some disorder by two great a flux of the menses and other particular accidents. *Winflow*.

**HYMENÆA**, in botany, a genus of plants whose flower is papilionaceous; the fruit is a large ligumen, or pod, of an ovato-oblong figure, with

numerous oval seeds surrounded with fibres, and a farinaceous matter.

We know but of one species belonging to this genus, which is a large spreading tree growing in plenty in the West-Indies, where it is called the locust-tree, the wood of which is esteemed as good timber as any that part of the world produces; it yields a fine clear resin (which makes an excellent varnish) and is called gum anime, in the shops. See the article ANIME.

HYMN, a religious song. The hymns sung in the Christian church, as distinguished from the psalms, are pieces of poetry composed by pious, but not inspired, authors.

HYOIDES, in anatomy, a forked bone at the root of the tongue; it is situated in the middle space between the angles of the lower jaw; it is a little bone, and resembles, in some measure, the basis of the lower jaw.

HYOSCYAMUS, henbane, in botany, a genus of plants whose flower is monopetalous and funnel-shaped; the tube is cylindrical, and the corolla is erect and spreading, lightly divided into five obtuse segments, one being broader than the rest; it hath five subulated filaments, topped with roundish antheræ. The fruit is an ovate obtuse capsule, with a line marked on each side; it contains two cells with numerous seeds.

The common henbane, which grows wild on dunghills, &c. is of a very poisonous quality; it is therefore dangerous to use it internally, though its seeds have been recommended by some in a hæmoptosis and hæmorrhages; but great caution should be used in regard to the quantity prescribed.

HYOTHYROIDES, in anatomy, a muscle of the larynx, which serves to raise it, and constrict the glottis.

HYPÆTHROS, or HYPÆTHRON, in ancient architecture, a kind of temple open at the top.

Vitruvius says, it was an open building or portico, which had no roof or covering, as the temple of Jupiter Olympius, built by Cassius, a Roman architect at Athens.

HYPALLAGE, among grammarians, a species of hyperbaton, consisting in a mutual permutation of one case for another.

HYPATA, in ancient music, an appellation given to the lowest chord of a tetrachord.

HYPECOM, in botany, a genus of plants whose flower consists of four petals: the two exterior petals are broad, trilobated, and obtuse, and are placed opposite. The two interior ones stand alternately with the others: they are lightly divided into three segments, of which the middle one is hollow, compressed and erect. The stamina are four in number. And the fruit is a long, compressed, jointed pod, which is incurved, containing one roundish compressed seed in each joint.

HYPER, *υπερ*, a Greek preposition, frequently

used in composition, where it denotes excess; its literal signification being above, or beyond.

HYPERBATON, in grammar, a figurative construction inverting the natural and proper order of words and sentences. The several species of the hyperbaton are the anastrophe, the hyperon proteron, the hypallage, synchysis, tmesis, parenthesis, and the hyperbaton, strictly so called. See ANASTROPHE, &c.

HYPERBATON, strictly so called, is a long retention of the verb, which completes the sentence.

HYPERBOLA, in geometry, one of the curve lines formed by the section of a cone. See CONIC Sections.

The plane of every hyperbola, is proportioned by this general theorem:

“As the sum of the transverse and any abscissa, multiplied into that abscissa, is to the square of its semi-ordinate; so is the sum of the transverse and any other abscissa, multiplied into the abscissa, to the square of its semi-ordinate.”

That is, if TS (plate LXIII. fig. 5.) be the transverse diameter, and Sa, SA, abscissas, and ba, BA, semi-ordinates: then is  $TS + Sa : TS + SA :: TS + Sa : TS + SA$ . And it will be  $Ta \times Sa : \square ba :: TA \times SA : \square BA$ . That is,  $TS + Sa \times Sa : \square ba :: TS + SA \times SA : \square BA$ .

These proportions are the common property of every hyperbola, and differ only from those of the ellipsis in the signs + and —. See ELLIPSIS.

That is, if we suppose TS (fig. 6.) the transverse diameter, common to both sections, viz. both the ellipsis and hyperbola.

Then in the ellipsis it will be  $TS - Sa \times Sa : \square ab :: TS - SA \times SA : \square AB$ . And in the hyperbola it is  $TS + Sa \times Sa : \square ab :: TS + SA \times SA : \square AB$  as above.

And therefore all that is further required in the hyperbola may be found as in the ellipsis, due regard being had to the changing of the signs.

To find the latus rectum or right parameter of any hyperbola.

From the last proportion, take any of the antecedents and its consequent, viz. either  $Ta \times Sa : \square ab$ . Or,  $TA \times SA : \square AB$ . To them bring in the transverse TS, for a third term, and by those three find a fourth proportional, as in the ellipsis, and that will be the latus rectum.

To find the focus of any hyperbola.

The focus being that point in the hyperbola's axis, through which the latus rectum must pass, as in the ellipsis and parabola, it may be found by this theorem:

“To the rectangle made of half the transverse into half the latus rectum, add the square of half the transverse; the square root of that sum will be the distance of the focus, from the center of the hyperbola.”

To

To describe an hyperbola in plano.

In order to the easy describing of an hyperbola in plano, it will be convenient to premise the following proposition, which differs from that of the ellipsis only in the signs.

*Prop.* If from the focus of any hyperbola there be drawn two right-lines, so as to meet each other in any point of the hyperbola's curve; the difference of those lines (in the ellipsis it is their sum) will be equal to the transverse diameter.

That is, if  $F$  (*fig. 7.*) be the focus, and it be made  $Cf = CF$ ; then the point  $f$  is said to be a focus out of the section (or rather of the opposite section) and it will be  $fB - FB = TS$ .

If this proposition be truly understood, it must needs be easy to conceive how to describe the curve of any hyperbola very readily by points, when the transverse diameter and the focus are given, or any other data by which they may be found, as in the precedent rules.

Thus: — Draw any straight line at pleasure, in it set off the length of the given transverse  $TS$  (*fig. 8.*) and from its extreme points or limits, viz.  $T, S$ , set off  $Tf = SF$ , the distance of the given focus, viz. the point  $f$ , without, and  $F$  within the section as before; that done, upon the point  $f$ , as a center, with any assumed radius greater than  $TS$ , describe an arch of a circle; then from that radius take the transverse  $TS$ , making their difference a second radius, with which, upon the point  $F$ , within the section, describe another arch to cut or cross the first arch as at  $B$ . Then will that point  $B$  be in the curve of the hyperbola, by the last proposition. And therefore it is plain, that, proceeding on in this manner, you may find as many points as may be thought convenient, which being all joined together with an even hand will form the hyperbola required.

There are several other ways of delineating an hyperbola in plano; one way is by finding a competent number of ordinates, but none more easy and expeditious than this mechanical way: we shall therefore, for brevity's sake, pass over the rest, and leave them to the learner's practice, as being easily deduced from what has been already said.

From the comparisons which have been all along made between the hyperbola and the ellipsis, it will be easy to perceive the coherence that is between those two figures. But for the better understanding of what is meant by the center and asymptote of an hyperbola, consider *fig. 9.* where it is evident that the opposite hyperbolas will always be alike, because they will always have the same transverse diameter common to both, &c. Also that the middle point, or common center of the ellipsis, is the common center to all the four conjugal hyperbolas.

And the two diagonals of the right-angled parallelogram which circumscribes the ellipsis (or is

inscribed to the four hyperbolas) being continued, will be such asymptotes to those hyperbolas.

**HYPERBOLÆON**, in ancient music, the upper or last tetrachord or fourth.

**HYPERBOLE**, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged, or diminished. See the article **EXAGGERATION**.

The word is Greek, *υπερβολη*, *superlatio*, formed of the verb *υπερβαλλον*, *exsuperare*, to exceed, surpass by far.

The character of an hyperbole is to exaggerate or extenuate the idea of the things spoken of beyond the bounds of truth, or even probability. As, he ran swifter than the wind; he went slower than a tortoise, &c. Hyperboles, says Seneca, lye without deceiving; they lead the mind to truth by fictions; they convey the sentiment intended, though by expressing it in terms which render it incredible. The hyperbole promises too much, in order to make you conceive enough.

Aristotle observes, that hyperboles are the favourite figures of young authors, who love excess and exaggeration; but that philosophers should not use them without a great deal of reserve. The pitch to which an hyperbole may be carried, is a point of great delicacy. To carry it too far, is to destroy it: it is of the nature of a bowstring, which by immoderate tension, slackens; and frequently has an effect quite contrary to that intended.

Those hyperboles are best, which are latent, and are not taken for hyperboles. For this reason, they should scarce ever be used but in a passion, and in the middle of some important incident: such is the hyperbole of Herodotus, speaking of the Lacedæmonians, who fought at Thermopylæ: "They defended themselves for some time with the arms that were left them, and at last with their hands and teeth; till the Barbarians, continually shooting, buried them, as it were, with their arrows."

Now what likelihood is there, that naked men should defend themselves with their hands and teeth against armed men; and that so many persons should be buried under their enemies arrows? Yet does there appear some probability in the thing, by reason it is not sought for the sake of the figure, but the hyperbole seems to arise out of the subject itself. Of the like kind is that passage in a comic poet mentioned by Longinus; "He had lands in the country no longer than a Lacedæmonian epistle."

**HYPERBOLICAL Cylindroid**, in geometry, a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions, N<sup>o</sup>. 48.

There are two opposite hyperbolas joined by the transverse axis; and through the center there is a right line drawn at right angles to that axis; then the hyperbolas are supposed to revolve, by which revolution

volution a body will be generated, which he calls an hyperbolical cylindroid; and whose basis, and all sections parallel to them, will be circles. And in N<sup>o</sup>. 53, of the Transactions, he applies it to the grinding of hyperbolical glasses; and he says they must be either formed this way, or not at all.

**HYPERBOLIC Space** is the convex area or space contained between the curve of the hyperbola and the external ordinate. If  $CL = b$  (plate LXIII. fig. 10.)  $LQ = x$ ,  $CF = a$ , and  $QP = y$ ; then by the nature of the hyperbola  $aa = by + xy$  and  $y = \frac{aa}{b+x}$ , whence  $y \dot{x} = \frac{aa \dot{x}}{b+x}$ ; wherein, if  $a = b$ ,

we shall have  $\frac{a \dot{x}}{a+x}$  for the fluxion of the indefinite

area LQPF, whose fluent  $x - \frac{x^2}{2a^2} + \frac{x^3}{3a^3} - \frac{x^4}{4a^4}$  &c. will when  $a = 1$  become  $x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \frac{1}{5}x^5$ , &c. for the area required.

Any hyperbolical space GEHG (fig. 11.) is to any other hyperbolic figure of the same height gEhg (whose latus rectum and transverse diameter, as in the circle, are equal, and also both equal to DE the transverse diameter of the former space) as the conjugate axis AB is to the transverse axis DE. The area of any asymptotical hyperbolic space DEVB (fig. 12.) may be found by means of the logarithms. Take the differences of the logarithms of the numbers expressing the ratio of DE to BV, and find the logarithm of that difference, to which add the constant logarithm 0,3622156887; and the sum will be the logarithm of a number expressing the space EDVB, in such parts as the oblong CD is 10000000000.

**HYPERBOLIC Conoid**, is a solid generated by the entire rotation of the hyperbolic space FAG (fig. 13.) about the part AF of the transverse axis.

If AC be the semi-transverse axis, it will be as  $2AC + AF$  is to  $3AC + AF$ , so is the cone whose base is the circle described by FG, and altitude AF, to the conoid described as before. To prove this, let  $AC = a$ ,  $AF = x$ ,  $FG = y$ , the latus rectum  $= b$ , and  $.7854 = p$ ; then  $y^2 = bx + \frac{bxx}{2a}$ ; therefore  $\frac{4pbx^2}{2}$

$+ \frac{2pbx^3}{3a}$  will express the solidity of the conoid, and  $\frac{4pbx^2}{3} + \frac{2pbx^3}{3a}$  that of a cone, whose base is the circle described by FG and altitude AF; but these are manifestly in the proportion of  $3a + x$  to  $2a + x$ , or of  $3AC + AF$  to  $2AC + AF$ .

**HYPERBOLICUM Acutum**, is a solid made by the revolution of the infinite area of the space contained between the curve and the asymptote, in the Apollonian hyperbola, turning round that asymptote. This produces a solid, or body, infinitely long; and yet, as Torricellius plainly demonstrates (who gave it this name) it is equal to a finite magnitude.

**HYPERBOLIC Spindle**. See *Hyperbolic SPINDLE*.

**HYPERBOLIFORM Figures**, are such curves as approach, in their properties, to the nature of the hyperbola, called also hyperboloides.

**HYPERCATALECTIC**, in the Greek and Latin poetry, is applied to a verse, which has one or two syllables too much, or beyond the regular and just measure: as,

*Musæ sorores sunt Minervæ.* Also,

*Musæ sorores Palladis lugent.*

The Greek and Latin verses are distinguished, with respect to their measure, into four kinds, acatalectic, catalectic, brachycatalectic, and hypercatalectic. See *ACATALECTIC*, &c.

The hypercatalectic is also called the hypermeter.

**HYPERDULIA**, in the church of Rome, a species of worship paid to the Holy Virgin; being greater than the dulia, or worship paid to the saints, but less than the latria, or supreme worship paid to the Deity. See *ADORATION* and *WORSHIP*.

**HYPERICUM**, St. John's-wort, in botany, a genus of plants, the flower of which consists of five oblong, obtuse, spreading petals: the stamina are composed of a great number of capillary filaments, coalescing at their base in three or five distinct bodies, and topped with small antheræ: the fruit is a roundish capsule, with two, three, or five cells, containing a great number of small seeds.

The common St. John's-wort, which grows in many parts of England, has a woody perennial fibrous root; from which arises several round stalks dividing into many branches; these are furnished at each joint with two small oblong leaves placed opposite, without pedicles: the flowers grow on the extremities of the branches in numbers together, of a bright yellow colour, and come out in June.

The leaves and flowers of this species are used in medicine, and have been recommended of peculiar efficacy, in hysterical, hypochondriacal, and melancholic disorders, and alienations of mind; from its supposed virtue in which cases, it received the name of *fuga demonum*. It promises to be of some use as a mild detergent and corroborant, discovering to the senses a resinous, bitterish, balsamic impregnation.

**HYPERMETER**, in the ancient poetry, the same with hypercatalectic. See the article *HYPERCATALECTIC*.

**HYPERSARCOSIS**, in medicine and surgery, an excess of flesh, or rather a fleshy excrecence, such as those generally arising upon the lips of wounds, &c. See *WOUND* and *EXCRESCENCE*.

**HYPERTHYRON**, in the ancient architecture, a sort of table used after the manner of a frieze, over the jambs of Doric doors and gates, and the lentils of windows. It lies immediately under the corona, and our workmen usually call it the king-piece.

**HYPHEN**, an accent, or character, in grammar, implying that two words are to be joined, or connected into one compound word, and marked thus -, as pre-established, five-leaved, &c.

Hypkens also serve to connect the syllables of such words as are divided by the end of the line.

**HYPNOTIC**, in the materia medica, such medicines as any way produce sleep, whether called narcotics, hypnotics, opiates, or soporifics.

Authors are of various opinions in regard to the manner wherein hypnotics operate. See the article **NARCOTICS**.

**HYPNUM**, in botany, a genus of mosses consisting of stalks and leaves, and producing membranaceous capsules; these capsules stand on pedicles, which grow on the alæ of the leaves, and have at their base a kind of squamous covering, formed of a matter quite different from the leaves of the plant; the squamous involucre at the base of the pedicle, is called by Dillenius *perichætium*, and is the greater characteristic of the hypna, no mosses of any other genus having it in this form.

**HYPOCAUSTUM**, among the Greeks and Romans, a subterraneous place, wherein was a furnace, to heat the baths. See **BATHS**.

Another kind of hypocaustum was a kind of kiln, to heat their winter parlours.

Among the moderns, it is that place where the fire is kept, that warms a stove or hot-house.

**HYPOCHOERIS**, in botany, a genus of plants whose flowers are compound, imbricated, and uniform, each consisting of numerous hermaphrodite corollulæ, that are all equal: the partial flower is monopetalous, ligulated, linear, truncated, and divided into five segments; there is no pericarpium; the cup is connivent and globose-acuminated; the seed is single, oblong, and ending in a subulated pedicle, covered with down.

**HYPOCHONDRIA**, in anatomy, that part of the body on both sides, which lies under the spurious ribs, and is extended to the ilia; comprehending not only the muscles, but the internal viscera.

**HYPOCHONDRIAC Affection, Passion, or Disease, Morbus Hypochondriacus**, vulgarly called the spleen, vapours, &c. in medicine, a disorder that principally exerts its tyranny under the ensiform cartilage and spurious ribs, in the region of the hypochondria.

**HYPOCISTIS**, in pharmacy, an inspissated juice, much resembling the true Egyptian acacia. We meet with it in moderately large flat masses. It is considerably hard and heavy, of a fine shining black colour, like that of liquorice juice, when fresh broken, and of a duskier black on the surface. It is brought to us from the Levant, and from some parts of Europe. The French make a good deal of it from the plants of their own growth, and sometimes supply other places with it.

Hypocistis is an astringent, and that of consider-

able power; it is good against diarrhoeas and hæmorrhages of all kinds, and may be used in repellent gargarisms in the manner of the acacia; but is very rarely met with genuine in our shops; the German acacia being usually sold under its name.

**HYPOGASTRIC**, an appellation given to the internal branch of the iliac artery. See the articles **ARTERY** and **ILIAC**.

**HYPOGASTRIC VEINS**, arise on each side from the iliacs, and send out branches to the rectum. See the article **VEIN**.

**HYPOGASTRIUM**, in anatomy, the lower part of the abdomen. See **ABDOMEN**.

**HYPOMOCHLION**, in mechanics, the same with fulcrum. See **FULCRUM**.

**HYPOPYON**, in medicine, a collection of purulent matter, immediately under the cornea, near the aqueous humour.

**HYPORCHEMA**, in the Greek poetry, a poem, consisting of divers kinds of verse, and of different lengths; but always full of short, or pyrrhic feet.

**HYPOSTATIS**, among divines, signifies a person, or substance; chiefly used in speaking of the persons of the Trinity. See the article **TRINITY**.

**HYPOSTASIS**, in medicine, denotes the sediment of urine.

**HYPOTHECA**, in the civil law, the same with mortgage in the common law. See the article **MORTGAGE**.

**HYPOTHENAR**, in anatomy, the abductor muscle of the little finger. See the article **ABDUCTOR**.

**HYPOTHENUSE**, or **HYPOTENUSE**, in geometry, the longest side of a right-angled triangle, which subtends the right-angle. Thus, in the right-angled triangle ABC (plate LXIII. fig. 14.) AC is the hypotenuse.

The word is Greek, and derived from *υπο*, under, and *τενω*, to extend.

The 47th prop. of Euclid's first book demonstrates, that in every rectilinear right-angled triangle, the square of the hypotenuse is equal to the squares of both the other sides. It is particularly called the Pythagorean problem, from its invention by Pythagoras, who is said to have sacrificed a whole hecatomb to the muses, in gratitude for their assisting him in the discovery.

**HYPOTHESIS**, in logic, a proposition, or principle, which is taken for granted, in order to draw conclusions therefrom, for the proof of some point in question.

The word is Greek, and compounded of *υπο*, under, and *θεσις*, a thesis, or position, which is derived from *τιθημι*, to place, or put.

**HYPOTHESIS**, in physics, &c. an imaginary system laid down to account for some phenomenon of nature.

Whatever is not derived from phenomena, says Sir

Sir Isaac Newton, is an hypothesis; and no hypotheses of any kind are to be admitted in experimental philosophy.

**HYPOTHESIS**, in astronomy, is more particularly applied to the several systems of the heavens, as different astronomers have supposed the arrangement and motion of the heavenly bodies. The principal of these are the Ptolemaic, Copernican, and Tychoinic systems.

**HYPOTRACHELION**, in architecture, denotes a little frieze in the Tuscan and Doric capitals, between the astragal and annulets, called likewise colerin, gorgerin, &c. By some it is applied to the neck of any column, or that part of the capital below the astragal.

**HYPOTYPOSIS**, in rhetoric, signifies a lively description.

**HYPOZOMA**, in anatomy, a membrane that separates two cavities: such is the diaphragm.

**HYPLOIDES**, in anatomy, the same with os hyoides. See the article **HYOIDES**.

**HYSSOP**, *Hyssopus*, in botany, a genus of plants, the flower of which is monopetalous and ringent, with a narrow cylindrical tube; the upper lip erect, roundish, and emarginated; the lower one divided into three short segments, the middle one of which is hollow and cordated: it hath no pericarpium; but the seeds, which are oval and four in number, are placed in the bottom of the cup.

The common hyssop hath brittle branchy stalks, which are furnished with small lanceolated leaves, placed opposite, in pairs, of a darkish green colour. The flowers come out in July and August, and are of a blue colour, growing in spikes: the whole plant is perennial, and cultivated in gardens.

Hyssop has an acrid taste, and a strong aromatic smell; it strengthens the stomach, helps digestion, and, by its power of attenuating the viscous matter from the lungs, promotes expectoration, and is therefore good in moist asthmas. Its good effects in the stomach are of the same kind, depending on its attenuating and absterging the viscous phlegm lodged there, which impedes the discharge of its proper function. It is also good in diseases of the head. It is best taken in infusion, in the manner of tea, not made so strong as to be disagreeable to the palate, and often repeated. It is one of those few simples, of which there is a distilled water made that is good for any thing; there comes over with it so much of a warm essential oil, as not only prevents it from mothering and stinking, which most simple waters are subject to, but also makes it a good pec-

toral, and efficacious to all those purposes which the herb is given for in any other form.

Externally, hyssop is greatly recommended in bruises; the blackness settling under the eyes from blows, is carried off very readily by a cataplasm of the leaves, or only a little bundle of them sewed up in a linen rag, and applied to the part: and Ray gives us an account from Mr. Boyle, of a violent contusion of the thigh, from the kick of a horse, very happily cured by this herb, boiled as a cataplasm; he tells us, the violent pain was almost instantly removed, and the very mark and blackness taken off in a few hours.

**HYSTERICAL Disease**, **HYSTERIC Affection**, or *Passion*, in medicine, a disease in women, likewise called a suffocation of the uterus, or fits of the mother.

There is no disease so vexatious to women as that called hysterical; and although it may not be attended with any great danger, yet it is frequently very terrifying: and it also sometimes deprives them of their senses as effectually, as if they had been seized with an epileptic fit.

When a woman has fallen into an hysterical fit, blood-letting will be of use, if she has strength to bear it; if not, cupping-glasses are to be applied to her groins or hips: but if she continues long in it, put the snuff of a candle, or some other thing of a foetid smell, to her nostrils, in order to rouse her. In the mean time, her thighs and legs ought to be rubbed.

When she is recovered from the fit, proper means must be used to prevent a relapse. If she be liable to obstructions, and not regular, the menstrual discharges are to be promoted. The strong-smelling gums and steel medicines are very serviceable, and it is very beneficial to use exercise. But the disturbances of the mind generally require proper remedies. *Mead.*

**HYSTERICON PROTERON**, in grammar and rhetoric, a species of the hyperbaton, wherein the proper order of construction is so inverted, as that the part of any sentence which should naturally come first is placed last, as in this of Terence, *Valet & vivit, for Vivit & valet.*

**HYSTEROTOMIA**, *υστεροτομία*, in anatomy, an anatomical dissection of the uterus or womb. See the article **UTERUS**.

**HYSTEROTOMOTOCY**, *υστεροτομοτομία*, among chirurgical writers, the same with the Cæsarian section. See **CÆSARIAN Section**.

# I.

## J A C

**I** Is the third vowel and ninth letter of the English alphabet: it is also a consonant, and accordingly has two forms. When a consonant, it is lengthened downwards, thus *J*, and pronounced not much unlike the soft *G* before *e*, as in *gesture*.

The letter *I* was derived from the old Hebrew *Jod*, and is sounded by throwing the breath suddenly against the palate with a small hollowing of the tongue, and the same opening of the lips and teeth nearly as in pronouncing *A* and *E*.

The Greeks had no *J* consonant, and therefore made use of the *I* vowel instead of it, as *ΙΗΣΟΥΣ*. The English and French have two kinds of *J* consonants; the first has a snuffing kind of sound, and serves to modify that of the following vowels, as in *Few*, *jolly*, &c. The latter is pronounced like the Hebrew *Jod*, which is sounded as the consonant *y*, as we find it still among the Germans, &c. Of this we have some instances in words which are indifferently written with a *y* or *i* before a vowel, as *voiage*, *voyage*, &c.

*J*, in abbreviations and cyphers, stands for *Jesus*.

*I* was used by the ancients as a numeral, denoting 100, according to this verse:

*I. c. Compar erit, et centum significabit.*

The Greek *Iota*, and the Hebrew *Jod*, stand but for ten.

**JACENT**, a term applied by Helmont to nature, when a disease is risen to a head, and the morbid matter strives to suppress the vital flame.

**JACK**, in mechanics, a portable machine for raising great weights.

In order to explain the operation of this machine, we have given perspective views of its several parts on plate LXIII. *fig. 15*, 16, 17, 18, where *fig. 15* is the whole machine; *fig. 16*, shews the rack, and the pinion which carries it; *fig. 17*, displays the whole machinery; and *fig. 18*, the rack, separately. The same letters refer to the same parts in all the four figures.

*A*, is a strong case of wood, firmly bound with iron.

## J A C

*B*, the open part of the case in which the rack moves.

*C*, the bottom claw of the jack, intended for raising weights very near the ground.

*D*, the rack, separated from the other parts of the machinery.

*E*, the upper claw, or fork, of the jack.

*F*, a pinion of four leaves, that moves the rack *D*.

*G*, the winch or crank of the handle.

*H*, a hook to prevent the weight, when raised to a sufficient height, from falling down again, by putting the curved part of the hook round the handle.

*I*, a large wheel, with sixteen teeth.

*K*, a pinion of four leaves, that moves the large wheel *I*.

The power of this machine is very easily calculated in the following manner:

Suppose the winch or crank *G*, to be four times as long as the radius of the pinion *K*, then will the power of the machine in this part be as 4 to 1. But the pinion *K* has only four leaves, and the wheel *I* sixteen teeth; therefore the power of the machine in this part is also as 4 to 1. Consequently,  $4 \times 4 = 16$ , is the power of both these parts conjointly. And as the wheel *I* has sixteen teeth, and the pinion *T*, that moves round the rack, only four leaves, the power of the machine in this part is also as 4 to one. Consequently the whole power of the machine is as 64 to 1: for  $4 \times 4 \times 4 = 64$ . If therefore we suppose a man can work at the handle with a force of thirty pounds, he will be able to raise a weight of one thousand nine hundred and twenty pounds, supposing the machine to have no friction.

**Kitchen JACK**, a compound engine, where the weight is the power applied to overcome the friction of the parts, and the weight with which the spit is charged; and a steady and uniform motion is obtained by means of the fly. See the article **FLY**.

**Smook JACK**. See **SMOAK-JACK**.

**JACK-DAW**, in ornithology, a species of corvus

# J A L

**rus**, with a black and grey head, a brownish black body, and the wings and tail black.

It is one of the smallest of the crow-kind, but an erect and well-shaped bird.

**JACKALL**, in zoology, an animal of the dog-kind, with a slender snout.

It is a very beautiful creature, and so like a dog, as to be mistaken at first sight for some mongrel breed of that animal.

Its size is that of a small hound; and, in the East, where it is a native, there are vast packs of them, often more than two hundred in a company, which hunt animals they would never dare to attack single. It is not impossible that lions and other beasts of prey may be alarmed by the cries of these animals in their chase, and fall in and rob them of their prey; but the general opinion of their attendance on the lion, is fabulous.

**JACOBINE**, or **JACK**, in ornithology, a very small sort of pigeon, with a range of feathers inverted quite over the hinder part of the head; bearing some resemblance to a friar's hood, whence the name.

**JACOBINE MONKS**, the same with the Dominicans. See **DOMINICANS**.

**JACOBITES**, a term of reproach bestowed on the persons, who, vindicating the doctrines of passive obedience and non-resistance with respect to the arbitrary proceedings of princes, disallow of the late Revolution, and assert the supposed rights, and adhere to the interests of the late abdicated king James and his family.

**JACOBITES**, in church-history, a sect of Christians in Syria and Mesopotamia; so called either from Jacob, a Syrian, who lived in the reign of the emperor Mauricius; or from one Jacob, a monk, who flourished in the year 550.

**JACOB'S-STAFF**, a mathematical instrument, otherwise called fore-staff. See **FORE-STAFF**.

**JADE-STONE**, a name given to a hard greyish green species of jasper, of which the Turks generally make the handles of the sabres of great people. See the article **JASPER**.

**JALAP**, in botany, a plant with thick, fleshy, radish-like roots; jointed stalks and branches; acuminate somewhat oval leaves set in pairs; and elegant, numerous, monopetalous, funnel shaped flowers, purple, yellow, white, or diversly variegated, standing in double cups, of which the innermost incloses the flower and the outer surrounds its basis: each flower is followed by a wrinkled, roundish, pentagonal, umbilicated fruit, about the size of a pepper-corn, including a white kernel. It is perennial, a native of the East-Indies, and cultivated in our gardens. Whether the roots produced here are equivalent in virtue to those which are brought from abroad, has not, Dr. Lewis observes, been yet experienced.

# J A M

The officinal jalap roots come from the province of Xalapa in New Spain; in thin transverse slices, solid, hard, weighty, of a dark greyish colour on the outside or cortical part, internally of a dark greyish, with several black circular striæ: the hardest, darkest coloured, and those which have the most of these resinous veins, are the best.

This root has scarcely any smell, and very little taste upon the tongue: swallowed, it affects the throat with a slight kind of pungency and heat. Taken in doses of a scruple or half a dram, it proves an effectual, and in general a safe purgative; very rarely occasioning any severe gripes or nausea, which too frequently accompany the other strong cathartics. Some have prohibited the use of this cathartic to children; apparently on no very good foundation. Young children, from the laxity of their solids, and the soft lubricating quality of their food, generally bear these kinds of medicines better than adults; and adults of a spongy, lax, or weak habit, better than the rigid or robust. Few, if any, of the strong resinous purgatives are in either case more innocent than jalap.

**JAMAICA-PEPPER**, *Pimenta*, or *Pimenta*, in the materia medica. See **PIMENTA**.

**JAMAICA-WOOD**, a name sometimes given to brazil. See the article **BRAZIL**.

**JAMB**, or **JAUMB**, among carpenters, an appellation given to door-posts, as also to the upright posts at the sides of window-frames; and among bricklayers, it denotes the upright sides of chimnies, from the hearth to the mantle-tree.

**IAMBIC VERSES**, are verses in the Greek and Latin poetry, which are so called, as they wholly, or, for the most part, consist of an iambus or iambic foot.

**IAMBUS**, in ancient poetry, a simple foot, consisting of a short and a long syllable, as *pis*. See **FOOT**.

**JAMES**, or *Knights of St. JAMES*, a military order in Spain, first instituted about the year 1170, by Ferdinand II. king of Leon and Galicia. The greatest dignity belonging to this order is grand master, which has been united to the crown of Spain. The knights are obliged to make proof of their descent from families that have been noble for four generations, on both sides: they must also make it appear that their said ancestors have neither been Jews, Saracens, nor heretics; nor have ever been called into question by the inquisition. The novices are obliged to serve six months in the galleys, and to live a month in a monastery; they observe the rule of St. Austin, making no vows but of poverty, obedience, and conjugal fidelity.

**St. JAMES'S-DAY**, a festival of the Christian church, observed on the 25th of July, in memory of St. James the greater, son of Zebedee.

*Epistle of St. JAMES*, a canonical book of the New

New Testament, being the first of the catholic or general epistles; which are so called, as not being written to one but to several Christian churches.

**JANIZARIES**, an order of the Turkish infantry, reputed the grand signor's guards, and the main strength of the Ottoman army.

**JANSENISTS**, in church-history, a sect of the Roman-catholics in France, who follow the opinions of Jansenius, bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, in relation to grace and predestination.

**JANUARY**, the first month in the year, according to the present computation. It was introduced by Numa into the calendar, and placed at the winter solstice, where March was before, which Romulus had placed at the vernal equinox.

The word is derived from Janus, to whom the Romans, on the first of this month, offered solemn sacrifices.

**JAPAN EARTH**, in the materia medica. See the article *TERRA Japonica*.

**JAPANNING**, the art of varnishing and drawing figures on wood, in the same manner as is done by the natives of Japan in the East-Indies.

**JASHER**, a book mentioned in scripture, and said by some to be lost; but some of the most celebrated Hebrew doctors say they have found it; telling us, that it is the book of Genesis, wherein are contained the acts of Abraham, Isaac, Jacob, and the other patriarchs, who were, by way of excellence, called Jasherim, the Just: but that man must be easily satisfied, who can acquiesce with this interpretation. Dr. Lightfoot thinks the book of Jasher is the same with the book of the Wars of God; but there is little foundation for it. This book, according to Grotius, was a triumphal poem; but Josephus seems to bid fairest for the truth, who says, that by this book are to be understood certain records kept in some place on purpose, and afterwards in the temple, giving an account of what happened among the Hebrews from year to year, and particularly the prodigy of the sun's standing still, and directions and laws about the use of the bow; that is, the setting up of archery, and maintaining military exercises. If it be enquired why the title given to these Hebrew annals was the book of Jasher (that is, the upright) this may be given as a reason, Because it was by all persons reckoned as a very just and authentic account of all those events and occurrences which it recorded: it was composed with great uprightness and truth; thence it went commonly by the name of Jasher's book, or chronicle. It was not the work of any inspired person, but was of the nature of common civil annals; and, consequently, we cannot infer from hence, that any book properly belonging to the Holy Scripture, that is, that was written by the inspiration of the Holy Ghost, is at this day missing.

**JASMINUM**, the jasmine, or jessamine-tree, in

botany, a genus of plants, the leaves of which are in many species pinnated; the cup of the flower consists of one leaf, but is divided at the top into five segments; the flower consists of one leaf, is funnel-shaped, and divided into five segments: the flowers are succeeded by berries, which split in the middle, each side, for the most part, containing a separate seed.

The common white jasmine is easily propagated by laying down the tender branches in the spring, which, by the succeeding spring, will be rooted strong enough to be transplanted. They may also be raised by cuttings, which should be planted in autumn in a moist border, where they may have the morning sun: but they must be screened from the violence of the sun in the heat of the day, and frequently watered in dry weather. The cuttings, thus managed, will many of them live, and have roots fit to be removed in the following spring: but this method is seldom practised, the layers always making the best plants.

The two striped sorts should be planted in a warm situation, especially the white striped; for they are much more tender than the plain, and are very subject to be destroyed by great frosts, if they are exposed thereto: it will therefore be proper to preserve a plant of each kind in pots, which may be removed into the green-house in winter, lest, by exposing them to the cold, they should be destroyed, and the variety lost.

**JASPER**, in natural history, a genus of scrup, of a complex irregular structure, of great variety of colours, and emulating the appearance of the finer marbles, or semi-pellucid gems.

**JATROPHA**, casada plant, in botany, a genus producing male and female flowers: the male is monopetalous, and saucer-shaped, with a very short tube; and the limb divided into five segments. The female flower is pentapetalous and rosaceous, placed in the same umbel with the male. The fruit is a roundish trilocular capsule, containing three roundish seeds.

**JAVELIN**, *Hasta*, in antiquity, a sort of spear, five feet and a half long; the shaft of which was of wood, with a steel point.

Every soldier, in the Roman armies, had seven of these, which were very light and slender.

**JAUNDICE**, in medicine, a disease arising from a vitiated state of the blood and humours, by means of an excrementitious bile, from a fault of the bilious ducts, greatly injuring the functions of the whole body, and rendering the skin of a yellow or livid colour.

**JAW**, *Maxilla*, in anatomy. See the article *MAXILLA*.

**IBERIS**, in botany, a genus of plants whose flower consists of four unequal petals, vertically oval, obtuse, and patent, with six stamina.

The fruit is a little pod, erect, roundish, compressed

# ICH

pressed, surrounded by an acute bifid margin on the upper side, and containing two cells, in each of which is inclosed an oval seed.

**IBEX**, in zoology, an animal of the goat-kind, with extremely long nodose horns, which bend backwards, and are of a blackish colour, and annulated on the surface. The body is of a dark dusky colour, and is less in proportion to the height than that of the common goat: it has a great resemblance to the deer-kind; the legs are also perfectly, like those of the deer, straight, elegant, and slender. It is frequent in many parts of Europe, and, notwithstanding its vast horns, runs and leaps with surprising force and agility.

**IBIS**, a bird which was very useful to the Egyptians for destroying serpents, locusts, and caterpillars; and, on that account, had divine honours paid it.

It is all over black, and about the size of the curlew, with the head of a cormorant, and the long neck of a heron.

**ICE**, *Glacies*, in physiology, a solid, transparent, and brittle body, formed of some fluid, particularly water, by means of cold. See **COLD**, **FROST**, and **FREEZING**.

**ICE-HOUSE**, a building contrived to preserve ice for the use of a family in the summer season.

Ice-houses are more generally used in warm countries, than with us, particularly in Italy, where the meanest person, who rents a house, has his vault or cellar for ice.

**ICH DIEN**, the motto of the prince of Wales's arms, signifying, in the High Dutch, *I serve*.

**ICHNEUMON**, in zoology, the name of an animal, of which there have been a multitude of idle and fabulous things asserted. It is a creature of the weasel kind, with a longer and narrower body than a cat, and something approaching both in shape and colour to the badger.

**ICHNEUMON** is also the name of a genus of flies, of the hymenoptera order, with a triple sting at the anus.

**ICHOGRAPHY**, in perspective, the view of any thing cut off by a plane parallel to the horizon, just at the base of it.

Among painters it signifies a description of images, or of ancient statues of marble and copper, of busts and semi-busts, of paintings in fresco, Mosaic works, and ancient pieces of miniature.

**ICHOGRAPHY**, in architecture, a description or draught of the platform or ground-work of a house, or other building. Or it is the geometrical plan or platform of an edifice or house, or the ground-work of an house or building, delineated upon paper, describing the form of the several apartments, rooms, windows, chimnies, &c.

**ICHOGRAPHY**, in fortification, denotes the plan or representation of the length and breadth of

# IDE

a fortress, the distinct parts of which are marked out, either on the ground itself, or on paper.

**ICHOGLANS**, the grand signior's pages, serving the seraglio.

**ICHOR** properly signifies a thin watery humour, like serum; but is sometimes also used for a thicker kind, flowing from ulcers, called likewise sanies.

**ICHTHYOCOLLA**, vulgarly called isinglass, a solid glutinous substance, prepared from a fish of the sturgeon kind caught in the rivers of Russia and Hungary.

**ICHTHYOLOGY**, *ἰχθυολογία*, the science of fishes, or that branch of zoology which treats of fishes. See the article **FISH**.

**ICHTHYOLOGIST**, an author who has written professedly of fishes.

**ICHTHYS**, *ἰχθυς*, in antiquity, a celebrated acrostic of the Erythræan sibyl; the first words of each verse of which were, *Χριστός Θεὸς υἱὸς αἰῶνος*, that is, *Jesus Christus Dei filius servator*; and the initial Greek letters form the word *ἰχθυς*, whence the name.

**ICONOCLASTS**, *εικονοκλαστοί*, in church history, an appellation given to those persons, who, in the eighth century, opposed image-worship; and is still given by the church of Rome, to all Christians who reject the use of images in religious matters. See **IMAGE**.

**ICOSAHEDRON**, a regular solid, terminated by twelve equilateral and equal triangles.

The word is Greek, and compounded of *εικοσι*, twenty, and *εδρα*, a base.

It may be considered as consisting of twenty triangular pyramids, whose vertices meet in the center of a sphere that circumscribes them, and therefore have their heights and bases equal; wherefore the solidity of one of these pyramids multiplied by twenty, the number of bases, gives the solid content of the icosaedron.

**ICOSANDRIA**, the name of the twelfth class in the Linnæan system of botany, comprehending those plants whose flowers are hermaphrodite. The calyx monophyllous and concave, with the corolla fastened by its claws to the inner side of the cup; and containing twenty or more stamina affixed to the cup. The principle characteristic of this class is rather to be taken from the manner of insertion; for though the number of stamina are rarely less than twenty, yet in some species they frequently exceed it.

To this class belong the torch-thistle, almond, plumb, pear, strawberry, myrtle, with several other genera.

**ICTERIC DISEASE**, the same with the jaundice. See **JAUNDICE**.

**IDEA**, the representation or resemblance of something, even though not seen, as conceived by the mind.

# I D E

As to the origin of ideas, the Peripatetics maintain that external objects emit species entirely resembling them, and that these species striking on our senses are by them transmitted to the understanding; that being material, they are rendered intelligible by the active intellect, and are at length received by the passive.

Others think that our souls have of themselves the power of producing ideas of things we would think upon, and that they are excited to this by the impressions which objects make our senses, though these impressions are not images of any thing resembling the objects that occasioned them.

Others maintain that the mind, by considering itself and its own perfections, can discover all things that are without. Others, with Des Cartes, hold that our ideas are innate or born along with us.

Malebranche and his followers maintain that God has in himself the ideas of all the beings he has created, and thus he sees all things in considering his own perfections to which they correspond; and that, as he is intimately united to our souls by his presence, our minds perceive things in him which represent created beings; and that thus we come by all our ideas: and yet, says he, though we see all sensible things in God, we have not our sensations in him: for in our perception of any sensible object is included both a sensation and a pure idea. The sensation is a mortification of the soul; and it is God who causes it in us; but the idea joined with the sensation is in God, and it is in him we see it.

The Cartesians distinguish three kinds of ideas; the first innate; such as we have of God, as a being infinitely perfect: secondly, adventitious, which the mind receives in proportion as objects present themselves to our senses: thirdly, factitious, those which the mind forms by assembling and combining the ideas it already had, and these are called complex. But Mr. Locke has made it appear that all our ideas are owing to our senses, and the reflection of our minds upon those ideas which the senses have at first furnished us with; and that the distinction of the Cartesians is mere chimera. See *Locke's Essay on the Human Understanding*.

**IDENTITATE NOMINIS**, in law, a writ that lies where a person is imprisoned instead of another of the same name, commanding the sheriff to enquire whether the prisoner be the person against whom the action was brought, or not; and if not, to discharge him.

**IDENTITY**, or **SAMENESS**, denotes that by which a thing is itself, and not any thing else; in which sense, identity differs from similitude as well as diversity.

**IDES**, *Idus*, in the Roman calendar; eight days in each month are so denominated, commencing in the months of March, May, July, and October, on the fifteenth day, and in the other months on the thirteenth, and reckoned backward, so as in the

# I D Y

four months above specified to terminate on the eighth day, and in the rest on the sixth.

The word is variously derived; it seems most probably to be formed of the Etrurian word *iduo*, for *divido*, to divide; because the ides divided the month into two equal parts.

The ides came between the calends and nones. The fourteenth day of March, May, July, and October, and the twelfth of the other eight months, was *pridie idus*, or the eve of the ides: the thirteenth in the four months, and the eleventh in the other eight, was called 3 idus, or the third of the ides of such months: and so on to the eighth and sixth days, which made the eighth of the ides, 8 idus.

The method of reckoning is still retained in the Roman chancery, and calendar of the breviary.

The ides of May were consecrated to Mercury; those of March were esteemed unhappy after Cæsar's murder on that day: the time after the ides of June was reckoned fortunate for those who entered into matrimony; the ides of August were consecrated to Diana, and observed as a feast day by the slaves. On the ides of September auguries were taken for appointing the magistrates, who formerly entered upon their offices on the ides of May, afterwards on those of March.

**IDIUM**, *Idioma*, either the peculiarities of a language, or the particular dialect of some province, differing in some respects from the language of the nation in general, from which it is derived.

The word is Greek, *ιδιωμα*, signifying the same thing, and derived from *idios*, proper, or one's own.

**IDIOPATHY**, in physic, a disorder peculiar to a certain part of the body, and not arising from any preceding disease; in which sense it is opposed to sympathetic. Thus, an epilepsy is idopathic, when it happens merely through some fault in the brain; and sympathetic, when it is the consequence of some other disorder.

**IDIOSYNCRASY**, among physicians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain disorders, than persons of a different constitution usually are. See the article **TEMPERAMENT**.

**IDIOT**, in the English laws, denotes a natural or fool from his birth.

A person who has understanding enough to measure a yard of cloth, number twenty righty, and tell the days of the week, &c. is not an idiot in the eye of the law.

In other countries, repeating the Lord's prayer saves a man from being reckoned an idiot.

**IDOLATRY**, the adoration paid to idols and false gods, which is due to God alone.

**IDYLLION**, *ειδυλλιον*, in ancient poetry, is only a diminutive of the word *ειδος*, and properly signifies any poem of moderate extent, without considering the

the subject. But as the collection of Theocritus's poems were called *Idyllia*, and the pastoral pieces being by far the best in that collection, the term *idyllion* seems to be now appropriated to pastoral pieces. See the article *PASTORAL POETRY*.

So very different are our modern *idyllions* from those of the ancients, by introducing none but allegorical shepherds, that a literal translation of Theocritus's *idyllions*, however well executed, would be relished only by people of taste, and those too well acquainted with the simplicity and manners of the ancients.

**JEALOUSY**, in general, denotes the fear of a rival; but is more especially understood of the suspicion which married people entertain of each other's fidelity and affection.

*Bitter Waters of JEALOUSY*, in Jewish antiquity, certain consecrated waters, which a woman was obliged to drink, in order to clear herself of the crime of adultery, whereof her jealous husband accused her; the consequence of which draught was, that if innocent she suffered no harm, but if guilty her belly swelled, &c.

**JEARS**, in the marine, a certain double tackle, or complication of pulleys, whereby to raise the principal sail-yards of a ship, particularly those of the main, fore, and mizzen-sails.

**JECUR**, the liver, in anatomy. See the article *LIVER*.

**JEHOVAH**, one of the Scripture names of God, signifying the Being who is self-existent, and gives existence to others. See the article *GOD*.

**JEJUNUM**, in anatomy, the second of the small guts, so called because it is generally found empty. This is owing to the fluidity of the chyle, the greater stimulus of the bile in it, and the abundance of the lacteal vessels with which it is furnished. Its situation is in the region above the navel; it has a great many convoluted glands. Its beginning is where the duodenum ends; and it terminates where these valves are obliterated. Its length is different in various subjects; but is usually between thirteen and sixteen spans.

**JEFOAILE**, or **JEFOAYLE**, in law, a term used for an oversight in pleading, or other proceedings in law.

**JERUSALEM-ARTICHOKE**. See the article *HELIANTHUS*.

**JESUITS**, or the society of Jesus, a most famous religious order in the Romish church, founded by Ignatius Loyola, a native of Guipuscoa in Spain, who in the year 1538, assembled ten of his companions at Rome, principally chosen out of the university of Paris, and made a proposal to them to form a new order; when, after many deliberations, it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth, which was, to go into all countries whither the pope should please to send them, in order to make con-

verts to the Romish church. Two years after, pope Paul III. gave them a bull, by which he approved of this new order, giving them a power to make such statutes as they should judge convenient; on which, Ignatius was created general of the order; which in a short time spread over all the countries of the world, to which Ignatius sent his companions, while he staid at Rome, from whence he governed the whole society.

The entire society is composed of four sorts of members; novices, scholars, spiritual and temporal coadjutors, and professed members. The novices continue so two years, after which they are admitted to make the three simple vows, of chastity, poverty, and obedience, in the presence of their superiors: the scholars add some spiritual exercises to their studies. The principal coadjutors assist the professed members, and also make the three simple vows: the temporal coadjutors, or lay-brothers, take care of the temporal affairs of the society; and the professed members, which compose the body of the society, besides the three simple vows, add a special vow of obedience to the head of the church in every thing relating to missions among idolaters and heretics. They have professed houses for their professed members and coadjutors; colleges, in which the sciences are taught to strangers; and seminaries, in which the young jesuits go through a course of philosophy and theology. They are governed by a general, who has four assistants, and who appoints rectors, superiors of houses, provincials, visitors, and commissaries. The discipline of these houses, and especially of the colleges, was regulated by Ignatius himself.

**JET**, *Gagates*, in natural history, a solid, dry, opaque, inflammable substance, found in large detached masses, of a fine and regular structure, having a grain like that of wood, splitting more easily horizontally than in any other direction, very light, moderately hard, not fusible, but readily inflammable, and burning a long time with a fine greenish flame.

It is of a fine deep black colour, very glossy and shining, except upon its surface, where it has been fouled by accident. When examined by the microscope, it is found to be composed of a number of parallel plates, very thin, and laid closely upon one another. It is not soluble in, nor makes any effervescence with acids. It should be chosen of the deepest black, of a moderate hardness, very light, and such as will split most evenly in an horizontal direction; this being its great characteristic, by which it is distinguished from the cannel-coal, which breaks easy any way.

Jet is of great use to perfumers, and is sometimes prescribed in medicine.

**JET D'EAU**, a French term, frequently also used with us for a fountain that casts up water to a considerable height.

**JET-**

**JETSON, JETSEN, or JETSAM**, in law, is used for any thing thrown out of a ship or vessel that is in danger of being a wreck, and which is driven by the waves on shore. See **FLOTSON**.

**JEWEL**, any precious stone or ornament beset with them. See **DIAMOND, RUBY, &c.**

**JEWEL-BLOCKS**, among sailors, certain pulleys hung to the outer-ends or yard-arms of the top-sail yards: they are used to hoist the studding-sails by. See the article **STUDDING-SAIL**.

**JEWEL-OFFICE**, an office belonging to the crown, that has the charge of fashioning and weighing the king's plate, and delivering it out by warrants from the lord chamberlain.

The principal officer is the master of the jewel-office, who has a salary of four hundred and fifty pounds per annum.

**JEWS**, those who profess obedience to the laws and religion of Moses, before whom every man worshipped God according to the inclination of his own heart.

How far the religious ceremonies of the Jews were copied from those of the Egyptians, among whom they had so long sojourned, or how far they were typical of something future, are questions which we leave to be discussed by divines. But as to the religion of the modern Jews, it is a manifest absurdity; since being without a temple, sacrifices, &c. it cannot be considered as subsisting any longer.

**JEWISH HOURS**, in chronology. See the article **HOURLY**.

**IGNIS FATUUS**, in meteorology, a meteor, otherwise called, Will-with-a-wisp. See the article **WILL-With-a-Wisp**.

**IGNIS GEHENNÆ**, the same with the universal dissolvent, or alkahest. See **ALKAHEST**.

**IGNIS JUDICI**, in our old customs, a purgation by fire. See **ORDEAL**.

**IGNITION**, in chemistry, the heating metals red-hot, without melting them. Lead and tin are too soft to bear ignition, which takes effect only in the harder metals, as gold and silver, but especially iron.

**IGNORAMUS**, in law, a term signifying we are ignorant. This is used when the grand jury impanelled on the inquisition of criminal causes, reject the evidence as too weak to make good the presentment or indictment brought against a person, so as to bring him upon his trial by a petty jury; in which case they indorse this word on the back of the bill of indictment. In consequence of which, all further proceedings against the party accused are stopped, and the supposed offender is delivered without further answer.

**IGNORANCE**, *Ignorantia*, the privation or absence of knowledge. See the article **KNOWLEDGE**.

**IGNORANCE**, in law, is a want of knowledge of the laws, which will not excuse a person from

suffering the penalty inflicted on the breach of them; for every one is obliged, at his peril, to know the laws of the land.

**IGUANA**, in zoology, an American species of lizard, with a long round tail, five toes on each foot, and the crest of the throat and the dorsal surface dentated.

**JIB**, among seamen, the foremost sail of a ship, or that which is extended the furthest before the prow: it is, like all the other stay-sails, of a triangular form, and is hoisted from the jib-boom towards the fore-top-mast head.

**JIB-BOOM**, a certain pole or sloping mast, which is run out on a line with the bowsprit, to bear out the jib to its proper extent: this boom can occasionally be drawn in, which is always the case when they come into a harbour, to prevent breaking amongst the shipping at anchor or passing.

**ILEX**, the holly tree, in botany. See the article **HOLLY**.

**ILEX COCCIGERA**, or holm oak, is of much lower stature than the former sorts, and seldom grows to the height of a tree: this, though a native of the warmest parts of France, yet will endure the cold of our climate in the open air. It may be propagated in the same manner as the former, and deserves a place among other shrubs of low growth for its curiosity, as being the plant on which the kermes are bred.

**ILIAC PASSION**, called also *Volvulus, Miserere Mei*, and *Chordapsus*, in physic, a severe kind of cholick.

This disease, by the Greeks, is a violent inflammation of the intestine, which, unless speedy relief be given, soon terminates in a gangrene, and death.

Wherefore blood must be plentifully drawn with great expedition, not only once, but twice, and generally thrice: then the belly is to be moved; but this is very difficult to be done, because acrid cathartics cause too great an irritation, and are thrown up by vomit: therefore it is to be attempted by stimulating clysters, and gentle cathartics, which are most likely to give mutual assistance to each other's operations. Anodynes too are necessary, but mixed with the purging medicines. Thus a very proper medicine will be a scruple of the cathartic extract, with one grain of the Thebaic extract; and some hours after, two spoonfuls of infusion of senna, with the addition of a fourth part of the tincture of senna, to be taken either every hour, or every two hours, till the patient has had a sufficient number of stools.

If this course prove ineffectual, it will be right to order quicksilver to be swallowed down; which has a two fold use in this case; to wit, by its ponderosity, that of restoring the natural motion of the intestines, which is inverted; and by its slipperiness, that of softening and driving downward the

excrements which stop the passage. Upon these accounts it is to be given in large quantities, to a pound weight at least; and generally requires to be repeated. Nor ought the physician to use any long delay in trying this experiment, for fear of an actual mortification of the inflamed parts, whereby the coats of the intestines are destroyed, and the quicksilver runs into the cavity of the abdomen.

In short, fomentations are of some service, particularly warm flannels soaked in spirits of wine; or what Sydenham prescribes, a live puppy held constantly on the bare belly. But an immersion up to the breast in the warm bath is far more beneficial; and if the pain is not dissipated, it will be proper to apply cupping-glasses, with slight scarifications about the navel.

The same method of cure is to be observed in that severe disease, by the French called *colica pictonum*, and by the English in the American islands, where it is very rife, the dry belly-ach: for it is a pain attended with a fever and inflammation, and most troublesome costiveness. *Mead.*

**ILIACUS MUSCULUS**, in anatomy, a broad thick muscle, lying on the inside of the os ilium. It is fixed by fleshy fibres to the internal labium of the crest of the os ilium, to that of the slope between the two anterior spines, to the insides of these spines, to the superior half of the inside of this bone, and to the adjacent lateral part of the os sacrum. All these fibres, contracting by degrees, run obliquely towards the lower parts of the muscular psoas, uniting with it; and being fixed by a kind of aponeurosis to the outside of its tendon, all the way to the little trochanter.

**ILIAD**, *ίλιάς*, in literary history, the name of an ancient epic poem, the first and finest of those composed by Homer.

As there was no true history before the first Olympiad, it is reasonable to suppose that Homer took the subject of his Iliad from those traditional stories which were handed down from father to son, respecting the Trojan war; adding such other characters, allegories, and circumstances, as were suitable to his design, which was evidently that of displaying to his countrymen (who were Greeks) the mischievous effects of their too frequent dissensions, and the benefits arising from a contrary conduct.

It is to be observed, that at the time Homer wrote this poem, and for some centuries before, the Grecians were divided into as many small independent states as they had large cities: and as their body politic and government were distinct and different, so was too often their interest, whence arose animosities and sometimes wars among themselves; yet as these people had very powerful neighbours, and inveterate enemies, they were often obliged, notwithstanding their own petty quarrels, to conferate themselves together under one general for their mutual safety; and when they were thus united, and had

no contention among them, they were generally victorious, and an over-match even for the Persians; but on the contrary, when by their own feuds and dissensions, their armies were divided and weakened, their enemies prevailed over them, and part of their country was despoiled.

Homer saw this, and knowing that an instructive lesson on the subject, disguised under the allegories of an important action, and delivered in an insinuating pleasing manner, would do more good with such a people than the most powerful oratory and argumentation, he composed his Iliad for their use; the design of which is to shew, that unanimity and concord among princes and governors occasioned the preservation and prosperity of states, and that discord brought on their destruction. This, therefore, is the principal moral of the poem; and this he has exemplified in the anger of Achilles and its consequences, which forms the action and fable of the poem, which is as follows:

Several Grecian princes, independent of each other, are united against the Trojans, to revenge themselves of an insult offered to Menelaus, king of Sparta. They elect Agamemnon, brother to the injured prince, their general, who by an act of violence affronts Achilles, the most valiant of all the confederates; upon which this prince breaks the union, withdraws from the army, and obstinately refuses to fight for the common cause; whereupon there are contentions among the troops, who grow mutinous, and the Trojans taking advantage of the absence of Achilles, and of their disputes and divisions, recover new spirits, destroy a great number of the Greeks, and press them so close, that they are obliged to raise fortifications to secure their fleet, are about to quit the Phrygian coast, and to return home with dishonour. Agamemnon, by the advice of the other princes, solicits a reconciliation with Achilles, but in vain. He continues inexorable, and refuses them aid, even at a time when all their best generals were wounded, their fortifications destroyed, and the fleet set on fire; at last, however, he permits his dearest friend Patroclus to fight for the Greeks in his armour, who is killed by Hector; this draws the fury of Achilles on the Trojans, and Agamemnon and he having both severely suffered for their folly, are made friends: Achilles returning again to the army, kills Hector with his own hand, and the Trojans are vanquished: so that in this poem, which does not extend to the destruction of Troy, but ends with the death of Hector, because that puts an end to the anger of Achilles, and the action is complete, the poet has fully inculcated his intended moral, by shewing the terrible effects which ensued from a division among their princes, and the good effects which attended their union and friendship.

To excite curiosity, and raise our admiration to the highest pitch, he has inserted many things that  
are

are wonderful, and out of nature; but they are generally introduced with the pomp of celestial machinery, and by favour of the gods and goddesses, in order that they may appear probable, and obtain belief. We are also to observe, that as valour was a darling passion among the Greeks, he has magnified their deeds, that they might read his works with the greater pleasure, and that the moral might be more effectually fixed upon the mind.

Homer had such a comprehensive genius, such a fertile fancy, and was so well acquainted with persons and things, and especially with the passions and humours of mankind, that the ancients esteemed him as the great high-priest of nature, who was admitted into her inmost choir, and instructed in her most solemn mysteries. The characters of his persons, though very numerous, are drawn with so much judgment, with such a surprising variety, and so distinguished by their manners and sentiments, that every one has something peculiar to himself, by which he is discovered even in his speeches from all the rest.

The distinctions he has observed in the different degrees of virtues and vices are extremely exact; and the single quality of courage, which he has given to most of his heroes, is so wonderfully diversified, that it appears different in each. Thus in a fine piece of painting, where some particular passion is represented, every face appears affected; but the attitude and turn of the features shew, that each is affected in a different manner, or in a different degree.

If we may credit Strabo the historian and geographer, Homer has been as exact in his description of countries and cities, as in that of his persons: but what more particularly recommends him to readers of taste and genius, is his amazing imagination, his fertility of invention, which is indeed the very fountain of all poetry, and discovers itself in a miraculous manner, not only in his fable, allegories, machinery, and characters, but even in his descriptions, images, and similes, which are even bold and animated. Every thing is alive in Homer. There is little of narration; for the persons appear, as it were, before you, and speak for themselves. He has, as Aristotle observes, found out living words, and, by daring tropes and figures, conveys his sentiments in an unusual and surprising manner.

In him a weapon thirsts to drink the blood of an enemy; an arrow is impatient to be on the wing; his heroes are clothed with courage and fortitude. Even his epithets discover his strength of invention, and in many cases answer the end of elaborate descriptions, especially when compounded in his manner, as the Cloud-compelling Thunderer, the Fardarting Phœbus, &c. Nor is the force of his invention much less obvious in the structure of his verse, and the dignity and harmony of his numbers, which flow from Homer with so much ease, says

Mr. Pope, that one would "imagine he had no other care than to transcribe as fast as the muses dictated; and at the same time with so much force and inspiring vigour, that they awaken and raise us like the sound of a trumpet. They roll along as a plentiful river, always in motion, and always full; while we are borne away by a tide of verse, the most rapid, and yet the most smooth imaginable.

"Thus on whatever side we contemplate Homer, what principally strikes us is his invention. It is that which forms the character of each part of his work; and accordingly we find it to have made his fable more extensive and copious than any other, his manners more lively and strongly marked, his speeches more affecting and transported, his sentiments more warm and sublime, his images and descriptions more full and animated, his expression more raised and daring, and his numbers more rapid and various.

"What he writes is of the most animated nature imaginable; every thing moves, every thing lives, and is put in action. If a council be called, or a battle fought, you are not coldly informed of what was said or done as from a third person; the reader is hurried out of himself by the force of the poet's imagination, and turns in one place to a hearer, in another to a spectator. The course of his verses resembles that of the army he describes. They pour along like a fire that sweeps the whole earth before it. It is, however, remarkable, that his fancy, which is every where vigorous, is not discovered immediately at the beginning of his poem in its fullest splendor. It grows, in the progress, both upon himself and others, and becomes on fire like a chariot wheel, by its own rapidity. Exact disposition, just thought, correct elocution, polished numbers, may have been found in a thousand; but this poetical fire, this *vivida vis animi*, in a very few. Even in works, where all those are imperfect or neglected, this can overpower criticism, and makes us admire even while we disapprove. Nay, where this appears, tho' attended with absurdities, it brightens all the rubbish about it, till we see nothing but its own splendor. This fire is discerned in Virgil, but discerned as in a glass, reflected from Homer, more shining than fierce, but every where equal and constant. In Lucan and Statius, it bursts out in sudden, short, and interrupted flashes. In Milton, it glows like a furnace, kept up to an uncommon ardour by the force of art. In Shakespeare, it strikes before we are aware, like an accidental fire from heaven: but in Homer, and in him only, it burns every where clearly, and every where irresistibly.

"This strong and ruling faculty was like a powerful star, which, in the violence of its course, drew all things within its vortex. It seemed not enough to have taken in the whole circle of arts, and the whole compass of nature; all the inward passions and

and affections of mankind, to supply his characters; and all the outward forms and images of things for his descriptions; but, wanting yet an ampler sphere to expatiate in, he opened a new and boundless walk for his imagination, and created a world for himself in the invention of fable; for that which Aristotle calls the soul of poetry, was first breathed into it by Homer."

**ILIUM**, in anatomy, the third and last of the small guts, is situated principally below the navel, near the ossa ilii; whence its name. Its length is various: sometimes not more than fifteen, sometimes twenty spans or more. Its beginning is where the valves of the jejunum cease to be conspicuous, and its end is where the larger intestines begin; in which place it is, in a very singular manner, inserted into the left side of the colon. It has no other valves except that great one at the end, which is called, by many, *valvula coli Bauhini*: its glands are, in general, more numerous towards the end than in any other part.

**ILIUM OS.** See **INNOMINATA OSSA**.

**ILLECEBRUM**, in botany, a genus of plants, whose flower is apetalous; the cup is pentaphyllous and quinqueangular, containing within it five capillary stamina. The fruit is an unilocular roundish capsule, acuminate on both sides, including a large single seed.

**IMAGE**, in a religious sense, is an artificial representation or similitude of some person or thing, used either by way of decoration and ornament, or as an object of religious worship and veneration; in which last sense, it is used indifferently with the word idol. See the article **IDOLATRY**.

**IMAGINATION**, a power or faculty of the mind, whereby it conceives and forms ideas of things communicated to it by the outward organs of sense.

**IMBECILITY**, a languid, infirm state of body; which, being greatly impaired, is not able to perform its usual exercises and functions.

**IMBIBING**, the action of a dry porous body, that absorbs or takes up a moist or fluid one: thus, sugar imbibes water; a sponge, the moisture of the air, &c. See the articles **MOISTURE**, **HYGROMETER**, &c.

**IMBRICATED**, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house.

The term imbricated is likewise applied to some of the heart shells, from their being ridged transversely in the same manner.

**IMITATION**, in literary matters, the act of doing or striving to copy after, or become like to another person or thing.

**IMITATION**, in music, a particular way of composition wherein each part is made to imitate the other, either throughout the whole piece, which is

one of the kinds of canon; or only during some measures, which is a simple imitation.

Sometimes the motion or figure of the notes is only imitated, and that often by a contrary motion, which makes what they call a retrograde imitation.

**IMMACULATE**, something without stain, chiefly applied to the conception of the holy virgin. See **CONCEPTION**.

**IMMANENT**, in logic. The schoolmen distinguish two kinds of actions, the one transient, which pass from the agent to the patient; the other immanent, which continue in the agent. See **ACT**.

**IMMATERIAL**, something devoid of matter, or that is pure spirit: thus God, angels, and the human soul, are immaterial beings. See the articles **GOD**, **ANGEL**, and **SOUL**.

**IMMEDIATE**, whatever is capable of producing an effect without the intervention of external means; thus we say, an immediate cause, in opposition to a mediate or remote one. See the article **CAUSE**.

**IMMEMORIAL**, in law, an epithet given to the time or duration of any thing, whose beginning we know nothing of.

**IMMENSITY**, an unlimited extension, or which no finite and determinate space, repeated ever so often, can equal. See **INFINITY**.

**IMMERSION**, that act by which any thing is plunged into water, or other fluid. See **FLUID**.

Immersion, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being, as it were, enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense emersion stands opposed to immersion, and signifies the moment wherein the moon begins to come out of the shadow of the earth, or the sun begins to shew the parts of his disk which were hid before. See the article **ECLIPSE**.

Immersion is frequently applied to the satellites of Jupiter, and especially to the first satellite; the observation whereof is of so much use for discovering the longitude. The immersion of that satellite is the moment in which it appears to enter within the disk of Jupiter, and its emersion the moment when it appears to come out.

The immersions are observed from the time of the conjunction of Jupiter with the sun, to the time of his opposition; and the emerions from the time of his opposition to his conjunction.

The peculiar advantage of these observations is, that

that during eleven months of the year, they may be made at least every other day. The perfection of this theory, and the praxis thereon, we owe to Mr. Cassini.

**IMMORTAL**, that which will last to all eternity; as having in it no principle of alteration or corruption: thus God and the human soul are immortal. See the articles **GOD** and **SOUL**.

**IMMUNITY**, a privilege or exemption from some office, duty, or imposition; as an exemption from tolls, &c.

**IMMUTABILITY**, one of the divine attributes, founded on the absolute perfection of the Deity. See **GOD**.

**IMPALED**, in heraldry; when the coat of a man and his wife who is not an heiress are borne in the same escutcheon, they must be marshalled in pale; the husband's on the right side, and the wife's on the left: and thus the heralds call baron and feme, two coats impaled.

If a man has had two wives, he may impale his coat in the middle between theirs; and if he has had more than two, they are to be marshalled on each side of his in their proper order.

**IMPALPABLE**, that whose parts are so extremely minute that they cannot be distinguished by the senses, particularly by that of feeling.

**IMPANELLING**, in law, signifies the writing down, or entering into a parchment, list, or schedule, the names of a jury summoned by the sheriff to appear for such public services as juries are employed in. See the article **PANNEL**.

**IMPARLANCE**, in law, a petition in court for a day to consider, or advise, what answer the defendant shall make to the plaintiff's action; and is the continuance of the cause till another day, or a longer time given by the court.

**IMPASSIBLE**, that which is exempt from suffering, or cannot undergo pain or alteration.

**IMPASTATION**, in masonry, a term used for a work made of stucco, or stone, beaten and wrought up in manner of a paste.

**IMPASTING**, or **EMPASTING**, in painting. See **EMPASTING**.

**IMPATIENS**, in botany. See the article **BAL-SAMINA**.

**IMPEACHMENT**, an accusation and prosecution for treason and other crimes and misdemeanors.

**IMPEACHMENT of Waste**, is a prohibition or restraint from committing of waste upon lands or tenements.

**IMPEDIMENTS**, in law, are such hindrances as put a stop, or stay, to a person's seeking for his right by due course of law.

**IMPENETRABILITY**, in philosophy, that property of body, whereby it cannot be pierced by another: thus, a body, which so fills a space as to

exclude all others, is said to be impenetrable. See the articles **BODY**, **EXTENSION**, &c.

**IMPERATIVE**, one of the moods of a verb, used when we would command, entreat, or advise: thus, *go, read, take pity, be advised*, are imperatives in our language; but in the learned languages, this mood has a peculiar termination to distinguish it from others, as *i, or ito, go; lege, or legito, read, &c.* and not only so, but the termination varies, according as you address one or more persons, as *audi* and *audite*; *anselo, anselon, anse-toray, &c.*

**IMPERATOR**, in Roman antiquity, a title of honour conferred on victorious generals by their armies, and afterwards confirmed by the senate.

**IMPERATORIA**, master-wort, in botany, a plant whose leaves arise immediately from the root; the footstalks are seven or eight inches long, dividing into three short ones at the top, each sustaining a tribbate leaf; the flower-stalks arise about two feet high, divided into two or three branches, which are terminated by umbels of white flowers whose petals are split. The fruit is naked, round, and compressed, divided in two parts, and containing two oval furrowed seeds.

The root of this plant is fleshy, aromatic, and has a strong acrid taste. It is reckoned cordial and sudorific, and is an ingredient in many compositions.

**IMPERFECT**, something that is defective, or that wants some of the properties found in other beings of the same kind: thus mosses are called imperfect plants, because almost all the parts of fructification are wanting in them; and for the like reason, is the appellation imperfect given to the fungi and submarine plants.

**IMPERFECT FLOWERS**, those otherwise called stameneous. See the article **STAMINEOUS**.

**IMPERFECT NUMBERS**, such whose aliquot parts taken together, do either exceed or fall short of that whole number of which they are parts: they are abundant or deficient. See the articles **ABUNDANT** and **DEFICIENT**.

**IMPERFECT TENSE**, in grammar, a tense that regards some preterite tense, or denotes the thing to be at that time present, and not quite finished; as *scribebam, I was writing*.

**IMPERIAL**, something belonging to an emperor or empire, as imperial crown, imperial chamber, imperial cities, imperial diet, &c.

**IMPERSONAL VERB**, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons, as *deceat, operet, &c.* The impersonal verbs of the active voice end in *t*, and those of the passive in *tur*; they are conjugated through the third person singular of almost all the tenses and moods: they want the imperative

perative, instead of which we use the present of the subjunctive; as *pœniteat, pugnetur*; nor, but a few excepted, are they to be met with in the supines, participles, or gerunds.

**IMPERVIOUS**, a thing not to be pervaded, nor passed through, either by reason of the closeness of its pores, or the particular consideration of its parts.

**IMPETIGO**, in medicine, a name by which the leprosy of the Greeks is sometimes called. See **LEPROSY**.

**IMPETIGO** is also a species of itch attended with dry scales or scurf, and an uneasy pruriginous itching. See **ITCH**.

**IMPETUS**, in mechanics, a force with which one body impels or strikes another. See **MOMENTUM**, **GUNNERY**, &c.

**IMPING**, in falconry, the inserting of a feather in the wing of an hawk, in the place of one that is broken.

**IMPLEAD** signifies to sue or prosecute by due course of law.

**IMPLEMENTS** is used for all things necessary for a trade, or the furniture of an household; in which sense it is frequently used in wills, conveyances of moveables, &c.

**IMPLICATION**, in law, is where something is implied that is not expressed by the parties themselves in their deeds, contracts or agreements.

**IMPORTATION**, in commerce, the bringing merchandize into a kingdom from foreign countries; in contradistinction to exportation. See the article **EXPORTATION**.

**IMPOSITION of Hands**, a religious ceremony, in which the bishop lays his hands upon the head of a person, in ordination, confirmation, or in uttering a blessing. This practice is generally observed by the dissenters at the ordination of their ministers, when all the ministers present place their hands upon the head of him whom they are ordaining, while one of the body prays for a blessing on him and his future labours.

**IMPOSSIBLE**, that which cannot be done or effected.

A proposition is said to be impossible, when it contains two ideas, which mutually destroy each other, and which can neither be conceived nor united together in the mind: thus, it is impossible that a circle should become a square, because we conceive clearly that squareness and roundness destroy each other by the contrariety of their figure.

**IMPOST**, in law, signifies in general a tribute or custom; but is more particularly applied to signify that tax which the crown receives for merchandizes imported into any port or haven. See **DUTY**.

Some notwithstanding, distinguish imposts from customs, which last are rather the profits arising to

the king from goods exported. See the article **CUSTOMS**.

**IMPOSTS**, in architecture, the capitals of pillars, or pilasters, which support arches.

An impost, sometimes called chaptrel, is a sort of plinth, or little cornice, which crowns a pier, and supports the first stone whence an arch or vault commences. The imposts are conformable to their proper orders. The Tuscan has only a plinth; the Doric has two faces crowned; the Ionic, a larmier, or crown over the two faces, and its moulding may be carved; the Corinthian and Composite have a larmier, freeze, and other mouldings.

The projectures of the imposts must not exceed the naked of the pilaster: sometimes the entablature of the order serves for the impost of the arch, and this has a very grand and stately appearance. The impost is a thing very essential to the composition of the ordonnances, insomuch that without it, in the place where the curve-line of the arch meets with the perpendicular line of the pillar, there always seems a kind of elbow.

**IMPOSTHUME**, in surgery, &c. the same with abscess.

**IMPOTENCE**, or **IMPOTENCY**, in general, denotes want of strength, power, or means to perform any thing.

**IMPRACTICABLE CASE**, in algebra, that otherwise called irreducible. See **IRREDUCIBLE**.

**IMPRECATION**, a curse, or wish that evil may befall any one. See **EXECRATION**.

**IMPRESSION** is applied to the species of objects, which are supposed to make some mark or impression on the senses, the mind, and the memory.

**IMPRESSION** also denotes the edition of a book, regarding the mechanical part only; whereas edition, besides this, takes in the care of the editor, who corrected or augmented the copy, adding notes, &c. to render the work more useful. See **EDITOR**.

**IMPRISONMENT**, the state of a person restrained of his liberty, and detained under the custody of another.

**IMPROPRIATION**, a parsonage or ecclesiastical living, the profits of which are in the hands of a layman; in which sense, it stands distinguished from appropriation, which is where the profits of a benefice are in the hands of a bishop, college, &c. though these terms are now often used promiscuously. See the article **APPROPRIATION**.

**IMPUTATION**, in general, the charging something to the account of one, which belonged to another: thus, the assertors of original sin maintain, that Adam's sin is imputed to all his posterity. See the article **ORIGINAL SIN**.

In the same sense, the righteousness and merits of Christ are imputed to true believers. See the article **JUSTIFICATION**.

**INACCESSIBLE**, something that cannot be come at, or approached, by reason of intervening obstacles, as a river, rock, &c. It is chiefly used in speaking of heights and distances. See **HEIGHT** and **DISTANCE**.

**INACTIVITY** of Matter. See **INERTIA**.

**INADEQUATE IDEA**. See **IDEA**.

**INALIENABLE**, that which cannot be legally alienated or made over to another: thus the dominions of the king, the revenues of the church, the estates of a minor, &c. are inalienable, otherwise than with a reserve of the right of redemption.

**INAMELLING**, or **ENAMELLING**. See the article **ENAMELLING**.

**INANIMATE**, a body that has either lost its soul, or that is not of a nature capable of having any.

**INANITION**, among physicians, denotes the state of the stomach when empty, in opposition to repletion.

**INARCHING**, in gardening, is a method of grafting, commonly called grafting by approach. See **GRAFTING by approach**.

**INAUGURATION**, the coronation of an emperor or king, or the consecration of a prelate: so called from the ceremonies used by the Romans, when they were received into the college of augurs. See **CORONATION**, **CONSECRATION**, &c.

**INCAMERATION**, a term used in the chancery of Rome, for the uniting of lands, revenues, or other rights, to the pope's domain.

**INCANTATION**, denotes certain ceremonies, accompanied with a formula of words, and supposed to be capable of raising devils, spirits, &c.

**INCAPACITY**, in the canon-law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimization in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

**INCARNATION**, in theology, the act whereby the second person of the Holy Trinity assumed the human nature, viz. a true body and reasonable soul, in order to accomplish the redemption of fallen mankind. See **TRINITY** and **REDEMPTION**.

**INCARNATIVES**, in surgery, medicines which assist nature in filling up wounds or ulcers with flesh; or rather remove the obstructions thereto. See the article **VULNERARY**.

Internal incarnatives are aliments which supply a balsamic chyle, and consequently generate flesh, and produce a full or plump habit.

**INCARTATION**, among chemists, the same with **depart**. See **DEPART**.

**INCENSE**, or **FRANK INCENSE**, in the materia medica. See the article **THUS**.

**INCEPTIVE**, a term used by Dr. Wallis to express such moments, or first principles, which, though of no magnitude themselves, are notwith-

standing capable of producing it. Thus, a point is inceptive of a line, and a line inceptive of surface, &c.

**INCEST**, the crime of venereal commerce between persons who are related in a degree wherein marriage is prohibited by the law of the country.

**INCEST SPIRITUAL**, a crime committed in like manner between persons who have a spiritual alliance by means of baptism or confirmation.

**INCH**, a well known measure of length; being the twelfth part of a foot, and equal to three barley corns in length. See **FOOT** and **MEASURE**.

**INCH of Candle**, or **fale by inch of candle**. See the article **CANDLE**.

**INCIDENCE**, in mechanics and optics, denotes the direction on which one body strikes on another. See **ANGLE**.

**INCIDENT**, in law, something that inseparably belongs to another: thus, a court baron is incident to a manor.

**INCIDENT**, in poetry, denotes much the same with **episode**. See **EPISODE**.

**INCISIVE**, an appellation given to whatever cuts or divides: thus, the fore-teeth are called *dentes incisivi*, or cutters; and medicines of an attenuating nature, incidents, or incisive medicines. See the articles **TEETH** and **ATTENUANTS**.

**INCLE**, a kind of tape made of linen-yarn.

**INCLINATION** is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning of two lines, or two planes, towards each other, so as to make an angle.

Inclination of a right-line to a plane, is the acute angle which that line makes with another right-line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic, or the angle contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arch of the circle of inclination, comprehended between the ecliptic and the plane of a planet in its orbit.

The greatest inclination of Saturn, according to Kepler, is  $2^{\circ} 32'$ ; of Jupiter,  $1^{\circ} 20'$ ; of Mars,  $1^{\circ} 50' 30''$ ; of Venus,  $3^{\circ} 22'$ ; of Mercury,  $6^{\circ} 54'$ . According to De la Hire, the greatest inclination of Saturn is  $2^{\circ} 33' 30''$ ; of Jupiter,  $1^{\circ} 19' 20''$ ; of Mars,  $1^{\circ} 51' 00''$ ; of Venus,  $3^{\circ} 25' 5''$ ; of Mercury,  $6^{\circ} 52' 00''$ .

**INCLINATION of a Plane**, in dialling, is the arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them.

**INCLINED PLANE**, in mechanics, that which makes an oblique angle with the horizon.

That an inclined plane is a mechanical power appears

Fig. 1.

Fig. 2. Inclind Plane.

Fig. 3. Turners Lathe and Wheel.

Fig. 4. Lathe.

Fig. 7. Lathe for turning Oval and Rose Work.

Fig. 5. Brasiers Lathe.

Fig. 6. An Iron Lathe for turning small Work in Metal.

pears sufficiently in its diminishing the weight of a body laid upon it, in regard to the power which holds it in æquilibrium. Let A (plate LXIV. fig. 1.) be a body sustained on the inclined plane BD; from the center C draw CF perpendicular to the horizon or base DC, and CE perpendicular to the plane; then CF will represent the whole weight or force of gravity of the body A, which is resolvable into the two forces CE and EF; but the force CE, being perpendicular to the plane, acts wholly upon it, and is equally re-acted on, or sustained by, the plane; the other force EF, being parallel to the plane, is that by which the body descends, or is kept from descending by an equal power acting in a contrary direction. Therefore the whole weight of the body is to the power which keeps it in æquilibrium on the plane, as CF to FE, or (because the triangles CFE and BDC are similar) as BD to BC, that is, as the length of the plane to its height.

If it should be required to lift up a very heavy body, as W or  $w$  (fig. 2.) the height CB, it would be impracticable to raise it up in the line CB without a power whose intensity is equal to that of the weight; and even in that case very inconvenient to do it, especially in building. But if an inclined plane AB be laid arising from the horizontal line AC, from whence the weight is to be raised, a less power than the weight will serve for that purpose, unless it pushes the body directly against the plane (as in the direction WT) or draws the body away from the plane (as from W towards  $e$ ,  $t$ , or L) or in any direction on that side of the line Ee.

The direction in which the body can most easily be drawn or pushed up the plane, is the line WwM, parallel to the plane, and passing through the center of the weight; for whether the power divides a plane  $kK$  (in a direction perpendicular to it) along the line WM, or the power P (by its descent to  $p$ ) draws it in the same line, the velocity of the power will be equal to the line Ww, the space described by the center of gravity of the weight, whilst the same weight rises only the perpendicular height ZB ( $=W$ ) or has the said line properly to express its velocity. If the body was a cylinder, as a rolling-stone, and the plane Tt were to pass through the gudgeons or axis of the said stone, it is evident that the case would be the same; and as the weight P has its rope running over the roller (or upper pulley) M, the line Pp will be the velocity of the power. Therefore, in this case, the weight (if kept in æquilibrium) will be to the power, as Ww ( $=TB$ ) to wY ( $=BZ$ ) or as the hypotenuse AB is to the perpendicular BC, which (by Eucl. 4, 6) are in the same proportion; and consequently, if the power be never so little increased, it will draw the weight up the plane.

That the power acts with the greatest advantage, whilst it draws in the line of direction Ww (parallel to the plane) is evident, because if one end of the

said plane of direction remaining fixed at W, the other should move towards B, or beyond it, then the body would be partly drawn against the plane, and therefore the power must be increased in proportion to the greatest difficulty of traction: and if the end  $w$  of the line above-mentioned should be carried to D, or beyond it, the power must be also increased, inasmuch as it endeavours to lift the body off from the plane.

If the power draws in a line of direction WB (fig. 2.) parallel to the base of the plane, then, in order to keep the weight W in æquilibrium by the power  $\Pi$ , the said power must be to the weight, as ZB to ZT, or as the perpendicular BC to the base AC of the triangle ACB. For if we suppose the pulley R at so great a distance from W, that the line of direction WR may not sensibly alter its horizontal position, whilst the body W rises the height BZ, in such manner that  $\Pi w$  ( $=WY$ , and not  $Ww$ ) will be the velocity of the power. So that the velocity of the power to that of the weight will not be as the hypotenuse to the perpendicular, as in the former case, but as the base to the perpendicular in the triangle ACB.

If the powers be increased just enough to overcome the friction of the plane and draw up the body W, let the pulley R be lifted up gradually to  $r$ , so as to keep the line WR parallel to itself till it comes to  $wr$ , and the power will be descended to  $\pi$ , when the weight is come to  $wB$ . But  $\Pi \pi$  together with the distance Rr, is equal to  $\Pi w$ , or WY, &c. And this traction, being constantly made in the angle WBT, is the case.

**INCLINERS, or INCLINING DIALS.** See the article DIALLING.

**INCLOSURE**, in husbandry, the fence or hedge made to inclose lands. See the articles FENCE and HEDGE.

A very good inclosure may be made of elder-sticks, or truncheons, cutten or twelve feet long, and stuck into the bank slopewise, so as to make a chequer-work. These make the speediest shelter of any; and when the trees are grown up, they are valuable for the turner's use. They succeed extremely well in watery places; and when planted on the banks of rivers, they prevent them from being undermined by the current.

The throwing down inclosures is an offence punishable by our ancient statutes; yet if the lord of a manor incloses part of the waste, and does not leave sufficient room for the commoners, they may break down such inclosures, or have a writ of assize.

**INCOGNITIO, or INCOG.** is applied to a person that is in any place where he would not be known: but it is more particularly applied to princes or great men, who enter towns or walk the streets without their ordinary train, or the usual marks of their distinction and quality.

**INCOMBUSTIBLE**, something that cannot be burnt or consumed by fire.

**INCOMMENSURABLE**, a term in geometry, used where two lines when compared to each other, have no common measure, how small soever, that will exactly measure them both. And, in general, two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal or side of a square; for though each of those lines have infinite aliquot parts, as the half, the third, &c. yet not any part of the one be it ever so little, can possibly measure the other, as is demonstrated in prop. 17, lib. x. of Euclid.

Rappus, lib. iv. prop. 17, speaks also of incommensurable angles. As to surfaces which cannot be measured by a common surface, they are said to be incommensurable in power.

**INCOMMENSURABLE NUMBERS** are such as have no common divisor that will divide them both equally.

**INCOMPATIBLE**, that which cannot subsist with another without destroying it: thus cold and heat are incompatible in the same subject, the strongest overcoming and expelling the weakest.

**INCORPOREAL**, a thing, or substance, which has no body; as God, angels, and the soul of man.

**INCRASSATING**, in pharmacy, &c. the rendering fluids thicker by the mixture of other substances less fluid, or by the evaporation of the thinner parts.

**INCREMENT**, and **DECREMENT**, the increase and decrease of a quantity. See the article **SERIES**.

**INCRUSTATION**, in surgery, the induction of a crust or eschar upon any part.

Among masons, incrustation signifies the lining or coating of a wall, either with glossy stones, rustics, marble, pottery, or stucco-work, and that either equably or in panels and compartments.

**INCRUSTED**, or **INCRUSTATED COLUMN**, is a column consisting of several pieces, or slips of some precious marble masticated or cemented round a mould of brick, or other matter.

**INCUBATION**, the action of a hen, or other fowl, brooding on her eggs.

**INCUBUS**, or **EPHIALTES**, in physic, commonly called the night-mare, a disorder under which the patient cannot stir himself, but with the utmost difficulty; is seized with a numbness and sense of weight, with a dread of suffocation, and an oppression, as from some body falling suddenly upon him.

The cure consists in evacuations by phlebotomy and cathartics. The patient must be kept to a thin diet, and avoid all flatulent food.

**INCUMBENT**, a clerk, or minister, who is resident on his benefice: he is called incumbent,

because he does, or at least ought to bend his whole study to discharge the cure of his church.

**INCURVATION** of the Rays of Light, their bending out of a rectilinear or straight course, occasioned by refraction. See **REFRACTION**.

**INCUS**, in anatomy, a bone of the internal ear. See the article **EAR**.

**INDEFEISIBLE**, or **INDEFEAZABLE**, a term in law, for what cannot be defeated or made void; as an indefeisible estate of inheritance, &c.

**INDEFINITE**, or **INDETERMINATE**, that which has no certain bounds, at least assignable by the human mind.

Descartes uses the word instead of infinite; in numbers and quantities, to signify a number so great, that an unit cannot be added to it; and a quantity so great, as not to be capable of any addition.

**INDEFINITE**, in the schools, also denotes a thing that has but one extreme; for instance, a line drawn from any point and extended infinitely; as also eternity *a parte ante*, or eternity *a parte post*.

**INDEFINITE Proposition**. See the article **PROPOSITION**.

**INDEFINITE**, in grammar, implies such nouns, pronouns, verbs, participles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, or other circumstance.

**INDELIBLE**, something that cannot be cancelled or effaced.

**INDEMNITY**, in law, the saving harmless; or a writing to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates, is called a warranty. See the article **WARRANTY**.

*Act of INDEMNITY*, the same with *act of grace*. See *Act of GRACE*.

**INDENTED**, in heraldry, is when the out-line of an ordinary is notched like the teeth of a saw.

**INDENTED Line**, in fortification, the same with what the French engineers call *redent*; being a trench and parapet running out and in, like the teeth of a saw; and is much used in irregular fortification. See **FORTIFICATION**.

**INDENTED Leaf**, among botanists, is one whose margin ends in horizontal points that are of the consistence of the leaf, and are separated by intermediate spaces.

**INDEPENDENTS**, a sect of protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to religious government within itself, and is no way subject or accountable to other churches or their deputies.

The present independents differ from the presbyterians only in their church government, in being generally more attached to the doctrines distinguished by the term orthodoxy, &c. and in administering

ministering the Lord's supper at the close of the afternoon's service. See the article PRESBYTERIANS.

The several sects of baptists are all independents with respect to church government.

**INDETERMINATE**, in general, an appellation given to whatever is not certain, fixed, and limited; in which sense, it is the same with indefinite.

**INDETERMINATE PROBLEM**, in algebra, one which is capable of an indefinite number of solutions.

**INDEX**, in anatomy, the same with the forefinger. See FINGER.

**INDEX**, in arithmetic and algebra, shews to what power any quantity is involved, and is otherwise called exponent. See EXPONENT.

**INDEX of a Logarithm**, that which shews of how many places the absolute number belonging to a logarithm doth consist; and of what nature it is, whether an integer or fraction. Thus, in this logarithm 2.523421, the number 2 standing on the left hand of the point is called the index, because it shews that the absolute number answering to the above logarithm, consists of three places: for the number is always one more than the index.

If the absolute number be a fraction, then the index of the logarithm hath a negative sign, marked thus 2.523421. See the article LOGARITHM.

**INDEX of a Globe**, the little style or gnomon, which being fixed on the pole of the globe, and turning round with it, points out the hours upon the hour circle. See the article GLOBE.

**Expurgatory INDEX**, a catalogue of prohibited books in the church of Rome.

**INDIAN-SHOT**, in botany. See the article CANNA.

**INDICATION**, in physic, whatever serves to direct the physician how to act.

**INDICATIVE**, in grammar, the first mood, or manner, of conjugating a verb, by which we simply affirm, deny, or ask something; as *amant*, they love; *non amant*, they do not love; *amas tu*, dost thou love?

**INDICATIVE Column**. See COLUMN.

**INDICTION**, in chronology, a cycle of fifteen years. See CYCLE.

**INDICTMENT**, in law, is a bill or declaration of complaint, at the suit of the king, drawn up in form of law, and exhibited against a person, and afterwards preferred to the grand jury or inquest, who are to find whether the complaint be true or not. An indictment differs from an accusation only in this, that the preferrer of the bill is not tied to the proof thereof, under any penalty, except there appear to be a conspiracy.

**INDIGESTION**, *Indigestio*, a want of due coction, either in the food, the humours of the body, or excrements.

**INDIGNATORIUS MUSCULUS**, a muscle of the eye, otherwise called abducens, and rectus exterior: it has this appellation from its drawing the eye outwards, thereby occasioning the appearance of scorn. See the article EYE.

**INDIGO**, in commerce, a preparation of the juice of a plant, whose leaves are small, fleshy, and soft, of a greenish brown colour on the upper side, pale, and as it were silver-coloured underneath. This plant, by some called anil, or nil, has several slender knotty stalks, which spread into small branches, clothed each with from four to ten pair of these leaves, and an odd one at the end: it rises to the height of about two feet, and produces reddish flowers, in shape resembling those of broom, but smaller, followed by oblong pods, containing the seeds.

Labat has given a particular account of the culture of the plant, and the preparation of the indigo. The ground being thoroughly cleared from weeds, one of the principal points in the culture, a number of slaves, ranged in a line, march across, making little trenches of the width of their hoes, and two or three inches deep, about a foot distance from each other every way: then returning, they drop some seeds in each trench, and afterwards cover them with the earth taken out. In moist weather, the plant comes up in three or four days; and in about two months after, it is fit for cutting: if suffered to stand till it runs into flower, the leaves become too dry and hard, and the indigo obtained from them proves less in quantity, and less beautiful: the due point in maturity is known, by the leaves beginning to grow less supple, or more brittle. In rainy seasons the cutting may be repeated every six weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford fresh crops for two years.

A large quantity of the herb is put into a vat or cistern of strong mason work, with so much water as is sufficient to cover it, and some wood laid above to prevent its rising up. The matter begins to ferment, sooner or later, according to the warmth of the weather, and the maturity of the plant, sometimes in six or eight hours, and sometimes in not less than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour inclining to violet. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpose, so as to be commanded by the first.

In the second vat the liquor is strongly and incessantly beat and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requisite in hitting this point: if the beating is ceased too soon, a part of the tinging matter remains dissolved in the liquor; if continued a little too long, a part of that which

had

had separated is dissolved afresh. The exact time for discontinuing the process is determined, by taking up some of the liquor occasionally in a little cup, and observing whether the blue fecula is disposed to separate and subside.

The whole being now suffered to rest till the blue matter has settled, the clear water is let off by cocks in the sides at different heights; and the blue part discharged by a cock in the bottom, into another vat: here it is suffered to settle for some time longer; then further drained in cloth bags, and exposed in shallow wooden boxes to the air, till thoroughly dry.

The author abovementioned, from whom the whole of the foregoing account is extracted, observes further, that the goodness of the indigo depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is less, but the colour proportionably more beautiful; that probably the secret of those, whose indigo has been most esteemed, is no other than cutting the herb at the time when it yields the finest colour; that the superiority of some of the indigos of the East-Indies to those of America, is perhaps owing to the former being prepared more curiously from only the leaves of the plant; and that by beating the herb in the steeping vat, which has been practised by some with a view to increase the quantity, great part of the substance of the leaves and bark is blended with the water along with the colouring matter, and the indigo extremely debased.

It is said that lime or lime-water is sometimes employed in the beating vat, to promote the separation of the tinging particles from the water; and that the hardness or flintiness of some sorts of indigo is owing to an over-proportion of this addition.

Indigo is commonly divided, from the colour which it exhibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is said that the dyers use chiefly the first; and the callico-printers, for this drug gives a durable stain to linen as well as woollen, the last. On what particular circumstances these different appearances depend, we know not; nor is it certainly known, whether the real quality of the indigo has any connexion with them. The deepest and liveliest indigo, rubbed with the nail, looks like polished copper; and solutions of all the sorts, made in alkaline lixivia, assume alike a copper-coloured skin upon the surface.

Good indigo is moderately light, breaks of a shining surface, and burns almost wholly away upon a red-hot iron. It is quickly penetrated by water, and reduced into a kind of paste: a considerable part is at the same time diffused through the liquor, and very slowly subsides. This is probably what Labat and Hellot mean by its dissolving in water; for no part of the indigo really dissolves; it cannot indeed be expected that it should from the process by which it is obtained.

**INDIVIDUAL**, *Individuum*, in logic, a particular being of any species, or that which cannot be divided into two or more beings equal or alike.

**INDIVISIBLE**, among metaphysicians. A thing is said to be indivisibly absolute, absolutely indivisible, that is a simple being, and consists of no parts into which it may be divided. Thus God is indivisible in all respects, as is also the human mind, not having extension or other properties of body.

**INDIVISIBLE** *Secundum quid est*, indivisible with respect to what is now is, a substance which, though it consists of parts into which it may be divided, yet never can be so divided as to remain the same: thus a measure or number is said to be indivisible, for if from a foot-line, for example, any thing is deducted, it is no more a foot-line; and if from the number three any thing is subtracted, it is no longer the same number. See the next article.

**INDIVISIBLES**, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; whence we may see that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but decreasing in arithmetical proportion, and so are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or surface of an isosceles cone. See the article **INFINITESIMALS**.

**INDORSEMENT**, in law, any thing written on the back of a deed, as a receipt for money received. See the article **BILL**.

**INDUCEMENT**, in law, signifies what may be alledged as a motive; and, in our law, it is used specially in several cases; as, there is an inducement to actions, to a traverse in pleading, and to an offence committed, &c.

**INDUCTION**, in law, is putting a clerk or clergyman in possession of a benefice or living to which he is collated or presented. See the article **PRESENTATION**.

**INDULGENCES**, in the Romish church, are a remission of the punishment due to sins, granted by the church, and supposed to save the sinner from purgatory. Clement VI. in his decretal, which is generally received by the church of Rome, declares, that our saviour has left an infinite treasure of merits, arising from his own sufferings, besides those of the blessed virgin and the saints; and that the pastors and guides of the church, and more especially the popes, who are the sovereign disposers of this treasure

sure, have authority to apply it to the living, by virtue of the keys, and to the dead, by way of suffrage, to discharge them from their respective proportions of punishment, by taking just so much merit out of this general treasure, as they conceive the debt requires, and offering it to God.

It was the great abuse of indulgences that contributed not a little to the first reformation of religion in Germany, where Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves: for since that time the popes have been more sparing in the exercise of this power; however, they still carry on a great trade with them in the Indies, where they are purchased at two reals a piece, and sometimes more.

**INDULT**, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope.

**INDULTO**, a duty, tax, or custom, paid to the king of Spain, for all such commodities as are imported from the West-Indies in the galleons. See the article **GALLEONS**.

**INERTIA of Matter**, in philosophy, is defined by Sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. It is also defined by the same author to be a power implanted in all matter whereby it resists any change endeavoured to be made in its state.

This power then coincides with the *vis resistendi*, or power of resisting, whereby every body endeavours, as much as it can, to persevere in its own state, whether of rest or uniform rectilinear motion; which power is still proportionable to the quantity of matter in any body: for since natural bodies consist of a mass of matter, that, of itself, is not able to induce any change in its state, if bodies were once at rest, it is necessary that they should always remain in that state of rest, unless there is applied a new force to produce motion in them: but if they were in motion, the same energy or force would always preserve the motion; and therefore bodies would always retain their motion, and would always proceed forward in the same right-line with the same tenor, since they cannot of themselves acquire either rest or a retardation, or a change of their direction to turn on one side or the other.

Since, according to this law, a body once in motion always continues in that motion, the philosophers ask, Why all projectiles lose by degrees their motion? Why do they not proceed in infinitum? If motion did not of its own nature decay, a stone thrown at the beginning of the world, would by this time gone through an immense and almost infinite space. And so indeed it would, if its motion had been in vacuo, or in free spaces, and without

any gravity. But since all projectiles are carried either through the air, or on the rough surfaces of other bodies, they must be necessarily retarded: for since all bodies in motion must drive and thrust out of its place the resisting air, or overcome the roughness of the superficies upon which they are moved, they will lose all that force and motion that is constantly employed in overcoming these obstacles, and consequently the motion of projectiles will be continually diminished: but if there was no resistance in the medium, no roughness in the superficies on which they were moved, no gravity that continually forces the bodies toward the earth, motion would always continue the same, without any retardation at all. So in the heavens, where the medium is exceedingly rare, the planets do continue their motions for a very long time; and upon ice, or any other very smooth surface without any roughness, heavy bodies in motion are not soon brought to rest.

**INFALLIBLE**, what cannot deceive, nor be deceived.

The word is Latin, and formed of *in*, taken privately, and *fallo*, to deceive.

**INFAMOUS**, in general, denotes something notoriously contrary to virtue or honour.

The word is derived from the Latin *in*, and *fama*, report.

**INFAMOUS**, in law, denotes a person of no repute in the world. There are two kinds of infamy; some persons being infamous *de jure*, or stigmatized by public judgments; others are infamous *de facto*, as being of a scandalous profession, as a catchpole, hangman, informer, &c.

**INFANT**, *Infans*, in medicine, denotes a young child. See the articles **CHILD** and **DELIVERY**.

**INFANT**, in law, signifies a person under the age of one and twenty.

**INFANTE** and **INFANTA**, all the sons and daughters of the kings of Spain and Portugal, except the eldest; the princes being called *infantes*, and the princesses *infantas*.

**INFANTRY**, in military affairs, denotes the whole body of foot-soldiers. See the articles **FOOT** and **SOLDIERS**.

**INFECTION**, among physicians, the same with contagion. See **CONTAGION**.

**INFERNAL-STONE**, *Lapis infernalis*. See the article **LAPIS**.

**INFINITE**, that which has neither beginning nor end: in which sense God alone is infinite. See the article **GOD**.

Infinite is also used to signify that which has had a beginning, but will have no end, as angels and human souls. This makes what the schoolmen call *infinitum a parte post*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end but had no beginning.

**INFINITE**, in mathematics, are such quantities

as are either greater or smaller than any assignable one, being the same with indefinite or indeterminate, to which no certain limits are prescribed.

The doctrine of infinites has given occasion for many disputes; but the true state of the case is this: So long as we reason upon wrong suppositions, we must never expect to arrive at truth; but the nearer our suppositions are to truth, the nearer will be the conclusion; and if these suppositions be infinitely near the truth, the errors in the conclusion will be infinitely small, which being at last thrown out of the account, the conclusion will be the same as if we had proceeded upon principles accurately true. This is the true rise of infinitely small quantities in all mathematical computations, and the true reason for rejecting them, when the operation is over. But it may be reasonably demanded, How do we know that these infinitely small errors in the conclusion arise from similar errors in the premises? And the answer is, because these two sorts of errors have so mutual a dependence one upon another, that one cannot be made to vanish, but the other will necessarily vanish with it. If it be further demanded, What the wrong suppositions are from which these infinitely small errors spring? We answer, in the first place, the supposing magnitudes to have quantity, which in reality have none at all, but have entirely lost it, either by running into infinity on the one hand, or into nothing on the other. Thus, if we suppose the point D to actually coincide with the angular point C (pl. LXIV. fig. 3.) the line DC will not only comparatively, but absolutely be equal to nothing; that is, it will be no line at all, nor can any use be made of it; but by allowing the said line to have some quantity, though extremely small, or less than any that can be assigned, we tacitly suppose the point D not to be actually in the angular point C, but infinitely near it.

A quantity, after it is reduced to nothing, ceases to be a quantity; and if 0 have no quantity, neither can its reciprocal  $\frac{1}{0}$ , or any magnitude expressed by it, be said to have any: but the reciprocal of nothing signifies a magnitude infinitely great in the strictest sense of the word, and can no more be said to have quantity than absolute nothing can; and to compare such magnitudes in respect of their quantity, which actually have none, is contrary to the definition both of ratios, and the object of proportion: nay, we know not whether the greatest part, if not all, the difficulties that are said to attend the idea of infinity, and our inability to comprehend it ought not rather to be charged upon the absurdity of comparing things together which in their own natures are incapable of all comparison. It is said indeed that infinite parallelopipeds, standing perpendicular upon finite bases, and upon the same plane, are in proportion as their bases; which is true; but this is not comparing magnitudes in respect of the quantity they have not, but in respect of the quan-

tity they have; one of these parallelopipeds may be said to be broader or thicker than another, though not higher. Thus, if  $r$  be any quantity whereof the multiples  $2r$  and  $3r$  are taken,  $2r$  may be said to be to  $3r$  as 2 to 3, whether  $r$  be finite or infinitely great or small; nay, though  $r$  should signify an impossible quantity; as  $\sqrt{-1}$ ,  $\sqrt{-2}$ , &c. but then the quantity of this proportion does not depend upon the quantity  $r$ , but upon the coefficients 2 and 3: but we must here take notice however, that if  $r$  be actually infinite, we mean in the strictest sense of the word, by  $2r$  and  $3r$  must then be meant, not quantities twice or thrice as big as  $r$ , in the same respect wherein it is infinite, but  $r$  twice or thrice taken, which is no way absurd; for if it be possible for any one infinite quantity to exist, that is not every way infinite, it will be as possible for others to exist of the same kind, independently of the former: a parallelopiped, that is infinitely extended only as to its length, and that both forwards and backwards, may however receive any addition, or be increased or diminished in any proportion in respect of its finite dimensions, but not in respect to its infinite dimensions; and this is all the proportion we can conceive infinite quantities capable of. See *Philosophical Transactions*, N°. 195.

That lines or quantities may continually decrease, and yet never become nothing, may be easily shewn in the following manner.—Let MCLK (fig. 4.) be an indefinite right line, P a given point out of that line; from P draw PCB perpendicular to MCLK, and of any length at pleasure; from P draw PE, PF, PI, &c. observing always to make the segments DE, TF, LI, &c. of these lines constantly equal to CB: from the points E, F, I, &c. let fall upon MCK the perpendiculars EG, FH, IK, &c. It is very evident that each following perpendicular is shorter than any of the preceding ones; and it is as evident, that were the number of them ever so great, the last perpendicular would be of a finite length, because its corresponding hypothenuse does, by the hypothesis, form a finite angle with the indefinite line MCLK, and does also constantly rise above it.

Mathematicians, and more especially those who understand this subject, are, generally speaking, reserved enough upon it, and chuse rather to be deficient than redundant in their expressions upon these occasions; not from any diffidence in their own principles, but knowing very well how liable matters of this nature are to be drawn into disputes by such as lie upon the catch, and make it their chief business to oppose the truths which they themselves could never have discovered, nor perhaps will ever be able to understand.

INFINITE Series. See SERIES.

INFIRMARY, a kind of hospital, where the weak and sickly are properly taken care of. See the article HOSPITAL.

# I N F

**INFLAMMABILITY**, that property of bodies, which disposes them to kindle, or catch fire. See the articles **FIRE**, **FLAME**, **HEAT**, &c.

**INFLAMMATION**, in surgery and medicine, is defined to be a pressure and attrition of the red arterial blood, stagnating in the smallest canals, produced by the motion of the rest of the blood, thrown into a violent and forcible commotion, by means of a fever.

This definition of an inflammation is taken from its causes. Others define it from its symptoms to be a species of a tumour attended with a burning heat, pain, redness, resistance, and a continual pulsation and pricking. See **TUMOUR**.

Inflammations are either external, being such as fall properly under the business of surgery, and are cured by manual operations and topical remedies; or internal, being such whose cure is to be expected chiefly from the use of internal remedies. See the article **FEVER**.

*General Crises and Cure of INFLAMMATIONS.* Inflammations terminate variously, according to their different degrees of violence, the causes from whence they arise, the parts which they effect, and the particular constitution of the patient, with several other circumstances which also preface to us what shall be the end of the inflammation. But the several ways wherein an inflammation terminates are chiefly four. It is either 1. so dispersed and resolved as to vanish without leaving any considerable injury in the part affected, and which afterwards recovers its former vigour, and is of all others, the best course it can take; or else, 2. the inflammation suppurates, and degenerates into an abscess, so as to leave ever after some damage in the organ; or else, 3. the inflammation degenerates into a gangrene, or sphacelus; or, lastly, into a hard tumour, commonly called a scirrhus, which grows more compact in the part affected, as the inflammation remits or goes off.

As to the resolution and dispersion of an inflammation, that is usually practicable, where it is only of a milder kind, in a sound habit of body, when the blood is not yet too viscid nor vehement in its motion. See the article **DISPERSION**.

But suppuration follows, when the inflammation is more violent, the circulation more rapid, but yet the mass of blood somewhat temperate, and without much acrimony: the treatment of an inflammation that terminates in a suppuration, the reader will find delivered under the articles **SUPPURATION**, **ABSCESS**, &c.

When the forementioned symptoms are much more violent, and when the blood is at the same time more acrimonious and rapid than it ought to be, the inflammation generally terminates in a gangrene. See the article **GANGRENE**.

But if the inflamed part be full of glands, and the blood very thick, glutinous, and inspissated, the

# I N F

small blood vessels are then so strongly stuffed up with glutinous blood, that they are compacted together, the parts lose their sensation, and are converted into an hard tumour, which is thence called a scirrhus. See the article **SCIRRHUS**.

*INFLAMMATION in the Breasts*, a disorder most incident to child bearing women, and almost constantly happens a few days after their delivery.

If the milk should be propelled too plentifully and forcibly into the breast, which at such times frequently happens; and if the mother should then be seized with cold, fear, anger, or a sudden perturbation of mind, the sanguiferous and lactiferous vessels being thence obstructed, the breasts must then become inevitably tumified, which will be attended with great heat, redness, resistance, and violent pain. The same accident often happens to women that give suck even a long time after their lying-in, and is sometimes the case of those who have no milk, all proceeding from the causes already mentioned; and Heister gives us an instance of a man's breast being inflamed by means of a great fright. These inflammations do not, according to that author, always happen to be equally intense and violent; for sometimes it seizes the whole breast; sometimes only one side; and at other times occupies only a small part of the breast: sometimes the inflammation lies very near the skin; at other times very deep; and at one time it has urgent symptoms, and at another, it sits easy on the part.

This disorder may be speedily removed in women of condition, and such as do not suckle their children, if some of the plaster of *sperma ceti* spread on linen be applied warm all round the breast soon after parturition; being perforated in the middle, to transmit the papilla or nipple; the accession of the milk being also repelled by a very strait bandage. Among the internal remedies, the most proper are such as bring down the lochia puerperarum, when they do not flow in sufficient plenty of themselves; the principle remedies for this purpose are the essence of myrrh, amber, the essence of saffron, elixir proprietatis, &c. Lastly, with respect to the proper drink, it must be carefully observed to diminish the quantity of milk by the smallness and poverty of the meat and drink, upon which account the patient should be recommended to drink small broth, tea, or the like watery liquors: and if the mother be desirous of suckling the infant, there can be no better preservative against the inflammations of the breasts. But when the inflammation is fixed, the cure must be attempted either by dispersion or suppuration, for the method of which see **DISPERSION** and **SUPPURATION**.

But it often happens that the tumour will neither yield to dispersion nor suppuration, and is in danger of turning to a scirrhus, or cancer, the patient must be kept in good spirits, and the plaster of *sperma*

*sperma ceti* be constantly retained on the tumour, by which means it will probably either grow less, or else vanish.

**INFLAMMATION of the Bladder**, that attended with an acute, burning, pressing pain, in the region of the pubes, a fever, and a continual tenesmus, or desire of going to stool, and a perpetual striving to make water.

Other symptoms of this disease are a rumbling of the bowels, griping pains, great anxiety of the præcordia, difficult breathing, want of appetite, and vomiting, coldness of the extreme parts, a hard, quick, unequal, contracted pulse, inquietude, and sometimes convulsions. There is another kind which is more superficial, and is either rheumatic or erysipelatous, in which the fever is more easily and speedily cured, by promoting a diaphoresis; and persons in years, who are affected with the scurvy, gout, rheumatism, or violent head-achs, are most subject to it, especially if they catch cold from a north wind. The former arises commonly from the stoppage of the menses, bleeding piles, or other usual sanguinary evacuations, and not seldom from a virulent gonorrhœa, unskilfully suppressed by astringents; or when treated by medicines of too sharp and hot a nature.

This disease is mortal, if it terminates in an ulcer, or mortification: the latter is immediate death.

The cure must be attempted, says Hoffman, with bleeding in the foot, if a suppression of the menses or hæmorrhoidal flux be the cause. If it proceeds from the scurvy, &c. recourse must be had to gentle diaphoretics, diluents, and remedies which obtund the acrimony of the humours, such as decoctions of the root of scorzonera, china, skirrets, and fennel. Also infusions in the manner of tea of the tops of yarrow, flower of mallows, winter cherries, and seed of daucus, made with milk, and sweetened with syrup of marsh-mallows. To these may be added emulsions of the four cold seeds. If the patient is costive, manna will be proper with antimonial nitre, to which rhubarb may be joined, as occasion requires. If the disease is violent, diaphoretic powders with nitre, in a larger proportion than ordinary, as also five grains of saffron, and two of camphire, with the emulsions aforesaid. External antispasmodics, and gentle discutients will be proper; for which purpose it was Hoffman's method to apply bladders, filled with a decoction of emollient flowers. If the tenesmus and difficulty of urine arise from spasms, there is nothing better than the vapours of a decoction in milk of the flowers of melilot, elder, chamomile, and mallows, and the tops of yarrow. This decoction may be put into a close-stool, and the patient sit over it.

**INFLAMMATION of the Brain**. See PHRENSY.

**INFLAMMATION of the Diaphragm**. See the article PARAPHRENITIS.

**INFLAMMATION of the Eyes**. See the article OPHTHALMIA.

**INFLAMMATION of the Fauces**. See the article QUINSEY.

**INFLAMMATION of the Intestines**, according to Boerhaave, is an inflammation contracting the intestines, and stopping up the passage through them; attended with a vehement, fixed, burning pain, which is irritated by things taken inwardly.

When the inflammation is in the upper part of the intestines, the stomach will be greatly distended with wind. When the pain is exasperated, it produces convulsions of the diaphragm and abdominal muscles, vomiting, and painful inflations, with rumblings and sharp griping pains, which may bring on the iliac passion, or twisting of the guts. Hoffman says, that when there is a burning pain in the abdomen, with a preternatural heat of the whole body, as also a quick pulse, loss of strength, anxiety and inquietude, the seat of the disease may justly be suspected to be in the intestines. If the pain is above the navel, and below the stomach, attended with a fever, nausea, and reaching, it is a sign that that part of the colon is affected which lies beneath the stomach, and is extended from the right to the left side. If the pain lies in the right hypochondrium, under the spurious ribs, it shews that part of the colon to be inflamed where it joins with the ilium. When the complaint is on the left side, under the loins, where the psoas muscle is placed, it is a sign that the colon, and that part of the mesentery joined thereto, is the seat of the disease, especially when it adheres to the peritonæum: but when the pain is in the middle of the abdomen about the navel, it shews the small guts are certainly affected; in all which cases, the pain is supposed to be attended with a fever.

Arbuthnot advises, that this disease be carefully distinguished from a colic, proceeding from a cold cause; because what is good for the latter is poison in the former. It must have a speedy remedy, or it will soon, according to that writer, end in the iliac passion, or a mortification. Besides copious bleeding, he thinks there is scarcely any other method of cure, than fomenting and relaxing the bowels with emollient liquids taken warm, both by the mouth and in clysters, and this every hour: warm fomentations, or young, vigorous, and sound animals applied to the body are extremely beneficial.

Boerhaave directs, that the patient should only be nourished with broth, in which gentle detergent roots have been boiled.

After bleeding and clysters, if the pain continues violent, Hoffman is of opinion, that there will be no manner of danger in giving opiates, by which means the excruciating pain will be alleviated, and the spasms appeased, and a breathing sweat will follow. When this is done, and the fever abated, there will be no occasion to continue the dilating,

relaxing, and moistening medicines, but rather the nervous and corroborating; such as the preparations of amber, especially the salt and tincture; the former of which may be given in a bolus from six to sixteen grains, and the latter from twenty to eighty drops, in any convenient vehicle.

If the patient survives three days, and the acuteness of the pain abates with a chilliness and shivering throughout the whole body, it is a sign of a suppuration; and within fourteen days the imposthume will break, and if it falls into the cavity of the abdomen, it will corrupt the whole mass of fluids, putrify the viscera, and turn to an ascites; whence the patient will die of a consumption. In this case, Boerhaave and Arbuthnot recommend whey and chalybeate waters, as likely to prove most beneficial. The imposthume may turn either to a gangrene or scirrhus, both which are mortal.

*INFLAMMATION of the Kidneys.* See the article NEPHRITIS.

*INFLAMMATION of the Liver.* When the liver is inflamed, it compresses the stomach, diaphragm, and the neighbouring viscera of the abdomen; it stops the circulation of the fluids, hinders the generation and excretion of the gall, and all digestion; it produces a great many bad symptoms, as the jaundice, with all the diseases depending thereon. See HEPATASIS.

A fever, an inflammation, and pungent pain on the region of the liver, and diaphragm, a tension of the hypochondria, yellowness of the skin and eyes, and a saffron-coloured urine, are signs of an inflammatory disposition of the liver. See JAUNDICE.

This disease terminates as other inflammations; being cured by resolution, concoction, and excretion, of the morbid matter; or it terminates in an abscess, scirrhus, or gangrene. See ABSCESS, &c.

During the first state, Arbuthnot tells us, that a warm regimen and saffron, which some reckon a specific, are improper. On the other hand, that cooling resolving liquors, taken inwardly, as whey with sorrel boiled in it, outward fomentations, and frequent injections of clysters, bathing and frictions, relax and render the matter fluid. Honey, with a little rhenish wine and vinegar, the juices and jellies of some ripe garden fruits, and those of some lactescent plants, as endive, dandelion, and lettuce, are resolvent. Violent purging hurts; gently relaxing the belly relieves, diluents with nitrous salts are beneficial, or tamarinds boiled in warm water, or whey. The feverish matter is often carried off by urine, and therefore diuretics, not highly stimulating, are proper.

If the inflammation be recent, extremely violent, and without any signs or hopes of resolution, concoction, and excretion, Boerhaave advises, that the case be treated with the same cautions and remedies as are directed in pleurisy, and other similar inflammatory disorders; such remedies only excepted,

as the situation of the part affected cannot admit of, except only, that all antiphlogistic fluids, either drank or injected by clysters, are particularly serviceable in the case before us.

*INFLAMMATION of the Lungs.* See the article PERIPNEUMONY.

*INFLAMMATION of the Pleura.* See the article PLEURISY.

*INFLAMMATION of the Stomach* is known by a burning, fixed, and pungent pain in the stomach, which is exasperated at the instant any thing is taken into it, and is succeeded by a most painful vomiting and hiccough. There is, besides, an inward heat, anxiety, and a tenfive pain about the præcordia, an acute continual fever, great thirst, difficult breathing, inquietude, tossing of the body, coldness of the extreme parts, a hard, contracted, quick, and sometimes unequal, pulse. In the medical essays, we have an instance in this disease being attended with a hydrophobia. See the article HYDROPHOBIA.

Boerhaave says, that this disease, if not suddenly cured, is generally mortal: therefore, that as soon as it is discovered, plentiful bleeding is necessary; that the patient's drink should be very soft, antiphlogistic, and emollient; and also that clysters of the same kind should be administered.

Arbuthnot advises, that the patient should totally abstain from every thing that has acrimony in it; even the cooling nitrous salts, which are beneficial in other inflammations, irritate too much. Vomits, cordials, and spirituous liquors, are little better than poison: milk generally curdles. Aliments must be given frequently, and by a spoonful at a time, for any distention increases the inflammation. A thin gruel of barley, oatmeal, whey, with a very little sugar or honey, or chicken broths, are proper aliments: whey emulsions, barley-water, and emollient decoctions are proper drinks. If poisons of the caustic kind, or metallic medicines ill prepared, cause the inflammation, oily fat things are proper, as new milk, cream, oil of sweet almonds, or oil of olives taken often and plentifully, according to Hoffman. If in the cholera morbus an inflammation is apprehended, he advises absorbents and burnt hart's horn, with gelatinous decoctions of calves and neats feet, or hartshorn-jellies, and water-gruel. Outwardly he recommends the following liniment as useful in all cases; take oil of sweet-almonds, two ounces; camphire, one dram; make a liniment, with which anoint frequently the præcordia, applying a hot linen cloth over it. The following epithem he recommends as an excellent discutient and sudorific. Take of the vinegar of roses, two ounces; spirit of wine camphorated, two drams; tincture of saffron, and tincture of castor, of each one dram; nitre, half a dram: let this epithem be applied warm to the region of the stomach.

If there happens an imposthume, honey, and even

honey of roses, taken inwardly, is, according to Arbuthnot, a good cleanser; and decoctions of comfrey-roots, healing.

*INFLAMMATION of the Womb or Uterus*, appears from extraordinary heat and a fixed pain in the groin; with an acute fever, a pain in the loins and belly, an inflation of the abdomen, a stimulus to make water and to go to stool, heat, and a difficulty of urine.

Other symptoms, according to Astruc, are a tumor, pain, heat, tension of the hypogastric region, redness of the os uteri, and great heat of the vagina. If the fore part of the uterus is affected, there is a dysury; if the back part, a tenesmus; frequent faintings and cardialgia, a burning fever; or, if the inflammation is violent, a lipyria, in which the external parts or extremities are cold, and the internal burn, and the pulse is imperceptible; a delirium and phrensy; the breasts swell, in proportion as the inflamed uterus.

Hoffman distinguishes this disease into the superficial and more profound. He says, that it is easily formed in child-bed women, and frequently accompanies the milk-fever, and may be cured in a few days if rightly managed. But that when it is more intense, and attended with grievous symptoms without remission, it kills on the seventh, ninth, or eleventh day; a white miliary fever generally supervenes, which is the worst omen, as it shews a mortification of the uterus. See the article MILIARY FEVER.

**INFLAMMATORY DISEASES.** To these may be referred the several diseases mentioned in the preceding article, either attended with a fever, or lesser inflammation without a fever; besides all chronic disorders arising from inflammations, the chief of which are old coughs, consumptions, and the rheumatism, without a fever. See COUGH.

**INFLAMMATORY FEVERS** are distinguished into two stages; the first, whilst the pulse continues hard, in which it is proper to bleed; the second, when the inflammatory symptoms still remaining, the pulse is too low for that evacuation; in this state blisters are the chief remedy, and which, except in a few singular cases, are not to be used sooner. If the blisters are large, it is better to apply them gradually, than many at a time. See FEVER and INFLAMMATION.

*Point of INFLECTION.* When a curve AFK (plate LXIV. fig. 5.) is partly convex, and partly concave, to a right line AB or point B; the point F dividing the convex from the concave part, or the end of the one, and the beginning of the other, is called the point of inflection, when the curve being come to F, continues its course towards the same parts; and the point of retrogression, when the curve returns back again towards the place of its beginning.

Let us suppose the curve AFK to have the right line AB as a diameter, and the ordinates PM, EF, &c. parallel to each other. Now if you draw the ordinate FE from the point F, and the tangent FL; also another ordinate MP from the point M in the concave part AF of the curve, likewise a tangent MT; then it is evident that, in curves having a point of inflection, while the absciss AP constantly increases, the part AT of the diameter, intercepted between the vertex of the diameter A and the point T, where the tangent meets the diameter, does likewise increase until the point P falls in E, after which it continually decreases; therefore AT must become a maximum AL, when the point P falls in E, the point sought.

In those curves that have a point of retrogression, the part AT continually increases, and the absciss AP till the point T coincides with L, and afterwards it continually decreases; whence AE must be a maximum, when the point T coincides with L.

Now call AE,  $x$ ; EF,  $y$ ; then will  $AL = \frac{yx}{y} = x$ , and the fluxion of this will be  $\frac{yyx - yxx}{yy} = \frac{y}{y}$ , supposing  $x$  invariable; which (being divided by  $x$  the fluxion of AE) must be equal to nothing, or infiniteness: whence  $\frac{y}{y} = 0$ , or infinity; and so multiplying by  $yy$ , and dividing by  $-y$ , there comes out  $y = 0$ , or infinite.

Now, with this last expression, and the general equation of a curve, the point of inflection or retrogression F may be found: for the nature of the curve AFK being given, we shall have a value of  $y$  in  $x$ , and putting that value into fluxions with  $x$  constant, we shall obtain a value of  $y$  in terms of  $xx$ ; which being made equal to 0, and afterwards to infinity, by means thereof, in either of these suppositions, we may find AE so expressed, that its correspondent ordinate EF shall intersect the curve in the point of inflection or retrogression F.

Let the ordinates BM, BF, BM, of the curve AFK, all meet in the same point B: if any ordinate BM (fig. 6.) be drawn, and the tangent MT meeting BT (fig. 7.) perpendicular to BM in the point T; and if  $m$  (fig. 8.) be taken infinitely near M, and the ordinate Bm, tangent  $mt$ , the perpendicular Bt to Bm meeting MT in O, be all drawn: then supposing the ordinate BM, becoming Bm to increase, it is plain, in the concave part of the curve, that Bt is greater than BO; and in the convex part the same is less. So that under the point of inflection or retrogression F, Ot must change from negative to positive.

This being premised, about the center B describe the small arches MR, TH, and there will be formed the similar triangles mRM, MBT, THO, and the little similar sectors BMR, BTH. Now put

put  $BM = y$ ,  $MR = \dot{x}$ , then  $mR(\dot{y}) : RM(\dot{x}) :: BM(y) : BT = \frac{y\ddot{x}}{\dot{y}} : MR(\dot{x}) : TH = \left(\frac{\dot{x}\ddot{x}}{\dot{y}}\right) : TH$   
 $\left(\frac{\dot{x}\ddot{x}}{\dot{y}}\right) : HO = \frac{\dot{x}\ddot{x}\dot{y}}{\dot{y}\dot{y}}$ . Now take the fluxion of  $BT$   
 $\left(\frac{y\ddot{x}}{\dot{y}}\right)$  with  $\dot{x}$  invariable, and there will arise  $Bt -$   
 $BT$  or  $Ht = \frac{\dot{x}\dot{y}\ddot{y} - y\ddot{x}\dot{y}}{\dot{y}\dot{y}}$ ; and therefore  $OH + Ht$   
or  $Ot = \frac{\dot{x}^3 + x\dot{y}^2 - y\dot{x}\ddot{y}}{\dot{y}^2}$ . Whence multiplying by

$\dot{y}^2$ , and dividing by  $\dot{x}$ , the expression  $\dot{x}^2 + y^2 - y\dot{y}$  must be nothing or infinite in the point of inflection or retrogression F. Now, by the nature of the curve given, we shall have values of  $\dot{y}$  in  $\dot{x}$ , and of  $\dot{y}$  in  $\dot{x}^2$ , which being substituted in  $\dot{x}^2 + y^2 - y\dot{y}$ , there will be produced a quantity, which being made equal first to nothing, and afterwards to infinity; by means thereof we may get such a value of BF, that if a circle may be described from B, with the same as a radius, it shall cut the curve AFK (fig. 5.) in the point of inflection or retrogression F.

Example 1. Let AFK (fig. 9) be a curve, the right-line AB being a diameter of it, and let the relation of any absciss AE ( $x$ ) to its corresponding ordinate EF ( $y$ ) be expressed by this equation,  $ax^2 = yx^2 + a^2y$ . It is required to find such an expression for AE, that the ordinate EF shall intersect the curve AFK in the point of inflection F.

The equation of the curve gives  $y = \frac{ax^2}{x^2 + a^2}$ , and therefore  $\dot{y} = \frac{2ax\dot{x}}{x^2 + a^2}$ , and by taking the fluxion of this quantity with  $\dot{x}$  constant, there will arise  $\frac{2a^3x^2 \times x^2 + a^2 - 8ax^2x^2 \times x^2 + a^2}{x^2 + a^2}$ , which being made

equal to nothing, and divided by  $2a^3x^2 \times x^2 + a^2$ , will produce  $x^2 + a^2 - 4x^2 = 0$ . Whence AE ( $x$ )  
 $= \frac{a}{\sqrt{3}}$ .

If  $\frac{1}{3}aa$  be put for its equal  $xx$  in the equation of the curve  $y = \frac{ax^2}{x^2 + a^2}$ , we shall have  $y = \frac{a}{4}$ ; so that the point of inflection F may be determined without supposing the curve AFK to be described.

If AC be drawn parallel to the ordinates EF, and made equal to the given right-line  $a$ , and CG be drawn parallel to AB, the same will be an asymptote to the curve AFK. For if  $x$  be made infinite, we may take  $xx$  for  $xx + aa$ , and therefore the value of  $y$  will then become equal to  $a$ .

Example 2. Let AFK (fig. 10.) be the conchoid of Nicomedes, and the point P the pole, the right-line BC the asymptote. It is required to find the point of inflection F; the nature of the curve being such, that a right-line PF, drawn from any point F in it to the pole P, meeting the asymptote

BC in D, the part DF thereof is always equal to a given and constant quantity  $a$ .

Draw PA perpendicular, and EF parallel to BC, also DL parallel to BA. Put  $BE = x$ ,  $EF = y$ , then by the similar triangles DLF, PEF,  $DL(x) : LF$   
 $(\sqrt{a^2 - x^2}) : PE(b + x) : EF(y) = \frac{b + x \times \sqrt{a^2 - x^2}}{x}$

The fluxion of this will be  $\dot{y} = \frac{x^3\dot{x} + a^2b\dot{x}}{x^2\sqrt{a^2 - x^2}}$ . Now

if you take the fluxion of it again, and make the same equal to nothing, there will arise

$\frac{2a^4b - a^2x^3 - 3a^2bx^2 \times \dot{x}^2}{a^2x^3 - x^5 \times \sqrt{a^2 - x^2}} = 0$ , which may be reduced to  $x^3 + 3bx^2 - 2a^2b = 0$ ; and one of the roots thereof will be the quantity of BE sought.

If  $a = b$ , the equation foregoing will become  $x^3 + 3ax^2 - 2a^3 = 0$ , which divided by  $x + a$ , gives  $xx + 2ax - 2aa = 0$ ; and thence  $x$  or BE equal to  $\sqrt{3a^2} - a$ .

INFLECTION, in grammar, the variation of nouns and verbs, by declension and conjugation. See DECLENSION and CONJUGATION.

INFLEX LEAF, among botanists, one whose point bends inward, towards the stem of the plant. See the article LEAF.

INFLUENCE, a quality supposed to flow from the heavenly bodies, either with their light or heat; to which astrologers idly ascribe all sublunary events.

IN FORMA PAUPERIS, in law. See the article FORMA.

INFORMATION, in law, is nearly the same in the crown-office, as what in our other courts is called a declaration.

INFORMER, a person that informs against or prosecutes another, upon any penal statute.

INFORMIS, something irregular in its form, or figure. See the articles FIGURE and FORM.

Hence, *stellæ informis*, in astronomy, are such of the fixed stars as are not reduced into any constellation. See the articles CONSTELLATION and STAR.

INFRA LAPSARIANS, in church-history, an appellation given to such predestinarians, as think the decrees of God, in regard to the salvation and damnation of mankind, were formed in consequence of Adam's fall. See PREDESTINATION.

INFRA SCAPULARIS, in anatomy, one of the depressor-muscles of the arm, which has its origin from the whole internal surface of the scapula, and its termination in the interior part of the humerus. See the article DEPRESSOR.

INFRA SPINATUS, in anatomy, one of the abductor-muscles of the arm, which has its origin in the cavity below the spine of the scapula. See the article ABDUCTOR.

INFUNDIBILIFORM, an appellation given by

by botanists to those flowers whose corollæ are monopetalous and funnel-shaped, having a narrow tube at one end, and gradually widening towards the limb or mouth. There are two kinds of these flowers, one the figure of a cone, and the other plain or flat, somewhat like a saucer, and thence called hypocrateriform; of the first kind is bugloss, and of the last form is turnsole, with many other genera.

**INFUSION**, in pharmacy, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

**INGANNO**, in music, is when having done every thing proper for ending a cadence, a mark of silence is placed instead of the final, which the ear naturally expects, and is deceived. See **CADENCE**.

**INGOT**, a mass of gold or silver, melted down and cast in a mould, but not coined or wrought. See **GOLD** and **SILVER**.

**INGREDIENTS**, in pharmacy, whatever simple medicine enter the composition of a compound one.

**INGRESS**, in astronomy, signifies the sun's entering the first scruple of one of the four cardinal signs; especially Aries.

**INGRESS**, **EGRESS**, and **REGRESS**, in law, words frequently used in leases of lands, which signify a free entry into, a going out of, and returning from some part of the premises leased to another.

**INGROSSER**, one who buys up great quantities of any commodity, before it comes to market, in order to raise the price.

**INGROSSER** also signifies a clerk or person who copies records, deeds, or other instruments of law, on skins of parchment.

**INGUEN**, in anatomy, the same with what is otherwise called groin, or bubes. See **PUBES**.

**INGUINAL**, in anatomy, &c. any thing belonging to the groin. Hence,

**INGUINAL HERNIA** is a hernia in that part, called by surgeons bubonocèle. See **BUBONOCELE**.

**INHARMONICAL RELATION**, in music, is much the same with discord.

**INHERITANCE**, a perpetual right or interest in lands, invested in a person and his heirs.

**INHIBITION**, a writ to forbid a judge's proceeding in a cause that lies before him.

**INHUMATION**, in chemistry, a method of digesting substances, by burying the vessel in which they are contained in horse-dung or earth. See the article **DIGESTION**.

**INJECTION**, in surgery, the forcibly throwing certain liquid medicines into the body by means of a syringe, tube, clyster-pipe, or the like.

*Anatomical INJECTION*, the filling the vessels with some coloured substance, in order to make their figures and ramifications visible.

**INITIATED**, in antiquity, a term chiefly used in speaking of persons who were admitted to a participation of the sacred mysteries among the heathens. See the article **MYSTERY**.

**INJUNCTION**, in law, is a writ or kind of prohibition granted in several cases; and for the most part grounded on an interlocutory order or decree, made in the court of chancery or exchequer for staying proceedings either in courts of law, or ecclesiastical courts.

**INJURY**, any wrong done to a man's person, reputation, or goods. See the articles **ASSAULT**, **TRESPASS**, &c.

**INK**, *Atramentum*, a black liquor generally made of an infusion of galls, copperas, and a little gum-arabic.

*Composition of common Black INK.* — "Take one gallon of soft water, and pour it boiling hot on one pound of powdered galls, put into a proper vessel; stop the mouth of the vessel; and set it in the sun in summer, or in winter where it may be warmed by any fire; and let it stand two or three days. Add then half a pound of green vitriol powdered; and having stirred the mixture well together with a wooden spatula, let it stand again for two or three days, repeating the stirring; when add further to it five ounces of gum-arabic dissolved in a quart of boiling water; and, lastly, two ounces of alum; after which the ink should be strained through a coarse linen cloth for use."

The galls should be good, or the ink will fail; as it very frequently does from an error in this point. The marks of their goodness is, the appearing of a bluish colour, and feeling heavy. Where they are light in weight, and of a whitish brown colour, without any blue, they should be rejected; or a greater proportion should be used.

In most of the recipes for the making of ink, gum-arabic is ordered to be put undissolved into the mixture of water, galls, and vitriol; but, however common, it is certainly a very injudicious practice; for as the gum-arabic is with some difficulty dissolved in simple water, and much more so in such as is acidulated by salts like the vitriol, and clogged likewise with the solid part of the galls, it is certainly much better to make a solution of it in part of the water of which the ink is to be formed, previously to its being commixed with the other ingredients; which would otherwise, in spite of the most frequent stirrings, keep it at the bottom of the vessel, and prevent its being ever wholly freed from them, and dissolved.

Boiling either the infusion of the galls, or the mixture after the addition of the vitriol, has likewise been frequently ordered, and practised: but it is not only needless, but injurious to the preparation of the ink; as it can have no effect on the vitriol, besides conducing to the solution of it, which is easily effected, in the proportion of water proper

per to be used, without any heat; and with respect to the galls, their tinging power residing in an essential oil that is volatile, and will rise with less heat than that of boiling water, it is necessarily lessened by the evaporation; and consequently, though more of it may be extracted from the galls, yet less will be retained in the fluid, than if infusion with a gentle heat be used, instead of decoction.

*Preparation of Red-writing INK.*—"Take of the raspings of Brazil-wood a quarter of a pound, and infuse them two or three days in vinegar, which should be colourless, where it can be so procured. Boil the infusion then an hour over a gentle fire; and afterwards filter it, while hot, through paper, laid in an earthen cullender. Put it again over the fire, and dissolve in it, first half an ounce of gum-arabic, and afterwards of alum and white-sugar, each half an ounce."

Care should be taken that the Brazil-wood be not adulterated with the Braziletto or Campeachy, commonly called peachy-wood, which is mostly the case when it is ground; and though a very detrimental fraud, in all instances of the application of Brazil-wood to the forming bright red colours, cannot yet be perceived after the mixture of the raspings, but by trial in using them; it is therefore much the best way, when it is wanted for purposes like this, to procure the true Brazil-wood in pieces, and to scrape it with a knife, or rasp it with a very bright file; but all rust of iron must be carefully avoided, by which means all possibility of sophistication is of course prevented.

Red-ink may likewise be prepared by the above process, of white-wine instead of vinegar; but it should be four, or be disposed to be so; otherwise, a third or fourth of vinegar should be added, in order to its taking the stronger tincture from the wood. Small-beer has been sometimes used for the same purpose, but the ink will not be so bright; and when it is used, vinegar should be added, and the quantity of gum-arabic diminished, and the sugar wholly omitted.

*Preparation of Red-INK from Vermilion.*—"Take the glair of four eggs, a tea-spoonful of white-sugar or sugar-candy beaten to powder, and as much spirit of wine; and beat them together till they be of the consistence of oil: then add such a proportion of vermilion as will produce a red colour, sufficiently strong; and keep the mixture in a small phial, or well stopped ink-bottle for use. The composition should be well shaken together before it be used."

Instead of the glair of eggs, gum-water is frequently used: but thin size made of isinglass with a little honey, is much better for the purpose.

*Indian-INK*, is a black pigment brought hither from China, which on being rubbed with water, dissolves, and forms a substance resembling ink, but of a consistence extremely well adapted to the working with a pencil; on which account, it is not only

much used as a black colour in miniature painting, but is the black generally made use of for all smaller drawings in *chiaro obscuro*, or where the effect is to be produced from light and shade only.

The preparation of Indian-ink, as well as of the other compositions used by the Chinese as paints, is not hitherto revealed on any good authority; but it appears clearly from experiments, to be the coal of fish-bones, or some other vegetable substance, mixed with isinglass-size, or other size; and most probably, honey, or sugar-candy, to prevent its cracking. A substance, therefore, much of the same nature, and applicable to the same purposes, may be formed in the following manner:

"Take of isinglass six ounces, reduce it to a size, by dissolving it over the fire in double its weight of water; take then of Spanish-liquorice one ounce, and dissolve it also in double its weight of water, and grind up with it an ounce of ivory-black: add this mixture to the size while hot; and stir the whole together till all the ingredients be thoroughly incorporated: then evaporate away the water in *balneo marie*, and cast the remaining composition into leaden moulds greased, or make it up in any other mould."

The colour of this composition will be equally good with that of the Indian-ink: the isinglass size, mixed with the colours, works with the pencil equally well with the Indian-ink: and the Spanish-liquorice will both render it easily dissolvable on the rubbing with water (to which the isinglass alone is somewhat reluctant) and also prevent its cracking and peeling off from the ground on which it is laid.

**INLAYING**, the art of marquetry. See **MARQUETRY**.

**INNATE IDEAS**, those supposed to be stamped on the mind, from the first moment of its existence, and which it constantly brings into the world with it: a doctrine which Mr. Locke has abundantly refuted. See the article **IDEA**.

**INNOCENTS DAY**, a festival of the Christian church, observed on December 28, in memory of the massacre of the innocent children by the command of Herod, king of Judea; who, being alarmed at hearing that an infant was born king of the Jews, and imagining that his own kingdom was in danger, sent orders to have all the children slain that were in Bethlehem, and the adjacent country.

The Greek church in their calendar, and the Abyssinians of Ethiopia in their offices, commemorate fourteen thousand infants on this occasion.

**INNOMINATA OSSA**, in anatomy, three bones, which compose the extreme part of the trunk of a human body. These, though single in adults, are in infants three perfectly distinct bones, each of which has its peculiar name; the upper one is called the ileum; the anterior one, the os pubis, or os

pectinis;

pectinis; and the posterior one, the os pubis, or os ischium. These are joined by the intervention of a cartilage, as it were, in the middle of that singular cavity called the acetabulum, and continue visibly distinct to the age of puberty; after which they coalesce, and form one entire bone so perfectly, that there is not the least vestige remaining that they ever were separate.

INNUENDO, a word that was frequently used in declarations of slander, and law pleadings, when these were in Latin, in order to ascertain a person or thing before-mentioned; but now, instead of the word innuendo, we say, meaning so and so.

INOCULATION, in medicine, the art of transplanting a distemper from one subject to another, by incision, particularly used for engrafting the small-pox. See the article Pox.

The design of this operation is to communicate by art a milder species of the small-pox to the infant or adult patient, than that received by the natural infection; and this by engrafting some of the variolous matter, in order to which a small incision is to be first made with a scalpel or lancet, through the skin of the arm; and having inserted a small particle of the purulent matter, taken from a mild kind of the pock, the little wound is then to be dressed with some dry lint, and covered with a plaster. After the operation, the patient must constantly keep his chamber, the air of which should be moderately warm, and his diet regulated by some prudent physician, by which means this disorder will shew itself in seven or eight days, without any malignant symptoms; and if assisted by a proper regimen, and a moderate warmth, it usually runs through its several stages. When the patient has once had the disorder this way, though ever so mild, it is certain, from experience, that they never have it again; and therefore the opinion of those seems to be well grounded, who think that the propagation of the small-pox by inoculation might be of general use and benefit to mankind in preserving the lives of some, and the most important members of others, as the face, eyes, hearing, viscera, &c.

History informs us, that the disorder was this way propagated many hundred years ago, among the Greeks, Turks, and Chinese; whereas it is but of late years that the European nations have come into it, among which the English seem to have approved and followed it most. The experiment succeeded so well in the hands of the British physicians, that king George I. countenanced the same in all his dominions, and from thence the practice prevailed with success in Germany, particularly in the dominions of Hanover.

INOCULATION, or budding, in gardening, a kind of grafting practised in the summer months on several kinds of stone fruits, as peaches, nectarines, cherries, plumbs, apricots, &c. also upon oranges, jasmynes, and various other sorts of plants,

which succeed better by this practice than the common methods of grafting. In order to perform which, being provided with a sharp knife having a flat haft made for the purpose, as also with the cuttings of the tree intended to be propagated, proceed to make choice of a smooth part of the stock intended to be inoculated; if designed to be dwarf, five or six inches from the ground, but if a standard, it should be budded at the height of five and a half or six feet; then with your knife make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards about two inches in length, being careful not to cut deeper than the thickness of the bark, lest the stock is wounded; then having the cutting ready, cut off the leaf from the bud, leaving the footstalk remaining; cut the bud off lengthways, somewhat longer than the slit in the stock, with part of the wood to it; this done, with your knife slip the wood from the bark with a sudden jerk, and observe whether the eye of the bud is left or not, for those buds which lose their eyes in stripping are useless; then with the handle of the knife gently raise the bark on each side of the slit in the stock, and insert the bud therein, observing to place it smooth between the rind and wood of the stock, cutting off that part of the rind of the bud which may happen to be too long for the slit made in the stock; so having exactly fitted the bud to the stock, tie them closely round with wetted strong bafs, taking care not to bind round the eye of the bud, which should be left open. In about three weeks or a month the buds will require to be loosened of the bandage, which if not done in time will be very injurious to them, but not to be intirely divested of the binding, as it is not amiss to slightly tie them again, which will prevent the bark of the stock from flying open, as sometimes happens, whereby the bud is much injured, if not entirely destroyed.

The March following, the stock should be cut off about three inches above the place of inoculation, sloping it the contrary way to the bud; this length is of use to fasten the shoot which proceeds from the bud, which otherwise might be blown out by strong winds; but the autumn following, it should be cut close just above the bud, that the place of amputation may the more readily be barked over.

The time for inoculation is from the middle of June to the latter end of August, according to the season and the forwardness of the different sorts of trees intended to be budded, which must be known by trying if the buds will separate from the wood easily. The first sort of fruit commonly inoculated is the apricot, and the last the orange; although the orange is commonly budded in August, it is very proper to try the operation in July, which I have done with success; and those stocks which miscarry may be budded the succeeding month, or even

even in September ; but let it be done when it will, it is proper to put them in a gentle heat, giving plenty of water, by which means their success will be but little dubious.

In doing this work it will be necessary to take the opportunity of cloudy moist weather, as the bud and stock will more readily unite, being more replete with juices than in hot dry weather, when the stock will perspire so fast as to leave the buds destitute of moisture.

**INORDINATE PROPORTION** is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus, suppose the numbers in one rank to be 2, 3, 9 ; and those of the other rank 8, 24, 36 ; which are compared in a different order, viz.  $2:3::24:36$  ; and  $3:9::8:24$ . Then rejecting the mean terms of each rank, you conclude  $2:9::8:36$ .

**INOSCULATION**, in anatomy, the same with anastomasis. See **ANASTOMASIS**.

**INQUEST**, in law, signifies an enquiry made by a jury, in a civil or criminal cause, by examining witnesses. See the article **JURY**.

**INQUIRENDO**, in law, an authority given to one or more persons, to enquire into something for the advantage of the king.

**INQUISITION**, in law, a manner of proceeding by way of search or examination used on the king's behalf, in cases of out-lawry, treason, felony, self-murder, &c. to discover lands, goods, and the like, forfeited to the crown.

**INQUISITION**, in the church of Rome, a tribunal in several Roman-catholic countries, erected by the popes for the examination and punishment of heretics.

**INQUISITORS**, in law, persons who have power by their office to make inquiry into certain cases ; as sheriffs, and coroners on view of the body.

**INROLLMENT**, in law, is registering any lawful act, as a statute or recognizance acknowledged, a deed of bargain and sale, &c. in the rolls of chancery, king's bench, common pleas, or exchequer, at the hustings of Guildhall, London, or at the quarter-sessions.

**INCONSED**, in the military art, part of an army that have fortified themselves with a sence or small fort, in order to defend some pass, &c.

**INSCRIBED**, in geometry. A figure is said to be inscribed in another, when all its angles touch the sides or planes of the other figure. See **HEXAGON**, **PENTAGON**, &c.

**INSCRIPTION**, a title or writing carved, engraved, or affixed to any thing, to give a more distinct knowledge of it, or to transmit some important truth to posterity.

**INSECTS**, *Insecta*, in natural history, a smaller

kind of animals, that commonly are exsanguinous.

The word is Latin, and derived from *in*, and *seco*, to cut, because in some insects, as ants, the body seems divided into two ; or because the bodies of several of them, as worms, &c. consist of divers rings, which are a sort of incisure.

As to the generation of insects, the world is now generally convinced that they are not bred of corruption, but *ex ovo*, though the contrary was believed by the ancients.

Malpighi, Swammerdam, and Redi, have abundantly confuted the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly ; and have shewn, that all the members of the butterfly were inclosed under the nympha or skin of the caterpillar, as the parts of a plant are in the seed.

Insects take particular care to deposit their eggs or semen in such places where they may have a sufficient incubation, and where the young, when hatched, may have proper food till they can shift for themselves. Those whose food is in the water, lay their eggs there : those to whom flesh is a proper food, in flesh ; and those to whom the fruits or leaves of vegetables are food, are accordingly deposited there, but constantly the same kind in the same tree. As for others that require a greater degree of warmth, they are provided by the parent with some place in or about the body of other animals, as the feathers of birds, hair of beasts, scales of fish, in the nose ; in the flesh, nay some in the bowels of man, and other creatures. And as for others, they make them nests, by digging into the earth, wood, &c. carrying in and sealing up provisions that serve for the production of their young, and for their food when produced.

There is observed in flies, butterflies, &c. a kind of glue, by which the female fastens her eggs to the bearing buds of trees, &c. so as not to be hurt by rain or frost.

Mr. Andry, in his *Treatise de la generation des vers dans le corps de l'homme*, takes notice, that the ancients were mistaken in denying that insects breathed, on account of their wanting lungs ; for modern observations convince us, that insects have a greater number of lungs than any other animals ; they also thought that they had no blood, as many of them had no red liquor like ours ; but it is not the colour, but the use of the liquor, that is to be regarded. They also believed that they had no hearts ; whereas our microscopes now discover that, when insects have several lungs, they have also several hearts ; and this in particular is observable in silk-worms, who have a continued chain of hearts from the head almost to the extremity of the tail ; and, as is apparent from several insects, who give signs of life, long after they are divided into several parts.

# I N S

Insects want no parts that are either necessary or convenient for their use, or to render them complete in their kind. Some affirm that earth worms, and those round-tailed worms, which are found in the intestines of men, horses, &c. as also snails and horse-leeches, are hermaphrodites; but that such worms as become flies, and that silk-worms, are not so, being of no sex, but nests full of real animals, which in time come out with wings.

**INSIDIANT DISEASES**, those which shew no symptom, but lie concealed in the body, ready to break forth on the least provocation, as it were by surprize.

**INSITION**, in gardening, the same with grafting. See **GRAFTING**.

**INSOLATION**, in chemistry, the suffering matters to stand and digest in the heat of the sun, instead of that of a furnace. See the articles **FIRE** and **HEAT**.

**INSOLVENT**, a term applied to persons unable to pay their debts. See the articles **DEBT** and **DEBTOR**.

**INSPIRATION**, *Inspiratio*, the conveying certain supernatural notices to the soul. This is such an overpowering impression made of any proposition upon the mind by God himself, as gives an indubitable evidence of the truth and divinity of it.

**INSPIRATION**, in phycic, that part of respiration whereby the air is drawn into the lungs, and stands contradicting distinguished from expiration.

This admission of the air depends immediately on its elasticity, when the cavity of the breast is enlarged by the elevation of the thorax and abdomen, and particularly by the motion of the diaphragm downwards. This dilatation of the breast does not draw in the air, though it be a condition absolutely necessary to inspiration, but it is an actual intrusion of the air into the lungs.

**INSPISSATING**, **INSPISSATION**, or **CONDENSATION**, in pharmacy, the reducing a liquor to a thicker consistence by evaporating the thinner parts. See **INCRASSATING**.

**INSTALLMENT**, the inflating a person in any dignity.

The word is derived from the Latin *installo*, which is compounded of *in*, and *stallum*, a seat in a church, bench in a court of justice, &c.

It chiefly denotes the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his proper seat in a cathedral church. This is sometimes called installation.

**INSTALLMENT** likewise denotes the ceremony, whereby the knights of the garter are placed in their rank in the chapel of St. George at Windsor.

**INSTANT**, such a part of duration wherein we perceive no succession, or it is that which takes up the time of an idea in our minds.

The schoolmen distinguish three kinds of in-

# I N F

stants; a temporary, a natural, and a rational instant.

**Temporary instant** is a part of time immediately preceding another: thus the last instant of a day precedes, immediately and really, the first instant of the following day.

**Natural instant** is what we otherwise call a priority of nature, which obtains in things that are subordinated in acting, as first and second causes, or causes and their effects: for the nature of things requires, that if there be a second cause there must be a first; and that there must be a cause, if there be an effect. See **CAUSE**.

**Rational instant** is not any real instant, but a point which the understanding conceives to have been before some other instant, founded on the nature of the thing which occasioned it to be conceived: for instance, if God made several things voluntarily, which he could otherwise have let alone, there is a reasonable foundation to conceive God such as he is in himself, before he had made any of these voluntary determinations: but as there was no real instant when God had not formed any determination, this instant is called a rational instant, by way of opposition to an instant of time.

**INSTAURATION**, the re-establishment or re-stitution of a religion, a church, or the like, to its former state.

**INSTEP**, in the manege, is that part of a horse's hind leg which reaches from the ham to the pastern joint; and which, when the horse is in his natural posture of standing, should be large, flat, and in a perpendicular line with the ground: for when the insteps do not stand perpendicularly, it is a certain sign of weakness either in the reins or hinder quarters.

**INSTINCT**, an appellation given to the sagacity and natural inclinations of brutes, which supplies the place of reason in mankind. See the articles **REASON** and **BRUTE**.

**INSTITUTES**, in literary history, a book containing the elements of the Roman law, and constitutes the last part of the civil law. See the article **CIVIL LAW**.

**INSTITUTION**, in general, signifies the establishing or founding something.

**INSTRUMENT**, in general, whatever is subservient to a cause in producing any effect.

A common case of mathematical instruments contains several compasses, a sector, scale, drawing-pen, and protractor. See the articles **COMPASSES**, **SECTOR**, **SCALE**, &c.

**INSTRUMENT**, in law, some public act, or authentic deed, by which any truth is made apparent, or any right or title established in a court of justice. See the article **DEED**.

**INSULATED**, *Insulatus*, in architecture, an appellation given to such columns as stand alone, or free

free from any contiguous wall, &c. like an island in the sea, whence its name.

**INSULT**, *insultus*, in medicine, signifies the access of the paroxysm of intermitting diseases.

**INSULT**, in the art of war, the same with assault. See **ASSAULT**.

**INSURANCE**, or **ASSURANCE**, a contract or security, which is commonly called policy, given by one or more persons, whereby they oblige themselves, in consideration of a sum of money paid down, to make good ships, merchandizes, houses, &c. to the value of that for which the premium is received, in case of loss by storm, pirates, fire, &c.

We have in London several offices of insurance from fire, which are erected into corporations, as the Royal Exchange assurance, the Sun-fire-office, the Hand-in-Hand fire-office, the London-assurance, the Phoenix-office, &c. some for houses, others for goods, and some for both.

There are also offices wherein private merchants grant insurances for ships, and these are called insurance brokers.

We have also assurances for life, by virtue of which, when the person assured dies, a sum of money, according as he insured, becomes payable to the person in favour of whom the policy of assurance was granted. See the article **POLICY of Assurance**.

**INTACTÆ**, in conics, an appellation sometimes given to the asymptotes. See the article **ASYMPTOTES**.

**INTAGLIOS**, precious stones on which are engraved the heads of great men, inscriptions, and the like, such as we frequently see set in rings, seals, &c.

**INTEGER**, in arithmetic, a whole number, in contradistinction to a fraction. See **NUMBER** and **FRACTION**.

**INTEGRAL**, or **INTEGRANT**, in the schools, denotes those parts which are necessary to the integrity of any whole, and so stand contradistinguished from essential parts. The arms, &c. are integral parts of a man; body and soul are essential parts.

**INTEGRAL Calculus**, in the new analysis, is the counter part to the differential calculus. The latter hath been fully explained by M. l'Hospital; but the former hath been but little cultivated.

The integral calculus of Leibnitz and others answers to the inverse method of fluxions among the English.

**INTENDMENT**, in law, is the intention, design, or true meaning of a person or thing, which frequently supplies what is not fully expressed: but though the intent of parties in deeds and contracts is much regarded by the law, yet it cannot take place against the rules of law.

**INTENDMENT of Crimes**; this in case of treason, where the intention is proved by circumstances,

is punishable in the same manner as if it was put in execution.

**INTERCALARY DAY**, in chronology, the odd day inserted in a leap-year. See the article **BISSEXTILE**.

The word is Latin, *intercalaris*, and derived from *inter*, and *calo*, which anciently signified to call with a loud voice: an intercalary day among the Romans, signifying a day inserted between two other days, which for that reason was proclaimed by the priests with a loud voice.

**INTERCEPTED AXIS**, in conic sections, the same with absciss. See **ABSCISS**.

**INTERCOLUMNIATION**, in architecture, implies the space between two columns, which is always to be proportioned to the height and bulk of the columns.

**INTERCOMMONING**, in law, is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously on them.

**INTERCOSTAL**, in anatomy, an appellation given to such muscles, nerves, arteries, and veins, as lie between the ribs. See **RIB**.

**INTERDICT**, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c.

**INTEREST**, a sum of money which is reckoned for the loan and forbearance of some other sum lent for, or due at, a certain time, according to a certain rate in the hundred pounds. The sum lent or forborn is called the principal, because it produces the interest, or from which the interest is reckoned. Interest is either simple or compound.

*Simple* **INTEREST** is that which is paid for the loan of any principal or sum of money lent out for some time at any rate, per cent. agreed on between the borrower and the lender; which, according to the laws of England, ought to be but 5% for the use of 100*l.* for one year, and 10*l.* for the use of 100*l.* for two years; and so on for a greater or less sum, proportionable to the time proposed.

There are several ways of computing or answering questions about simple interest; as by the single and double rule of three; others make use of tables composed of several rates per cent.

But we shall shew, that all computations relating to simple interest, are grounded upon arithmetical progression; and from thence raise such general theorems as will suit with all cases. In order to that,

Let  $P$  = any principal or sum put to interest.

$R$  = the ratio of the rate per cent. per annum.

$t$  = the time of the principal's continuing at interest.

$A$  = the amount of the principal and its interest.

Note. The ratio of the rate is only the simple interest of 1*l.* for one year, at any given rate; and it is found thus: viz.

$100 : 5 :: 1 : 0.05$  = the rate at 5 per cent. per annum.

$100 : 6 :: 1 : 0.06$  = the rate at 6 per cent. &c.

Again,  $100 : 6.5 :: 1 : 0.065$  = the ratio 6 and  $\frac{1}{2}$  per cent.

And if the given time be whole years, then  $t$  = the number of those years: but if the time given be either pure parts of a year, or parts of a year mixed with years, those parts must be turned into decimals; and then  $t$  = those decimals, &c.

Now the common parts of a year may be easily turned or converted into decimal parts, if it be considered that

one  $\left\{ \begin{array}{l} \text{day is the } \frac{1}{365} \text{ part of a year} = 0.00274, \\ \text{month is the } \frac{1}{12} \text{ part of a year} = 0.08333, \\ \text{quarter is the } \frac{1}{4} \text{ part of a year} = 0.25, \\ \text{half a year} = 0.5, \text{ and three quarters} = 0.75. \end{array} \right.$

These things being premised, we may proceed to raising the theorems:

Let  $R$  = the interest of 1*l.* for one year, as before;

then  $2R$  = the interest of 1*l.* for two years,

and  $3R$  = the interest of 1*l.* for three years,

$4R$  = the interest of 1*l.* for four years; and so on for any number of years proposed.

Hence it is plain, that the simple interest of 1*l.* is a series of terms in arithmetical progression increasing, whose first term and common difference is  $R$ , and the number of all the terms is  $t$ ; therefore the last term will always be  $tR$  = the interest of 1*l.* for any given time signified by  $t$ .

Then  $\left\{ \begin{array}{l} \text{As } 1 \text{ l. is to the interest of } 1 \text{ l. so is any} \\ \text{principal, or given sum, to its interest.} \end{array} \right.$

That is,  $1 \text{ l.} : tR :: P : tRP$  = the interest of  $P$ . Then the principal being added to its interest, their sum will be  $= A$ , the amount required: which gives this general theorem:

Theorem  $tRP + P = A$ .

From whence the three following theorems are easily deduced:

Theorem 2.  $\left\{ \begin{array}{l} \frac{A}{tR+1} = P. \end{array} \right.$

Theorem 3.  $\left\{ \begin{array}{l} \frac{A-P}{tR} = R. \end{array} \right.$

Theorem 4.  $\left\{ \begin{array}{l} \frac{A-P}{R} = t. \end{array} \right.$

These four theorems resolve all questions about simple interest. Thus, if it were to be required to find what 256*l.* 10*s.* will amount to in three years, one quarter, two months, and eighteen days, at 6 per cent. per annum.

Here is given  $P = 256.5$ ,  $R = 0.06$ , and  $t = 3.46599$ . Quere  $A$ , per theorem 1.

For three years = 3.

One quarter = 0.25

Two months = 0.16667 = 0.08333  $\times$  2

Eighteen days = 0.04932 = 0.00274  $\times$  18

Hence  $t = 3.46599 \times 0.06 = 0.207594 = tR$ .

Then  $0.207594 \times 256.5 = 53.341586 = tRP$ .

And  $53.341586 + 256.5 = 309.841586 = tRP + P = A$ .

That is, 309 841586 = 309*l.* 16*s.* 10*d.* being the answer required.

And thus may all questions, relating to simple interest, be resolved, due regard being had to the theorem relating to the question.

Annuities, or pensions in arrears, may be computed by simple interest, as follows:

When annuities, payable yearly, half yearly, &c. are not paid as they become due, such annuities are said to be in arrears; and, therefore, to find the value of an annuity in arrears, we must calculate what all those payments will amount to, allowing any rate of simple interest for their forbearance, from the time each particular payment became due. In order to this, put  $u$  = the annuity,  $t$  = the time it has continued unpaid,  $R$  = the ratio, or interest for 1*l.* for one year, and  $A$  = the amount of the annuity and its interest.

Then if  $u$  = the first year's rent due with interest,  $Ru$  will = the interest, and  $2u$  = the rent due at the end of the second year; and, consequently,  $2Ru$  = the interest, and  $3u$  = the rent due at the end of the third year; and  $3Ru$  = the interest, and  $4u$  = the rent due at the end of the fourth year: and so on for any number of years.

Hence it is evident, that  $Ru + 2Ru + 3Ru + 4Ru + 5u = A$ , the sum of all their rents and interests being forborn five years: from whence it follows, that  $Ru + 2Ru + 3Ru + 4Ru = A - tu$ . Here  $t = 5$ . Divide the equation by  $u$ , and we have  $R + 2R + 3R + 4R = \frac{A - tu}{u}$ . In order to find the sum of this progression,

put  $z = R + 2R + 3R + 4R$ , &c. Then  $1 + 2 + 3 + 4$ , &c. =  $\frac{z}{R}$ . Here the sum of the first

and last terms is  $4 + 1 = 5 = t$ . And the number of all the terms is  $4 + 1 = 5 = t$ ; therefore  $\frac{t-1}{2} \times t =$

the sum of all the terms. That is,  $\frac{tt-t}{2} = \frac{z}{R}$ .

Hence  $\frac{tR-t}{2} = z$ . Consequently  $\frac{tR-t}{2} =$

$\frac{A - tu}{u}$ .

From this equation the three following theorems are easily and naturally deduced:

Theorem 1.  $\frac{tRu - Ru + 2tu}{2} = A$ . Or  $\frac{ttu - tu}{2} \times R : + tu = A$ .

Theorem 2.  $\frac{2A}{tR + tR + 2t} = u$ .

Theorem 3.  $\frac{2A - 2tu}{ttu - tu} = R$ . Let  $\frac{2}{R} = x + 1$ .

Then  $t = \sqrt{\frac{2A}{Ru} + \frac{x+1}{4}} - \frac{1}{2}x$ . Theorem 4.

By the help of these four theorems, all questions of this nature may be easily solved. Thus, for example :

Suppose 250 *l.* yearly annuity, be forborn or unpaid seven years, what will it amount to in that time at 6 per cent. for each payment as it becomes due ?

Here  $u = 250$ ,  $t = 7$ , and  $R = 0.06$ , are given, to find  $A$ ; which is easily performed by theorem 1. For, first  $250 \times 7 = 1750 = tu$ ; and  $1750 \times 7 = 12250 = t^2u$ . Again,  $12250 - 1750 = 10500 = tu$ . And  $\frac{10500}{0.06} = 315$ . Lastly,  $315 + 1750 = A = 2065$  *l.* the answer required.

Having shewn the method of finding the value of annuities in arrears, we shall proceed to explain the manner of finding the present worth of annuities, computed at simple interest.

The whole business of purchasing annuities, or taking of leases, &c. for any assigned time, depends upon the purchase, with the annuity or yearly rent, by allowing the same rate of interest to both parties, which may be easily performed by carefully attending to what has been already said. For example, What is 75 *l.* yearly rent, to continue nine years, worth in ready money at 6 per cent. per annum, simple interest ?

First, by theorem 1, find what the proposed yearly rent would amount to, if it were forborn nine years at 6 per cent. which by the said theorem will amount to  $837 = A$ .

Then find what principle, being put out to interest for the same time, and at the same rate, will amount to  $837 = A$ .

Thus  $iR = 0.54 = 9 \times 0.06$ ,  $iR + 1 = 1.54$ , by which divide 837, and we have  $543.5064 = 543$  *l.* 10 *s.* 1  $\frac{1}{2}$  *d.* the present worth of the annuity required.

**Compound INTEREST**, is that which arises from any principal and its interest put together, as the interest still becomes due; so that at every payment, or at the time when the payments become due, there is created a new principal; and for that reason it is called interest upon interest, or compound interest.

As for instance, suppose 100 *l.* were lent out for two years, at 6 per cent. per annum, compound interest; then at the end of the first year, it will only amount to 106 *l.* as in simple interest; but for the second year this 106 *l.* becomes principal, which will amount to 112 *l.* 7 *s.* 2  $\frac{1}{2}$  *d.* at the second year's end; whereas by simple interest it would have amounted to but 112 *l.* And although it be not lawful to let out money at compound interest, yet in purchasing annuities or pensions, &c. and taking leases in reversion, it is very usual to allow compound interest to the purchaser for his ready money, and therefore it is very requisite to understand it.

Let  $R$  be the amount of one pound in one year, viz. principal and interest;  $P$  any sum put out at interest for any number  $a$  of years,  $a$  its amount,

A any annuity forborn  $n$  years,  $m$  its amount, and  $v$  its worth in present money, for the same time.

Therefore, since one pound put out at interest, in the first year is increased to  $R$ , it will be as 1 to  $R$ , so is  $R$ , the sum forborn the second year, to  $R^2$ , the amount of one pound in two years; and therefore, as 1 to  $R$ , so is  $R^2$ , the sum forborn the third year, to  $R^3$ , the amount in three years; whence it appears, that  $R^n$ , or  $R$ , raised to the power whose exponent is the number of years, will be the amount of one pound in those years; but as 1 *l.* to its amount  $R^n$ , so is  $P$  to  $a$ , its amount in the same time; whence we have  $P \times R^n = a$ . And because the amount of one pound in  $n$  years is  $R^n$ , its increase in that time will be  $R^n - 1$ ; but its interest for one single year, or the annuity answering to that increase, is  $R - 1$ ; therefore, as  $R - 1$  to  $R^n - 1$ ,

so is  $A$  to  $m$ . Hence we get  $\frac{A \times R^n - 1}{R - 1} = m$ . But as it appears that one pound, ready money, is equivalent to  $R^n$ , to be received at the expiration of  $n$  years, we have, as  $R^n$  to 1, so is  $\frac{A \times R^n - 1}{R - 1}$  (the sum in arrear) to  $v$ , its present worth in ready money; whence  $\frac{A \times 1 - R^{\frac{1}{n}}}{R - 1} = v$ . From these theorems,

the various questions relating to compound interest, annuities in arrears, and purchasing of annuities, are respectively resolved.

Several ingenious mathematicians, as Dr. Halley, De Moivre, Simpson, &c. have explained the method of computing the expectation or estimate of life; we shall therefore here subjoin, a curious and useful table, that shews the value of annuities for every fifth year of age to the 75th, at 3, 4, and 5 per cent. as given by the last mentioned gentleman, in his *Doctrine of Annuities upon Lives*.

| Age | Year's purchase at 5 per cent. | Year's purchase at 4 per cent. | Year's purchase at 3 per cent. |
|-----|--------------------------------|--------------------------------|--------------------------------|
| 6   | 14.1                           | 16.2                           | 18.8                           |
| 10  | 14.3                           | 16.4                           | 19.0                           |
| 15  | 13.9                           | 15.8                           | 18.3                           |
| 20  | 13.0                           | 14.8                           | 17.2                           |
| 25  | 12.3                           | 14.0                           | 16.1                           |
| 30  | 11.6                           | 13.1                           | 15.0                           |
| 35  | 10.9                           | 12.3                           | 14.1                           |
| 40  | 10.3                           | 11.5                           | 13.2                           |
| 45  | 9.8                            | 10.8                           | 12.3                           |
| 50  | 9.2                            | 10.1                           | 11.4                           |
| 55  | 8.5                            | 9.3                            | 10.3                           |
| 60  | 7.9                            | 8.4                            | 9.2                            |
| 65  | 7.1                            | 7.5                            | 8.0                            |
| 70  | 6.2                            | 6.5                            | 6.9                            |
| 75  | 5.2                            | 5.4                            | 5.6                            |

**INTEREST**, in law, is generally taken for a chattel real, or a lease for years, &c. but more for a future term.

**INTERJECTION**, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

As the greatest part of the expressions used on these occasions are taken from nature alone, the real interjections in most languages, are monosyllables; and as all nations agree in these natural passions, so do they agree in the signs and indications of them, as of love, mirth, &c.

The Greeks confound their interjections with adverbs, and the Hebrews confound them with their adverbs and prepositions, calling them all by the general name particle.

**INTERIM**, a name given to a formulary, or kind of confession to the articles of faith, obtruded upon the protestants after Luther's death by the emperor Charles V. when he had defeated their forces; so called because it was only to take place in the interim, mean time, till a general council should have decided all points in dispute between the protestants and the Romanists.

**INTERLOCUTORY ORDER**, in law, an order that does not decide the cause, but only some matter incident thereto, which happens between the beginning and end of a cause; as when in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cause; which order, not being final, is called interlocutory.

**INTERLUDE**, an entertainment exhibited on the theatre between the acts of the play, to amuse the spectators while the actors shift their dress, or to give time of changing the scenes and decorations.

**INTERMITTENT**, or **INTERMITTING FEVERS**, such fevers as go off and soon return again, in opposition to those which are continual. See the article *Intermitting FEVER*.

**INTERNAL**, in general, denotes whatever is within a thing.

**INTERNODIUM**, among botanists, implies the space between two knots or joints of the stalks of barley, oats, and the like plants.

**INTEROSSEUS**, in anatomy, an appellation given to the muscles which move the fingers and toes, from their being situated between the bones of those parts. See the articles *MUSCLE*, *FLEXOR*, &c.

**INTERPRETATION**, among critics, denotes a spurious passage, inserted into the writings of some ancient author.

**INTERPRETER**, in general, denotes a person who explains the words or writings of another, so as to make them intelligible to those who did not understand them before.

**INTERREGNUM**, the time during which the throne is vacant, in elective kingdoms; for in such as are hereditary, like ours, there is no such thing as an interregnum.

**INTERREX**, the magistrate who governs during an interregnum.

**INTERROGATION**, or *Point of INTERROGATION*, in grammar, a character of this form (?) serving to denote a question.

**INTERROGATION**, in rhetoric, is a figure, whereby the orator proposes something by way of question; which, it must be owned, greatly enlivens the discourse.

**INTERROGATORIES**, in law, are questions wrote down, and demanded of the witnesses examined in a cause, more especially in the court of chancery.

**INTERRUPTION** denotes the same thing with disjunction in proportion, and is noted thus (::) signifying the breaking of the ratio in the middle of four discrete proportionals, as  $A : B :: C : D$ ; that is, as A to B, so is C to D.

**INTERRUPTION**, in rhetoric, when a person breaks off his discourse suddenly to shew some passion.

**INTERSECTION**, in mathematics, the cutting of a line or plane by another, or the point or line wherein two lines, or two planes, cut each other.

The word is derived from the Latin *inter*, and *seco*, to cut.

The mutual intersection of two planes in a right line. The center of a circle is in the intersection of two diameters, &c. The equinoxes happen, when the sun is in the intersections of the equator and ecliptic.

**INTERSPINALES Colli**, in anatomy, small fleshy muscles of the neck, arising from the superior parts of each double spinal process of the neck, except of the second vertebra; and inserted into the inferior parts of all the double spines. When these muscles act, they draw the spines of the vertebra of the neck nearer each other.

**INTERSTELLAR**, a word used by some authors to express those parts of the universe that are without and beyond our solar system.

**INTERTIES**, in architecture, those small pieces of timber that lie horizontally between the sommers, or between them and the fell, or reson.

**INTERTRANSVERSALES Colli**, in anatomy, certain muscles situated among the transverse apophyses of the vertebrae: they arise from the lower vertebra, and are inserted into that next above: they are of the same size and figure with the interspinales.

**INTERVAL**, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

**INTERVALS**, in gardening and husbandry, the spaces left between the several rows of plants sown or set in gardens or fields. See *HUSBANDRY*.

IN-

**INTESTATE**, in law, a person that dies without making a will; in which case, a distribution of his personal estate, after his debts and funeral charges are paid, is to be made among the wife and children of the deceased, or for want of such, among the next of kin.

**INTESTINES**, in anatomy, long, cylindrical, hollow, and membranaceous bodies; or rather, one such continued body, or tube, reaching from the stomach to the anus.

The structure and substance of the intestines are membranaceous; being formed, in every part, of five coats or tunics. The first is the common coat, from the peritonæum, and is membranaceous. The second is cellular, and is called by late writers, tunica cellulosa Ruyschii: it is contiguous with the mesentery, and is to be discovered by inflating it; this coat, in fat animals, frequently contains abundance of fat. The third is muscular; it is composed of a double series of fibres, in part longitudinal, and in part annular; and these assist the motion of the guts. The fourth coat is nervous: it is furnished with abundance of cellules, vascules, and glands, and is thicker than the others: from this arise the rugæ, and the valves of the intestines. The fifth is the villose coat, which sustains the terminations of the excretory vessels, and the beginnings of the lacteals: hence, when nicely examined, it has the appearance of a sieve: it is the organ of percolation of the chyle.

The intestines have vessels in great abundance. Their arteries are from the meseraic ones: the upper meseraic serving for the smaller intestines, the lower for the larger; and these make a multitude of very singular and surprizing anastomoses. The veins are meseraics, and go off to the vena portæ and the liver. The nerves are sent from the intercostals; and the par vagum. And besides these we are to observe the lacteal vessels. See the article **LACTEAL**.

The rectum, it is to be observed, receives blood-vessels also from the hypogastrics. There are also, besides the Brunnerian glands of the duodenum, other glands in the intestines, called from the name of the person who discovered them, glandulæ Peyerii. These, in the small guts, are usually little, congregate, and miliary; but sometimes they are single. They are larger as they are nearer to the duodenum, and smaller as they approach towards the great guts. Their office is to discharge into the intestines a liquor, which serves for the attenuation of the chyle, and for the lubricating of the intestines. In the larger guts, and in the vermiform appendage, they are single and large, of a lenticular figure; and they are largest of all in the rectum. They have mouths, out of which there is secreted a fluid, which serves to lubricate the sides of the intestines, and to soften the fæces, that they may be evacuated without pain.

The use of the smaller guts is to promote the formation of the chyle, to perfect its secretions, and to propel the remaining fæces to the larger. The office of the larger guts is to receive and collect the matter of the fæces, at a proper time to expel it. See **CHYLE**.

**INTESTINAL**, something belonging to, or seated in the intestines.

**INTRADA, ENTRY**, in the Italian music, is much the same with prelude or overture.

**INTRENCHMENT, or RETRENCHMENT**, in the art of war. See the article **RETRENCHMENT**.

**INTRIGUE, or INTREAGUE**, an assemblage of events or circumstances, occurring in an affair, and perplexing the persons concerned in it.

In this sense, it is used to signify the nodus or plot of a play or romance; or that point wherein the principal characters are most embarrassed, through the artifice and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances.

In tragedy, or an epic poem, there are always two designs; the first and principal is that of the hero of the piece. The second contains the designs of all those who oppose him: these opposite causes produce opposite effects; to wit, the efforts of the hero for the execution of his design, and the efforts of those who thwart it. As those causes and designs are the beginning of the action, so these efforts are the middle, and there form a knot or difficulty which we call the intrigue, that makes the greatest part of the poem. It lasts as long as the mind of the reader or hearer is suspended about the event of those opposite efforts: the solution or catastrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up.

**INTRINSIC**, a term applied to the inner, real, and genuine values, properties, &c. of any thing, in opposition to their extrinsic or apparent values, &c.

**INTRUSION**, in law, obtains where an ancestor dies seized of an estate or inheritance, which is expectant upon an estate for life, and the tenant for life dies; after which a stranger enters before the heir, in which case he is said to intrude.

**INTUITION**, among logicians, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case, the mind perceives the truth as the eye doth the light, only by being directed towards it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. See **IDEA**.

This part of knowledge, says Mr. Locke, is irresistible, and, like the sun-shine, forces itself immediately to be perceived as soon as ever the mind turns its view that way. It is on this intuition that all

# IN V

all the certainty and evidence of our other knowledge depends; this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater. See the articles JUDGMENT, KNOWLEDGE, DEMONSTRATION, &c.

INVALID, a person wounded, maimed, or disabled for action by age, &c.

INVECTED, in heraldry, denotes a thing fluted or furrowed.

INVECTIVE, in rhetoric, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproofed; whereas the invective is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it was directed.

INVENTION denotes the act of finding any thing new, or even the thing thus found.

INVENTION, in rhetoric, being one of the second divisions of invention, according to Bacon, signifies the finding out and choosing of arguments which the orator is to use for proving his point, or moving his hearers passions.

INVENTION, in poetry, is applied to whatever the poet adds to the history of the subject he has chosen, as well as to the new turn he gives it.

INVENTION, in painting, is the choice which the painter makes of the objects that are to enter the composition of his piece.

INVENTORY, in law, &c. is a schedule containing all the goods and chattels of a deceased person that belonged to him at the time of his death, together with the value of the same, as appraised by two or more indifferent persons.

INVERSE is applied to a manner of working the rule of three, or proportion, which seems to go backward, or contrary to the order of the common or direct rule. See the articles RULE of Three and PROPORTION.

INVERSION, in grammar, is where the words of a phrase are ranged in a manner not so natural as they might be.

It is a considerable beauty either in verse or prose, when we have it from an able hand; it gives vigour and variety to a sentence, and keeps the mind in an agreeable suspense and expectation of a marvellous turn and conclusion.

INVESTIGATION properly denotes the finding any thing out by the prints of the feet.

Mathematicians, &c. have hence applied the word to the respective researches in which they are employed.

INVESTIGATION of a Theme, in grammar, the finding out the primitive sense, mood, and person of any verb that is remote from its source.

It is absolutely necessary to be acquainted with this method of investigation, in order to understand a Greek author.

Clenard was the first who introduced the term into grammar.

# IN V

INVESTITURE, in law, a giving livery of seisin or possession.

INULA, in botany, a genus of plants whose flower is compounded and radiated; the corollæ which compose the disc are very numerous, hermaphrodite, and infundibuliform; the female flowers form the rays, and are ligulated and linear; there is no pericarpium, but the cup, which is immutable, contains solitary, quadrangular, linear seeds, placed on a plane naked receptacle.

To this genus belongs the elecampane. See the article ELECAMPANE.

INVOCATION, in theology, the act of adoring God, and especially of addressing him in prayer for his assistance and protection.

INVOCATION, in poetry, an address at the beginning of a poem, wherein the poet calls for assistance of some divinity, particularly of his muse, or the deity of poetry.

INVOICE, an account in writing of the particulars of merchandize, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country.

One copy of every invoice is to be inserted verbatim in the invoice-book, for the merchant's private use; and another copy must, immediately upon shipping off the goods, be dispatched by post, or otherwise, to the correspondent. This copy is commonly drawn out upon a sheet of large post-paper, to the end of which is subjoined a letter of advice.

INVOICE-BOOK. This book is paged, and contains copies of the invoices of goods sent to sea: for as a merchant is obliged to send his correspondent an invoice of all the goods he consigns to him, so it is reasonable that he should keep a copy of it for himself.

INVOLUCRUM, among botanists, a kind of calyx placed at the foot of an umbel at a distance from the flower, by the length of the footstalk surrounding a number of flowers, each of which having, besides this general cup, its own particular perianthium. An involucre is either universal or partial, and is generally disposed in a radiated form.

INVOLUTION, in algebra, the raising any quantity from its root to any height or power assigned.

The quantity  $a^m$  expresses any power of  $a$  in general; the exponent ( $m$ ) being undetermined; and  $a^{-m}$  expresses  $a^{\frac{1}{m}}$ , or a negative power of  $a$  of an equal exponent: and  $a^m \times a^{-m} = a^{m-m} = a^0 = 1$  is their product,  $a^n$  expresses any other power of  $a$ ;  $a^m \times a^n = a^{m+n}$  is the product of the powers  $a^m$  and  $a^n$ , and  $a^{m-n}$  is their quotient.

To raise any simple quantity to its 2d, 3d, or 4th power, is to add its exponent twice or four times to itself; therefore, the 2d power of any quantity is had by doubling its exponent, and the third by

by trebling its exponent; and in general, the power expressed by  $m$  of any quantity is had by multiplying the exponent by  $m$ , as is obvious from the multiplication of powers.

Thus, the 2d power or square of  $a$  is  $a^{2 \times 1} = a^2$ ; its third power or cube is  $a^{3 \times 1} = a^3$ ; and the  $m^{\text{th}}$  power of  $a$  is  $a^{m \times 1} = a^m$ . Also the square of  $a^4$  is  $a^{2 \times 4} = a^8$ ; the cube of  $a^4$  is  $a^{3 \times 4} = a^{12}$ ; and the  $m^{\text{th}}$  power of  $a^4$  is  $a^{4 \times m}$ . The square of  $abc$  is  $a^2 b^2 c^2$ , the cube is  $a^3 b^3 c^3$ , the  $m^{\text{th}}$  power  $a^m b^m c^m$ .

The co-efficient must also be raised to the same power by a continual multiplication of itself, as often as an unit by itself, is contained in the exponent of the power required. Thus the cube of  $3ab$  is  $3 \times 3 \times 3 \times a^3 b^3 = 27 a^3 b^3$ .

As to the signs when the quantity to be involved is positive, it is obvious that all its powers must be positive. And, when the quantity to be involved is negative, yet all its powers whose exponents are even numbers must be positive; for any number of multiplications of a negative, if the number is even, gives a positive.

The power then only can be negative, when its exponent is an odd number, though the quantity to be involved be negative.

The powers of  $-a$  are  $-a, +a^2, -a^3, +a^4, -a^5, \&c.$

Those whose exponents are 2, 4, 6, &c. are positive; but those whose exponents are 1, 3, 5, &c. are negative.

The involution of compound quantities is a more difficult operation. The powers of any binomial  $a+b$  are found by a continual multiplication of it by itself, as follows:

$$\begin{array}{l}
 a+b = \text{the root.} \\
 \times a+b \\
 \hline
 a^2+ab \\
 +ab+b^2 \\
 \hline
 a^2+2ab+b^2 = \text{the square, or 2d power.} \\
 \times a+b \\
 \hline
 a^3+2a^2b+ab^2 \\
 +a^2b+2ab^2+b^3 \\
 \hline
 a^3+3a^2b+3ab^2+b^3 \\
 \times a+b \\
 \hline
 a^4+3a^3b+3a^2b^2+ab^3 \\
 +a^3b+3a^2b^2+3ab^3+b^4 \\
 \hline
 a^4+4a^3b+6a^2b^2+4ab^3+b^4 = \text{the biquadrate or 4th power.}
 \end{array}$$

If the powers of  $a-b$  are required, they will be found the same as the preceding, only the terms in which the exponent of  $b$  is an odd number will be found negative; because an odd number of multiplications of a negative produces a negative. Thus the cube of  $a-b$  will be found to be  $a^3-3a^2b+3ab^2-b^3$ ; where the 2d and 4th terms are negative, the exponent of  $b$  being an odd number in these terms. In general, the terms of any power of  $a-b$  are positive and negative by turns.

If it be observed, that, in the first term of any power of  $a \mp b$ , the quantity  $a$  has the exponent of the power required; that, in the following terms, the exponents of  $a$  decrease gradually by the same difference (viz. an unit) and that in the last terms it is never found: the powers of  $b$  are in the contrary order; it is not found in the first term, but its exponent in the 2d term is an unit, in the 3d term its exponent is 2; and thus its exponent increases, till in the last term, it becomes equal to the exponent of the power required.

As the exponents of  $a$  thus decrease, and at the same time those of  $b$  increase, the sum of their exponents is always the same, and is equal to the exponent of the power required.

To find the co-efficient of any term, the co-efficient of the preceding term being known, you are to divide the co-efficient of the preceding term by the exponent of  $b$  in the given term, and to multiply the quotient by the exponent of  $a$  in the same term, increased by an unit.

In general, if  $a+b$  is to be raised to any power  $m$ , the terms, without their co-efficients, will be  $a^m, a^{m-1}b, a^{m-2}b^2, a^{m-3}b^3, a^{m-4}b^4, a^{m-5}b^5, \&c.$  continued till the exponent of  $b$  becomes equal to  $m$ .

The co-efficients of the respective terms, according to the last rules, will be 1,  $m, m \times \frac{m-1}{2}, m \times$

$$\begin{array}{l}
 \frac{m-1}{2} \times \frac{m-2}{3} m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4}, m \times \frac{m-1}{2} \\
 \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5}, \&c. \text{ continued until you} \\
 \text{have one co-efficient more than there are units} \\
 \text{in } m.
 \end{array}$$

JOACHIMITES, in church history, the disciples of Joachim, a Cistercian monk, who was an abbot of Flora in Calabria, and a great pretender to inspiration.

JOB, or *Book of Job*, a canonical book of the Old Testament, containing a narrative of a series of misfortunes which happened to a man whose name was Job, as a trial of his virtue and patience; together with the conferences he had with his cruel friends, on the subject of his misfortunes, and the manner in which he was restored to ease and happiness. This book is filled with those noble, bold and figurative expressions, which constitute the very soul of poetry.

Many of the Jewish rabbins pretend that this relation is altogether a fiction: others think it a simple narrative of a matter of fact, just as it happened; while a third sort of critics acknowledge that the ground-work of the story is true, but that it is wrote in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining.

The time is not set down in which Job lived. Some have thought that he was much ancients than

Moses, because the law is never cited by Job or his friends, and because it is related that Job himself offered sacrifices. Some imagine that this book was wrote by himself; others say, that Job wrote it originally in Syriac or Arabic, and that Moses translated it into Hebrew: but the rabbins generally pronounce Moses to be the author of it, and many Christian writers are of the same opinion.

**JOBBER**, in law, a person that buys and sells cattle for others. Hence stock-jobbers are persons who buy and sell stocks for other persons.

**IOGUIS**, among the East-Indians, a kind of hermits, who generally stand under trees, or near their pagods. Some of them go stark naked, holding their arms across over their heads, and continue in that posture all their lives: others lie on the ground, with one leg higher than the other, and and their arms raised above their head; and these wretched penitents insensibly lose the use of their arms and legs: some confine themselves in cages, set on the top of a thick stake, fixed in the ground, and these cages are so small, that they put the penitent to prodigious torture: some holding a sabre in one hand, and a kind of shield in the other, go up a kind of crane, where hooking themselves to an iron, which runs a considerable way into their backs, they spring forward into the air, flourishing their sabres, and launching out into extravagant praises of their idols, and others plunge into the Ganges, in hopes of being devoured by a crocodile, fancying that by this means they shall obtain the happiness of the next life.

These miserable wretches are considered by the Indians, as perfect models of piety and holiness: they are followed by persons of both sexes, who make a vow of devoting themselves to their service, and are wholly employed in soothing their voluntary sufferings by offering them alms and refreshments. They call the pious to their devotions by ringing a little bell; and when they hold their spiritual conversations, they sit close in a ring, and set up a banner made of several pieces of stuff fastened at the end of a stick,

**JOHN**, or *Gospel of St. JOHN*, a canonical book of the New Testament, containing a recital of the life, actions, doctrine and death of our Saviour Jesus Christ, written by St. John the apostle and evangelist. See the article **GOSPEL**.

St. John wrote his gospel at Ephesus, after his return from the Isle of Patmos, at the desire of the christians of Asia. St. Jerom says, he would not undertake it, but on condition they should appoint a public fast, to implore the assistance of God, and that fast being ended, St. John, filled with the Holy Ghost, broke out into these words. "In the beginning was the word," &c. The ancients assign two reasons for this undertaking: the first is, because in the other three gospels, there was wanting the history of the beginning of Jesus

Christ's preaching, till the imprisonment of John the Baptist, which, therefore, he applied himself particularly to relate. The second reason was in order to remove the errors of the Corinthians, Ebionites, and other sects.

**St. JOHN'S Day**, the name of two Christian festivals, one observed on the 24th of June, kept in commemoration of the wonderful circumstances attending the birth of St. John the Baptist; and the other on the 27th of December, in honour of St. John the Evangelist.

**St. JOHN'S WORT**, a plant called by authors hypericum. See **HYPERICUM**.

**JOINDER**, or **JOYNDER**, in law, signifies the joining of two persons in one suit against another; as for instance, if there are two joint-possessors of goods, and these are taken from one of them, they may both join in an action to recover them.

**JOINERY**, the art of working in wood, or of fitting various pieces of timber together.

**JOINT**, in general, denotes the juncture of two or more things.

The joints of the human body are called by anatomists articulations. See **ARTICULATION**.

The term joint is also applied to the separation between the stones or bricks of a building, usually filled with mortar, plaster, or cement; also by carpenters, to the several manners of assembling or fitting pieces of wood together, as a dove-tail joint, &c.

*Stiffness of the JOINTS*, in surgery and medicine, sometimes proceeds from the bones being broken, bruised, or wounded, especially about the extreme parts, which being kept in one posture, in order for cure, the synovia of the joints becomes thick, and depraves or quite abolishes its motion; or it may proceed from the bony juice proceeding from broken bones, and insinuating itself into the joint. Hoffman says, diseases of the joints sometimes proceed from spasms of the ligament.

**JOINT-EXECUTORS**, in law, are when two or more persons are appointed such by will; in which case they are accounted but as one single person; so that the actions done by one of them are taken to be the acts of all, because they all represent the person of the testator.

**JOINT LIVES**, in law, is where any thing is granted or given to two or more during their lives.

**JOINT-TENANTS** are such as hold lands or tenements jointly by one title; as were a man grants lands, &c. to persons and their heirs; such persons, during their joint tenancy must jointly plead as well as be jointly sued, which is common to them with coparceners of lands.

**JOINTURE**, in law, generally implies a settlement of lands and tenements made on a woman in consideration of marriage.

It also signifies a covenant, by which the husband, or some friends of his, assures lands, &c. to his wife, for the term of her life. **JOINTURESS**

also in Spain, but it does not appear that any labdanum is brought from thence.

Two sorts of this resin are met with in the shops. The best, though very rare, is in dark-coloured black masses, of the consistence of a soft plaster, growing still softer on being handled: the other is in long rolls coiled up, much harder than the preceding, and not so dark. The first has commonly a small, and the last a very large admixture of fine sand, which in the labdanum examined by the French academy, amounted to three fourths of the mass. It is scarcely indeed to be collected pure, independently of designed abuses; the dust blown on the plant by winds from the loose sands among which it grows, being retained by the tenacious juice.

Labdanum has been sometimes exhibited as a resinous corroborant and restringent, but principally employed in external application and perfumes: the soft kind makes an useful ingredient in the cephalic and stomachic plasters of the shops. This sort has a very agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker; and the common means of purifying these kinds of substances, though they separate the sandy matter mixed with it, render it weaker still.

**LABEL**, in heraldry, a fillet usually placed in the middle along the chief of the coat, without touching its extremities. Its breadth ought to be a ninth part of the chief. It is adorned with pendants; and when there are above three of these, the number must be specified in blazoning.

This is a kind of addition to the arms of a second brother, to distinguish him from the first, and is esteemed the most honourable of all differences.

**LABEL**, in law, a narrow slip of parchment hanging from a deed, writ, or other writing, in order to hold the appending seal.

**LABEL** of a *Circumferentor*, a long thin brass-ruler, with a sight at one end, and a center-hole at the other; chiefly used with a tangent line, to take altitudes.

**LABIA**, the lips, in anatomy. See the article **LIPS**.

**LABIAL LETTERS**, those pronounced chiefly by means of the lips. See **LETTER**.

**LABIATED FLOWERS**, monopetalous flowers, consisting of a narrow tube, with a wide mouth, divided into two or more lips. See **BOTANY** and **FLOWERS**.

**LABORATORY**, or **ELABORATORY**. See **ELABORATORY**.

**LABOUR**, in general, denotes a close application to work or business. Among seamen, a ship is said to be in labour when she rolls and tumbles very much, either a-hull, under sail, or at anchor. It is also spoke of a woman in travel, or child-birth. See **DELIVERY**.

**LABOURING**, in the marine, a violent rolling or pitching, so as to endanger the masts and hull,

by carrying away or springing the former, and straining the latter, so as to occasion a leak or other disaster.

**LABYRINTH**, in anatomy, the internal cavity of the ear, so called from its sinuosities and windings. See the article **EAR**.

**LABYRINTH**, in gardening, a winding, mazy, and intricate turning to and fro, through a wilderness, or a wood.

**LAC**, **MILK**, among physicians, &c. See the article **MILK**.

**LACCA**, **LAC**, or **STICK-LAC**, improperly called gum-lac, in natural history, a concrete brittle substance, of a dark red colour; brought from the East-Indies incruusted on pieces of sticks; internally divided into several cells; said to be the resinous juice of certain trees, collected by winged red insects of the ant kind, impregnated with the tinging matter of the insects, and by them deposited either on the branches of the trees, or on sticks fastened in the earth for that purpose. In the cells are often observed small red bodies, which appear to be the young insects.

The tinging red animal matter of the stick-lac dissolves both in water and rectified spirit, and appears to be of the same general nature with that of cochineal; like which it is made dull by alkalies, and brighter by acids, and turned to a scarlet by a solution of tin.

**Seed LAC**.—If the lac be broken in small pieces, or grains, and infused in warm liquor, the remainder will appear of a transparent yellowish or brownish colour, and, on raising the heat so as to make the water boil, melts and rises to the surface, and is thence called shell-lac.

**Artificial LACCA**, or **LAKE**, in painting, a white earthy body, as cuttle-fish bone, the basis of alum, or chalk, tinged with some crimson vegetable dye, such as is obtained from cochineal or Brasil-wood, dissolved or taken up by means of some alkaline salt, and precipitated on the earth by the addition of some acid.

Lake is used in all kinds of painting, except enamel; but particularly in oil, where it supplies the place of carmine. It is valuable both for its brightness and crimson tint; which make it useful for carnations to the portrait painters; for skies to the landscape or ship painters; and for flowers to those who paint still life. Its transparency in oil renders it also of great service in glazing, as it is called, over vermilion; and in painting scarlet draperies, and the red parts of the lips; and its acquiring a dark hue, by this transparency, when used without the addition of any opaque pigment, which gives it an unrivalled excellence in the shades of red draperies, or other similar cases. Notwithstanding these qualities, lake is not at present universally approved; nor without reason; for there is a defect which makes it to be frequently rejected, where its use can be

be avoided. This defect is the uncertainty of its standing, when prepared in that manner which most conduces to its perfection in other respects: for though some parcels will hold their colour entirely well, yet others prepared in the same manner, as far as art can assure it, will fly in a degree that makes the use of it destructive to any painting: and if this defect be effectually remedied, as it may be by securing the tinging particles by gums, from all attacks of the air; yet this is generally at the expence of the brightness and transparency; the earth, which is the basis of the pigment, being locked up by the gums, and rendered incapable of being combined intimately with, or imbibing the oil. Besides the perfections of lake, which it may have in common with other colours, there is yet another that relates only to itself, which is the inclining to the scarlet hue, that makes it more valuable for almost all the purposes to which it is applied; and where this quality, joined to the others, happens to be found in it, there is scarcely any limits to be set on its value with eminent painters of any kind.

Lake was most probably first made from the colour found in the grains of the stick-lac, from whence it seems to have taken its name; but it may be made from a great variety of substances which afford a crimson tinge; though at present it is seldom prepared from any other than cochineal, scarlet rags, and Brasil-wood.

The best of what is commonly sold is made from the colour extracted from scarlet rags, and deposited on the cuttle-bone, which may be done in the following manner:

“Take a pound of the best pearl-ashes, and having dissolved them in two quarts of water, purify them by filtering through paper. Add then to this solution two more quarts of water; and having put in a pound of scarlet shreds, procured from the taylor, for they must be entirely clean, boil them in a pewter boiler made for that purpose, till the shreds appear to have wholly lost their scarlet colour. Take them out of the solution, and press them well; dipping them after in water, and pressing them again, that all the fluid they had imbibed may be got from them, which must be put back to the rest. Take then another pound of the shreds, and repeat the like treatment of them in the same solution; as also a third and fourth pound. While this is doing, dissolve a pound and half of cuttle-fish in a pound of strong aqua-fortis, in a glass receiver, adding more of the bone, if it appear to produce any ebullition in the aqua-fortis; and having strained off this solution through flannel, pour it into the other by degrees; observing whether it produces any effervescence on putting in the last quantity; which if it do in any great degree, more of the cuttle-fish bone must be dissolved in aqua-fortis; and the solution very gradually added, till no ebullition appear to be raised by it in the mixture. If this be pro-

perly managed, the fluid will soon become clear and colourless, and the tinging particles extracted from the shreds, together with the cuttle-fish bone, will subside to the bottom, and form a crimson sediment, which is the lake. The water must then be poured off; and two gallons of hard spring-water must be put to the lake, and well stirred about to mix them; which, being likewise poured off, after the lake has again settled to the bottom, must be replaced by another two gallons; and the same method must be repeated four or five times; but if hard water cannot be procured, or the lake appear too purple, half an ounce of allum should be added to each quantity of water before it be used. When the lake is thus sufficiently freed from the salts, it must have the water drained from it in a filter, covered with a linen cloth, which has been so worn as to have no knap or down remaining on its surface. After the lake has drawn to a proper dryness, it must be dropped, on clean boards, by means of sticks of elder, mountain-ash, or other hollow wood, cut into the form of pens, and suffered to dry; when the drops will appear in the form of little cones or pyramids.”

If this lake be of a deeper colour than be desired, the proportion of scarlet shreds may be diminished; or if it be wanted yet deeper, they may be increased.

This lake, when the process succeeds well, will be very bright; and will stand equally to any whatever: but it is not so transparent and fit for glazing as that where earth of alum is the basis.

*Orange LAKE.*—This lake is the tinging part of annatto precipitated together with earth of alum. It is of a very bright orange colour, and would work well with either oil or water, but cannot be depended upon, when used either of those ways, for standing long. It is, however, a very fine colour for varnish painting, where the fear of flying is out of question; and is also of an admirable good effect for putting under crystal for the imitation of the vinegar garnet; for which purpose it has been used with great success.

The manner of preparing this lake is as follows:

“Take of the best annatto four ounces, and of pearl-ashes one pound. Put them together into a gallon of water, and boil them half an hour; and then strain the solution through paper.—Make, in the mean time, a solution of a pound and a half of alum, in another gallon of water: and mix it gradually with the solution of the pearl-ashes and annatto; observing to cease any farther addition when the fluid becomes colourless, and no further ebullition ensues on the commixture. Treat the sediment or precipitated matter, then, in the same manner as has been before directed for other kinds of lake; only this need not be formed into drops, but may be dried in square bits or round lozenges.

*LACHRYMAL*, in anatomy, an appellation given

## L A D

given to several parts of the eye, from their serving to secrete the tears.

The lachrymal gland is situated in the orbit above the smaller angle, and its excretory ducts under the upper eye-lid: these are much more easily demonstrated in the eye of an ox, than in a human one.

The lachrymal caruncle is situated in the larger angle, or canthus, serving to direct the tears to the two puncta lachrymalia; which are situated in the same angle, at the extremities of the tarfi or cartilages, and terminate in the lachrymal sacculus, the nasal canal, and in the nose itself. See the article **EYE**.

**LACHRYMALIS FISTULA**, in surgery and medicine. See **FISTULA**.

**LACHRYMATORY**, in antiquity, a vessel wherein were collected the tears of a deceased person's friends, and preserved along with the ashes and urn.

**LACONISM**, *λακωνισμος*, in matters of style, a short, pithy observation or saying; so called from the Lacedæmonians, who were remarkable for the conciseness of their discourse. See **STYLE**.

**LACTEA**, or **VIA LACTEA**, the same with galaxy. See **GALAXY**.

**LACTEAL VESSELS**, in anatomy, long slender tubes for the conveyance of the chyle from the intestines to the common reservoir. See the article **CHYLE**.

**LACTIFEROUS PLANTS**, in botany, such plants as abound with a milky juice, as the lithymalus, fenchus, and lettuce.

**LACUNÆ**, in anatomy, certain oscula or orifices, proceeding from the glandulæ substatæ in the vagina, and often so large as to admit a bristle. Their use is to secrete a fluid for lubricating the vagina, and stimulating to venery.

**LACUNAR**, in architecture, an arched roof or ceiling, more especially the planking or flooring above porticos and piazzas.

**LADANUM**, or **LABDANUM**, in pharmacy. See the article **LABDANUM**.

**LADY'S BEDSTRAW**, a plant called by botanists gallium. See **GALLIUM**.

**LADY'S COMB**, a plant otherwise called scandix. See the article **SCANDIX**.

**LADY'S FINGER**, a species of vulneraria. See the article **VULNERARIA**.

**LADY'S MANTLE**, the English name of alchimilla. See **ALCHIMILLA**.

**LADY'S SMOCK**, the English name of cardamine. See **CARDAMINE**.

**LADY'S SLIPPER**, the English name of the cypripedium. See **CYPRIPEDIUM**.

**LADY'S TRACES**, a name by which some call orchis. See **ORCHIS**.

**LADY-DAY**, in law, the 25th of March, being

## L A K

the annunciation of the holy virgin. See the article **ANNUNCIATION**.

**LAGOECIA**, round-headed cummin, in botany, a genus of plants, the flower of which consists of five petals, very short, and bicornate: there is no pericarpium, the seed, which is single, being contained in the cup.

This plant has neither the smell, appearance, or taste of cummin; its smell being more like that of the carrot.

**LAGOPHTHALMIA**, in surgery, an eversion and gaping of the eye-lids, otherwise called ectropium. See the article **ECTROPIUM**.

**LAIR**, among sportsmen, the place where the deer harbour by day. This term is also used to signify a place where cattle usually rest under some shelter: by which means the ground generally becomes enriched with their dung.

**LAKE**, a collection of waters contained in some cavity in an inland place, of a large extent, surrounded with land, and having no communication with the ocean.

Lakes may be divided into four kinds. 1. Such as neither receive nor send forth rivers. 2. Such as emit rivers, without receiving any. 3. Such as receive rivers, with emitting any. And, 4. Such as both receive and send forth rivers.

Of the first kind, some are temporary, and others perennial: most of those that are temporary owe their origin to the rain, and the cavity or depression of the place in which they are lodged: thus in India there are several such lakes made by the industry of the natives, of which some are a mile, and some two in circuit; these are surrounded with a stone wall, and being filled in the rainy months, supply the inhabitants in dry seasons, who live at a great distance from springs or rivers. There are also several of this kind formed by the inundations of the Nile and the Niger; and in Muscovy, Finland, and Lapland, there are many lakes formed, partly by the rains and partly by the melting of the ice and snow; but most of the perennial lakes, which neither receive nor emit rivers, probably owe their rise to springs at the bottom, by which they are constantly supplied.

The second kind of lakes, which emit, without receiving rivers, is very numerous. Many rivers flow from these as out of cisterns; where their springs being situated low within a hollow place, first fill the cavity, and make it a lake, which not being capacious enough to hold all the water, it overflows and forms a river: of this kind is the Wolga, at the head of the river Wolga; the lake Odium, at the head of the Tanais; the Adac, from whence one branch of the river Tigris flows; the Ozero, or White Lake, in Muscovy, is the source of the river Shackfna. The great lake Chaamay, which emits four very large rivers, which water the

COUN-

countries of Siam, Pegu, &c. the Menau, the Afa, the Caipoumo, and the Laquia, &c.

The third species of lakes, which receive rivers, but emit none, apparently owe their origin to those rivers, which in their progress from their source, falling into some extensive cavity, are collected together; and form a lake of such dimensions, as may lose as much by exhalation, as it continually receives from these sources: of this kind is that great lake improperly called the Caspian sea; the lake Asphaltites, also called the Dead sea; the lake of Geneva, and several others.

Of the fourth species, which both receive and emit rivers, we reckon three kinds, as the quantity they emit is greater, equal, or less than they receive. If it be greater, it is plain that they must be supplied by springs at the bottom; if less, the surplus of the water is probably spent in exhalations; and if it be equal, their springs just supply what is evaporated by the sun,

Lakes are also divided into those of fresh water, and those of salt. Dr. Halley is of opinion, that all great perennial lakes are saline, either in a greater or less degree; and that this saltness increases with time: and on this foundation he proposes a method for determining the age of the world.

Large lakes answer the most valuable purposes in the northern regions, the warm vapours that arise from them moderating the pinching cold of those climates; and what is still a greater advantage, when they are placed in warmer climates at a great distance from the sea, the exhalations raised from them by the sun, cause the countries that border upon them to be refreshed with frequent showers, and consequently prevent their being barren deserts.

LAMA, the sovereign pontiff, or rather god, of the Asiatic Tartars, inhabiting the country of Barantola. The lama is not only adored by the inhabitants of the country, but also by the kings of Tartary, who send him rich presents, and go in pilgrimage to pay him adoration, calling him *Lama Congiu*, i. e. God the everlasting father of heaven. He is never to be seen but in a secret place of his palace, amidst a great number of lamps, sitting cross-legged upon a cushion, and adorned all over with gold and precious stones; where, at a distance, they prostrate themselves before him, it not being lawful for any to kiss even his feet. He is called the great lama, or lama of lamas, that is priest of priests. And to persuade the people that he is immortal, the inferior priests, when he dies, substitute another in his stead, and so continue the cheat from generation to generation. These priests persuade the people, that the lama was raised from death many hundred years ago, that he has lived ever since, and will continue to live for ever.

LAMB, in zoology, the young of the sheep-kind. See the article SHEEP.

LAMENTATIONS, a canonical book of the Old Testament, written by the prophet Jeremiah. The two first chapters of this book are employed in describing the calamities of the siege of Jerusalem. In the third, the author deplors the persecutions he himself had suffered. The fourth turns upon the desolation of the city and temple, and the misfortune of Zedekiah. The fifth chapter is a prayer for the Jews in their dispersion and captivity; and at the end of all, he speaks of the cruelty of the Edomites, who had insulted Jerusalem in her misery. The four first chapters of the Lamentations are an abecedary, every verse or couplet beginning with one of the letters of the Hebrew alphabet, in the alphabetical order. The subject is of the most moving kind, and the style throughout lively, pathetic, and affecting. "Did we ever find, says Dr. South, sorrow flowing forth in such a natural prevailing pathos, as in the Lamentations of Jeremy? One would think, that every letter was wrote with a tear; that every word was the noise of a breaking heart; that the author was a man compacted of sorrows, disciplined to grief from his infancy; one who never breathed but in sighs, nor spoke but in a groan."

LAMIÆ, in heathen mythology, a kind of dæmons, in the form of women, said to have devoured children. See DÆMON.

LAMINÆ, in physiology, the thin plates whereof many substances consist.

LAMIUM, dead nettle, in botany, a genus of plants, the flower of which consists of one labiated and ringent petal: the seeds are four, triangular, and contained in the bottom of the cup.

The flowers of this plant are said to be good in the fluor albus dysentery, and scrophulous disorders. The herb is aperient, emollient, and vulnerary.

LAMMAS-DAY, a festival celebrated on the first of August by the Romish church, in memory of St. Peter's imprisonment.

LAMP, *λαμπάς*, a vessel containing oil, with a lighted wick. See OIL, FLAME, FIRE, &c.

LAMPADARY, an officer in the ancient church of Constantinople, so called from his employment, which was to take care of the lamps, and to carry a taper before the emperor or patriarch when they went to church, or in procession.

LAMPAS, LAMPERS, or LAMPRESS, among farriers, a swelling and inflammation in the roof of a horse's mouth, so called because it is cured by burning with a lamp or hot iron, in which operation great care should be taken not to touch the bone.

LAMPERN, in ichthyology, a species of petromyzon, with a single row of little teeth in the verge of the mouth, beside the lower large ones.

It grows to about a foot long, though most of those usually caught are under that standard. See the article *PETROMYZON*.

**LAMPREY**, *Lampetra*, another species of petromyzon, with about twenty rows of teeth. It grows to two feet and a half, or more, in length. It is caught in some large rivers near the sea, but is much less frequent than the former species.

**LANCEOLATED LEAF**, one resembling a spear's point.

**LANCET**, a surgical instrument, sharp-pointed, and two edged, chiefly used for opening veins in the operation of phlebotomy, or bleeding; also for laying open abscesses, tumors, &c.

**LAND**, in a limited sense, denotes arable ground. See the articles *EARTH*, *SOIL*, and *HUSBANDRY*.

It is also used for meadow-ground, pasture, wood, commons, &c. See the articles *MEADOW*, *PASTURE*, &c.

**LANDSKIP**, or **LANDSCAPE**, in painting, the view or prospect of a country, extended as far as the eye will reach.

**LANGUAGE**, an assemblage of expressions among any people, whereby to communicate their thoughts to each other. And this, change or caprice has established at first; so that usage is the rule of a language, nor has reason any thing to do therein, unless to study or teach it, such as it is. Here then commences grammar, which only furnishes reflections, called rules, to which the manners of speaking, used in that language, may be reduced.

Usage may be divided into good and bad. The difference between these is, that the one is better established than the other. In dead languages, that which makes the good usage, is the writings of the best authors in that language; and those authors are allowed the best, who wrote when the state was in its greatest glory. Thus the age of Augustus being the most distinguished period in the Roman history, we call that good Latin which is conformable to the manners of speaking used by authors who wrote within fifty years before, or after the reign of that emperor. As to the living languages, the good usage, or mode, is that which obtains amongst the most eminent persons, whether as to quality and authority, or as to learning, and the reputation of writing well.

There is found a constant resemblance between the genius of each people, and the language they speak. Thus the Greeks, a polite but voluptuous people, had a language perfectly suitable, full of delicacy and sweetness. The Romans, who seemed only born to command, had a language noble, nervous, and august; and their descendants, the Italians, are sunk into softness and effeminacy, which is as easily perceivable in their language, as in their manners. The language of the Spaniards is full of that haughtiness which constitutes the distinguishing

character of the people. The French, who have a world of vivacity, have a language that runs extremely brisk and lively. And the English, who are naturally blunt, thoughtful, and of few words, have a language exceeding short, concise, and sententious. See the articles *GREEK*, *LATIN*, *ITALIAN*, *SPANISH*, *FRENCH*, and *ENGLISH*.

The diversity of languages is generally allowed to have taken its rise from the confusion at the Tower of Babel, both by Jews, Christians, and Mahometans; but the manner in which this diversity was effected, is still in dispute among the learned.

As to the point of antiquity and priority among languages, that too has been extremely controverted. The Egyptians and Phrygians disputed concerning the antiquity of their languages: the Arabs dispute the point of antiquity with the Jews; but these, jealous even to excess of the honour of their nation, positively insist that the Hebrew tongue, such as is found in the Holy Scriptures, is the primitive language, and that spoken by the first man; while others contend that the Hebrew, Chaldee, and Arabic, are only dialects of the original tongue: however that be, the Arabic is held to be the most copious of all languages. See the articles *ARABIC*, *CHALDEE*, *HEBREW*, *EGYPTIAN*, and *PHRYGIAN*, &c.

Languages are divided into 1. Original, or mother tongues, as the Hebrew and Arabic in the east (Kircher adds the Coptic); the Teutonic and Slavonic in the west. And Du Jon maintains the Gothic to be the mother of the Teutonic tongues, namely, those spoken in the north; and some add the Biscayan or Bas-Briton, as the mother tongue of the Celtæ or Gauls.

2. Derivative languages, which are those formed out of a mixture of several others, as French, Latin, &c.

Learned, or dead languages, are those which only subsist in books, and which must be learned by the rules of grammar, as the Greek, Hebrew, Syriac, and Chaldee.

Living languages are those still spoken in some country, or other, and which may be learned by conversation. The most popular among these are the French, Italian, Spanish, and English.

Speech is a privilege peculiar to man, and he is likewise furnished with organs proper for forming an articulate voice: hence it is easy to conceive, men might form a settled and uniform language, by only affixing an idea to a word, and making others acquainted with it. And it is also easy to conceive, that the connection betwixt most words and things being perfectly arbitrary, they may be changed at different places, at different times, and by different persons. And it is not very unlikely, that variety of capacities and inclinations, the different occasions people have to express themselves, different terms of imagination, the ease people find in delivering themselves

selves rather one way than another, the forgetting old words, the many new things met with requiring new names, strangers settling among natives, &c. it is not unlikely, that these, and many other causes, should occasion an alteration in living languages.

When all mankind inhabited the same country, and kept up a commerce with each other, living through many ages, it is no great wonder that the common language was continued amongst them, without any considerable alterations, till after the flood; since Noah himself was born not long after Adam's death, and a great many antediluvians living in Noah's time might have conversed with Adam and Eve some hundred years. Since all the world was then destroyed, except Noah and his family, the tongue spoken by this patriarch must be the only remaining language, and which might be easily handed down to his posterity, as long as they dwelt in the same country. But when, before their parting, they attempted to build a city and tower, God confounded their language, inasmuch, that not being able to understand each other, they were forced to separate, and leave the building unfinished.

LANGUED, in heraldry, is applied to such animals whose tongues appear out of their mouths, being of a different colour from that of the body.

LANGUOR, a faintness or relaxation of the members, owing either to a want or decay of spirits.

LANIGEROUS, among herbalists, trees that bear such a woolly or downy substance as is commonly contained in the katkins of the willow, &c.

The word is derived from the Latin, *lana*, wool, and *gero*, to bear.

LANIUS, the butcher-bird, in ornithology, a species of falcon, with black legs, a grey back, and variegated belly.

LANNAR, or LANNERET, the blue-legged falcon, with oblong black and white spots. It is a very beautiful bird, about the size of a common crow, very bold, and usually kept for the diversion of hawking.

LANTANA, in botany, a genus of didynamious plants whose flower is monopetalous, with a cylindraceous tube and a plane quadrifid limb; the stamina are four very small filaments, topped with roundish antheræ: the fruit is a roundish unilocular drupe, which includes a bilocular nut, containing two oblong kernels.

LANTERN, or LANTHORN, a well known invention for shewing light in the night.

The word is derived from the French *lanterne*, which signifies the same thing.

LANTERN, in architecture, a little dome raised over the roof of a building, to give light, and serves as a crowning to the fabric.

LANTERNISTS, a denomination assumed by the academicians of Thoulouse.

LANUGO, the soft down of plants like that

growing on the fruit of a peach-tree; whence such plants are termed lanuginous.

LAPATHUM, the dock, in botany, a perennial plant bearing numerous imperfect flowers set in double cups; the outermost of which consists of three small green leaves, the inner of three larger reddish ones, which become a covering to a glossy triangular seed.

LAPATHUM *acutum folio plano*, sharp-pointed wild dock, with long, narrow, acuminate leaves, not curled about the edges, and the seed-covers indented and marked with little tubercles. The roots are of a brownish colour on the outside, and of a yellowish within, which grows deeper in drying.

The roots of the sharp-pointed dock have a bitterish astringent taste, and no remarkable smell: the roots of the other common wild docks are nearly of the same quality, equally discover their astringent matter both to the taste and by striking an inky blackness with a solution of chalybeate vitriol, and have been often substituted in our markets for those of the sharp-pointed kind; which last are generally, and so far as can be judged from their taste, justly accounted the most efficacious. They are supposed to have an aperient and laxative, as well as an astringent and corroborating virtue; approaching in this respect to rhubarb, but differing widely in degree, their stypticity being greater, and their purgative quality, if really they have any purgative quality at all, far less. They stand recommended in habitual costiveness, obstructions of the viscera, scorbutic and cutaneous maladies: in which last intention, fomentations, cataplasms, or unguents of the roots have been commonly joined to their internal use: in many cases, the external application alone is said to be sufficient. A decoction of half an ounce, or an ounce, of the fresh roots, or of a dram or two of the dry roots, is commonly directed for a dose.

LAPATHUM *rhabarbarum monachorum*, monks rhubarb, garden patience, with large, broad, acuminate leaves; reddish branched stalks; the leaves that cover the seeds unindented, and a tubercle on one of them: the root is of a yellow colour, with red veins, approaching in appearance to rhubarb.

This root is supposed to possess the virtues of rhubarb in an inferior degree. It is obviously more astringent than rhubarb, but comes very far short of it in purgative virtue, though given, as usually directed in double its dose; nauseating the stomach, without producing any considerable evacuation. It communicates a deep yellow tincture both to water and spirit.

LAPIDARY, an artificer who cuts precious stones. See the articles GEM and DIAMOND.

LAPIDARY STYLE, denotes the style proper for monumental or other inscriptions; being a sort of medium between prose and verse. The jejune and brilliant are equally to be avoided.

**LAPIDESCENT**, that which has the faculty of turning bodies to a stony nature.

**LAPIS**, in general, is used to denote a stone of any kind. See **STONE**.

**LAPPA**, burdock, in Tournefort's system, the same with the *arctium* of Linnaeus. See the article **ARCTIUM**.

**LAPSA**, denotes a patron's neglect or omission to present to a church within six months after it becomes vacant. When, after a vacancy, the patron does not present in six months, the ordinary has the next six months to collate to the benefice; and if he does not present within that time, the metropolitan has farther six months to do it in; and if he should fail in doing it in his time, the next six months devolve to the crown.

**LAPSANA**, nipplewort, in botany, a genus of plants whose flower is compound, imbricated, and uniform; consisting of a number of hermaphrodite florets, each of which are monopetalous, ligulated, and quinque-dentate: it hath no pericarpium; but the seeds, which are solitary, oblong, and three cornered, are placed in the squamæ of the calyx.

**LAQUEUS**, in surgery, a kind of ligature so contrived, that when stretched by any weight, or the like, it draws up close. Its use is to extend broken or disjointed bones, to keep them in their places when they are set, and to bind the parts close together.

**LARCENY**, in law, a felonious carrying away another person's goods; and this, according to the value of the things stolen, is either grand or petit larceny; the first being stealing effects above the value of 1*s.* and the last such as are either of that value, or under it: but where two persons together steal goods to the value of only 13*d.* it is grand larceny in both; and if one person, at different times, steal several different things from the same person, which amount upon the whole to above 12*d.* value, they may be joined in one indictment, and the offender found guilty of grand larceny; but this is very seldom practised; on the contrary, the jury, where the theft appears to be the first offence, frequently bring in their verdict as they lawfully may, that the things are not above 10*d.* value, and by that means reduce the offence to petit larceny, though the offender may perhaps be indicted for stealing to the value of 30 or 40*s.* and upwards. The crime of grand larceny is punishable with death, and that of petit larceny, only with the corporal punishment of whipping, &c.

**LARES**, certain inferior deities among the ancient Romans, who were the guardians of houses; they were also sometimes taken for the guardians of streets and ways, and Tibullus makes them the guardians of the fields.

**LARGO**, in the Italian music, a slow movement, one degree quicker than the grave, and two

than the adagio. See the articles **ADAGIO** and **GRAVE**.

**LARIX**, the Larch-tree, in botany, a genus of trees, whose leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote distances from the male flowers on the same tree: the male flowers are very like small cones at their first appearance, but afterwards stretched out in length.

These trees are propagated by seeds, which should be sown in the beginning of March, upon a bed of light soil, exposed only to the morning sun: or otherwise it may be sown in pots or boxes of light earth, and placed near a hedge, where they may have the morning sun only. The seed should be covered about half an inch thick with fine light earth, and in very dry weather should be gently refreshed with water. In about six weeks, if your seeds were good, your plants will come up, at which time you should carefully guard them against the rapacious birds, which would otherwise pull off the heads of the plants, as they thrust themselves out of the ground with their covers on them: and observe to refresh them with water in dry weather, especially if they are sown in pots or boxes; as also to keep them clear from weeds, which, if suffered to grow among the young plants, will soon destroy them: nor should they be too much exposed to the sun, or strong winds; both which are very injurious to these plants while they are young: but in October you should, if they are in boxes or pots, remove them into a situation where they may be defended from sharp winds, which are sometimes hurtful to them, while young; but afterwards they will endure the severest weather of our climate.

These trees are very proper for the sides of barren hills, where few other sorts will thrive so well; nor is this tree very delicate in its soil, but will grow much better on poor, strong, stony land, than in rich ground; and, during the summer, they appear very beautiful; but in autumn they cast their leaves, whereby some people have been deceived, by supposing them dead, and have destroyed them.

From the wounded bark of this tree exudes the purest Venice turpentine; and on the body and branches of it grows the agaric, which is a drug used in medicine.

**LARK**, *Alauda*, in ornithology, a distinct genus of birds; the characters of which are these: the tongue, which is membranaceous and pointed, has a rim or margin round it; the beak is straight and pointed; the two chaps equal in size; and the claw of the hinder toe longer than any of the other toes.

To this genus belong, 1. The sky-lark, with the long winged feathers, variegated with white and brown. 2. The tit-lark, with a white line over the eyes. 3. The wood-lark, with the wings obliquely variegated with white. 4. The yellow-breasted

breasted lark. 5. The snow-bird, or pied chaf-finch, with the tail-feathers black, except the three lateral ones, which are white.

LARK-SPUR, delphinium, in botany. See the article DELPHINIUM.

LARMIER, in architecture, a flat square massive member of the cornice, between the cymatium and ovolo.

The word is derived from the French *larmæ*, a tear, as it causes the rain-water to fall at a distance from the wall drop by drop like tears. See CORNICHE.

LARUS, the gull, in ornithology, a genus of the anseres order of birds, thus characterized: the beak is straight all the way, except just at the point, where it turns down; add to this, that it is obtuse, not denticulated along the sides, and its lower chap gibbous or protuberant underneath.

LARINGOTOMY, or BRONCHOTOMY. See the article BRONCHOTOMY.

LARYNX, in anatomy, forms the protuberance in the upper and anterior part of the neck, called pomum Adami: it is termed the head of the trachea arteria, being more prominent in men than in women. It principally consists of five cartilages, as the cartilago thyroïdes, cricoides, two arytenoides, and the epiglottis; they are connected together by ligaments, and have muscles, glands, and membranes belonging to them.

LASERPITIUM, laserwort, in botany, a genus of umbelliferous plants; the general umbel is uniform; the proper flowers consist each of five equal petals inflexo-cordated at the ends; there is no pericarpium. The fruit is oblong, and separable into two parts, and is ridged with eight longitudinal membranes: the seeds are two in number, very large, oblong, and semi-cylindric, plane on one side, but on the other ornamented on the back and edges with four membranes.

All the species of laserwort, if wounded, drop a very acrid juice, which turns to a resinous gummy substance, very acrimonious. This was externally applied by the antients to take away black and blue spots that came by bruises or blows, as also to take away excrescences; and was sometimes prescribed by some internally; though others have cautioned against using it this way on account of the violence of its acrimony.

LASSITUDE, *Lassitudo*, in physic, a morbid sensation that comes on spontaneously without any previous motion, exercise, or labour. This is a frequent symptom in acute distempers. It arises either from an increase of bulk, a diminution of proper evacuation, or too great a consumption of the fluid necessary to maintain the spring of the solids, or form a vitiated secretion of that juice.

The remedy in the first case is evacuation, and in the other a proper diet, or such alterative medicines as influence such a secretion.

LAST, in general, signifies the burden or load of a ship.

It signifies also a certain measure of fish, corn, wool, leather, &c. A last of cod-fish, white herrings, meal, and ashes for sope, is twelve barrels; of corn or rape-seed, ten quarters; of gun-powder, twenty-four barrels; of red-herrings, twenty cades; of hides, twelve dozen; of leather, twenty dickers of pitch and tar, fourteen barrels; of wool, twelve sacks; of stock-fish, one thousand; and of flax or feathers, one thousand and seven hundred pounds weight.

LAST, in the marshes of Kent, is applied to a court held by the twenty-four jurors, in which orders are given for the imposing and levying of taxes for preserving the said marshes.

LAST-HEIR, in law, he to whom lands come by escheat, for want of lawful heirs; who, in many cases, is the lord of whom they are held, but in others the king.

LATERAL EQUATION, in algebra, a simple equation, whose root is only in one dimension.

LATERAN COUNCILS, those councils held in the Basilica of the Latin church at Rome. See the article COUNCIL.

There have been five councils held in this place, viz. in the years 1123, 1139, 1179, 1215, and 1513.

A LATERE, a term used to denote the qualifications of cardinals whom the pope sends as legates into foreign courts, who are called legates a latere, as being assistants to his holiness, and counsellors in ordinary; these are the most considerable of the three other legates, being such as the pope commissions to take his place in councils, and so called in regard that he never gives this office to any but his favourites and confidants, who are always *a latere*, at his side.

De LATERE, legates who are not cardinals, but yet are entrusted with an apostolical legation.

LATH, in building, a long, thin, and narrow slip of wood, nailed to the rafters of a roof or ceiling, in order to sustain the covering.

These are distinguished into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, sap laths, and deal laths; of which the two last are used for ceilings and partitions, and the first for tiling only.

Laths are also distinguished according to their length, into five feet, four feet, and three feet laths, though the statute allows but of two lengths, those of five, and those of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickness, but they are commonly less.

LATH-BRICKS, bricks much longer than ordinary, used instead of laths, for drying malt; for which purpose they are extremely proper, as not being liable to catch fire, and retaining the heat much longer than those of wood; so that a very small

small fire will serve, after they are once heated. See BRICK and MALT.

**LATHE**, an engine used in turning wood, ivory, and other materials. See plate LXIV. *fig. 3.* It is composed of two legs or styles, *aa*, which are commonly about two feet ten inches high, on the upper part of which are fastened two pieces of wood called cheeks, *b, b*, parallel to the horizon; between these are two pieces of wood, called puppets, *c, c*, made to slide between the cheeks, and to be fixed down at any point at pleasure; near the upper end of one of these puppets is fastened a strong spike of tempered steel, *d*, and opposite to it, in the other, is an iron screw, *f*; by these the piece to be turned is sustained, and is turned round by means of the string *m*, put round it, and fastened above to the pliable pole *l*, and underneath to the treddle or board, *i*, moved with the foot; there is also a piece of wood between the cheeks, called a rest, *e*, whose office is to rest the tool upon, that it may lie in a steady position while the workman uses it.

When turners perform heavy work, which the pole and treddle will not command, they use instead of these a wheel (*fig. 4.*) which is turned about, sometimes with one and sometimes with two handles, according to the weight of the work; its string hath both its ends neatly fastened together, and this being fixed in a groove round the edge of the wheel, and after being crossed, put round a groove in the work, it is easily turned round with a swift and regular motion. This is the most expeditious method of working; for the springing up of the pole makes an intermission in the turning of the work, but with the wheel, it always turns the same way, so that the tool need never be taken off, unless it be to examine the work as it is doing.

Braziers, who turn pots, kettles, &c. have their lathe made in a different manner from that used by turners, as may be seen in *fig. 5.*

The puppets and rests are much stronger than those used by the turners: their edge-tools, which they call hooks, are also of a different shape from the chisels and other tools used by turners, as may be seen *ibid.* marked B 1, B 2, B 3, being bent backwards and forwards at the cutting end. And as the common turners work with a round string made of gut, the braziers work with a flat leather thong, which wrapping close and tight about the rowler of their mandril, commands it with the greater ease, and turns it more forcibly about.

Small work in metal is turned in an iron lathe, called a turn-bench, represented in *fig. 6.* When this is used, it is fixed in the chaps of a vice, and the work being fitted on a small iron axis, with a drill-barrel fitted upon a square shank near the end of it, the workman turns it round with a drill-bow, which he holds in his left hand, while he forms the moulding with a graver or other tool, which he holds in his right.

In turning oval or rose-work, the common turner's lathe must be provided with the additional parts represented in *fig. 7.* which exhibits the whole machine with all its parts ready for working, A being the fore-puppet, with its apparatus; B, the hinder puppet; C, a hollow axis, turned into a screw-fashion to direct the weight D, by means of the nut E; and F, the support of the tools, which may be raised or lowered at pleasure.

**LATHE**, or **LETH**, as used in Kent and Sussex, is part of a county, containing three or four hundreds.

**LATHRÆA**, great tooth-wort, in botany, a genus of plants, the corolla whereof consists of a single petal; the tube is longer than the cup; the limb is ringent and ventricose; the upper lip is concave, galeated, and broad, with a narrow crooked apex; the inferior one is less, and is reflex, obtuse, and trifid; the fruit is a roundish elastic capsule, consisting of two valves, and containing only one cell; it is covered with a very large patent cup; the seeds are few and roundish.

**LATHYRUS**, chickling-pea, in botany, a genus of plants, the corolla of which is papilionaceous; the fruit is a very long, cylindric, or compressed, acuminate pod, consisting of two valves; the seeds are numerous, of a cylindric, globose, or somewhat angular figure.

**LATIFOLIOUS TREES and PLANTS**, such as have broad leaves.

**LATIN**, a dead language, first spoken in Latin, and afterwards at Rome; and still used in the Romish church, and among many of the learned.

This language is principally derived from the Greek, and particularly from the Eolic dialect of that tongue, though it has a great number of words which it borrowed from the languages of the Etrusci, Osce, and other ancient people of Italy; and foreign commerce and wars, in course of time, added a great many more.

The Latin is a strong nervous language, perfectly suitable to the character of the people who spoke it: we have still works of every kind, admirably well written in the Latin, though there are vast numbers lost. The Latin is more figurative than the English, more harmonious than the French, less copious than the Greek, less pompous than the Spanish, less delicate than the Italian, but closer and more nervous than any of them.

The Latin tongue was, for a while, confined almost wholly within the walls of Rome; nor would the Romans allow the common use of it to their neighbours, or to the nations they subdued: but, by degrees they in time became sensible of the necessity of its being generally understood, for the convenience of commerce; and accordingly used their endeavours, that all the nations subject to their empire, should be united by one common language, so that at length they imposed the use of it, by a particular

ticular law for that purpose. After the translation of the seat of the empire from Rome to Constantinople, the emperors of the East being always desirous of retaining the title of Roman emperors, appointed the Latin to be still used; but at length neglecting the empire of the West, they abandoned all the care of the Latin tongue, and used the Greek. Charlemagne coming to the empire of the west, revived this language; but at length it gave way, and the French took place of the Latin.

The Latin, however, was prodigiously degenerated; for the incursions of the Goths and Vandals, brought an inundation of foreign words into it. But that was not all: when it once got into the courts of justice, it was still worse handled; till at last, being introduced amongst the monks, it was debauched to that degree, that it was almost scandalous to use it.

In this condition it was found at the Reformation, where Lud, Vives, Erasmus, &c. began to open the way for its recovery; since which time, endeavours have been used to retrieve the pure Latinity of the Augustan age. See LANGUAGE.

**LATISSIMUS**, in anatomy, a large muscle of the back, so called from its great breadth.

**LATITAT**, in law, a writ whereby all men in personal actions are called originally to the King's-bench: it is so called, as the defendant is supposed to lurk, and cannot be found in the county of Middlesex to be taken by bill; but is gone to some other county, to the sheriff of which this writ is directed, commanding him to apprehend the defendant there.

**LATITUDE**, in geography, the distance of any place from the equator, measured in degrees, minutes, and seconds, upon the meridian of that place; and is either north or south, according as the place is situated either on the north or south side of the equator: Thus let  $l$  (plate LXV. fig. 1.) represent London,  $p$  the north pole,  $eq$  the equator; then will  $ples$  be the meridian of London, and the arch  $el$  the latitude of London, which being equal to  $51^{\circ} 32'$ , the latitude of London, is said to be  $51^{\circ} 32'$  north.

The latitude of a place is always equal to the elevation of the pole above the horizon: Thus  $les$ , the latitude of London, is equal to the arch  $po$ , the elevation of the pole  $p$  above the horizon  $ho$ .—For the method of finding the latitude of a place from observations of the sun or stars, see OBSERVATION.

**Complement of the LATITUDE**, in geography, is the number of degrees, minutes, and seconds, which, added to the latitude, make it equal to  $90^{\circ}$ : Thus the complement of the latitude of London is  $38^{\circ} 28'$ ; for  $38^{\circ} 28'$  added to  $51^{\circ} 32'$  is equal to  $90^{\circ}$ .

The complement of the latitude is always equal to the elevation of the equator above the horizon,

or the angle intercepted between the plane of the equator and the plane of the horizon. Thus let  $l$  (plate LXV. fig. 1.) be London, the latitude of London is the arch  $el$ ; the complement of the latitude is the arch  $eb$ , which measures the elevation of the equator  $eq$ , above the horizon  $ho$ , or the angle  $eib$ , intercepted between the planes of the equator and horizon.

**Circles of LATITUDE**, in astronomy, are secondaries to the ecliptic, or circles drawn on the sphere of the heaven, perpendicular to the ecliptic, and intersecting each other in the poles of the ecliptic.

**LATITUDE of a Star or Planet**, in astronomy, is its distance from the ecliptic in degrees, minutes, and seconds, measured on a circle of latitude drawn through that star or planet, and may be either north or south, as the object is situated either on the north or south side of the ecliptic.

The ecliptic is drawn on the common celestial globes, by which we may see what constellations it passes through; there are also usually six circles of latitude, which by their mutual intersections shew the poles of the ecliptic, as well as divide it into twelve equal parts, answering to the numbers of months in a year. Plate LXV. fig. 2. represents a celestial globe, where  $AG$  is the ecliptic,  $N$  the north,  $S$  the south pole of the ecliptic,  $NAS$ ,  $NBS$ ,  $NCS$ ,  $NDS$ , &c. are circles of latitude, or rather halves of them, which is as much as can be seen at one view upon the convex of the solid globe. The star  $H$  is in so many degrees, minutes, and seconds of north latitude as the arch  $HA$  amounts to; the star  $I$  is in south latitude, the quantity whereof is measured by the arch  $IB$ .

From what has been said, it appears that we must carefully distinguish the different notions of latitude, when applied to stars in the heaven, or places on the earth; that is, between latitude in astronomy, and latitude in geography; for in the heaven, or upon the celestial globe, it is the distance from the ecliptic; but upon the earth, or upon the terrestrial globe, it is the distance from the equator. Indeed, sometimes we consider the distance of the heavenly bodies from the celestial equator; but this is called declination: See DECLINATION.

The latitude of a planet is either heliocentric, or geocentric.

**Heliocentric LATITUDE of a Planet** is the latitude it would appear in to a spectator placed in the sun.

**Geocentric LATITUDE of a Planet**, is the latitude it appears in to an inhabitant of the earth. See GEOCENTRIC Latitude.

To illustrate the difference between the heliocentric and geocentric latitude of a planet, let  $AB$  (plate LXV. fig. 3.) be the orbit of the earth,  $CD$  the orbit of Mars, both viewed with the eye in their common section continued, whereby they appear straight lines; let  $E$  and  $F$  be opposite points of the ecliptic;

Fig. 1. Latitude.

Fig. 2. Latitude.

Fig. 3. Latitude.

Fig. 4. Latitudo Transversum.

See Way.

Fig. 5.

See Way.

Fig. 6.

Fig. 7.

Fig. 9.

ecliptic: suppose Mars to be in his south limit at C; if he were at that time viewed from S, the center of the sun, he would appear in the sphere of the heaven at the point H; his heliocentric latitude then is F H. But let Mars in C be viewed from the earth, and he will appear in different places, according as the earth is in different parts of her orbit; for if the earth be at B, a line drawn from B through C shews the apparent place of Mars to be at g, and his geocentric latitude is then F g; if the earth be at A, the apparent place of Mars will be in G, and his geocentric latitude F G; if the earth be in any other part of her orbit, as at the point I or K, it is easy to see, by a line drawn from either of those points through Mars at C, that he will appear in different places in the sphere of the heaven, and would be in different geocentric latitudes.

*North ascending LATITUDE of the Moon*, when she proceeds from the ascending node towards her northern limit or greatest elongation.

*North descending LATITUDE*, is when the moon returns from her northern limit to the descending node.

*South descending LATITUDE*, when she proceeds from the descending node to her southern limit.

*South ascending LATITUDE*, when she returns from her southern limit to her ascending node.

And the same things hold good of the other planets.

**LATITUDINARIAN**, a person of moderation, with regard to religious opinions; who believes there is a latitude in the road to heaven, which may admit people of different persuasions.

**LATTEN**, a name formerly given to the plates of iron covered with tin, and now usually called tin, of which our mugs, tea-cannisters, and the like are made.

**LATTEN-BRASS**, plates of milled brass, reduced to different thickness, according to the uses it is intended for.

**LATUS Rectum**, in conics, the same with parameter. See **PARAMETER**.

**LATUS TRANSVERSUM of the Hyperbola**, a right line intercepted between the vertices of the two opposite sections; or that part of the common axis, which is between the vertices of the upper and lower cones.

Such is the line E D (plate LXV. fig. 4.) where also D d and E e may be the parameters, or latus rectums belonging to the two opposite sections D L R O and O E O R.

To this latus transversum answers the longest diameter in the ellipsis, which Apollonius calls the transverse axis or diameter.

**LATUS PRIMARIUM**, a right line belonging to a conic section, drawn through the vertex of the section of the cone, and within it, as the line E E or D D, fig. 4.

**LAVANDULA**, lavender, in botany, a shrubby plant, with its leaves set in pairs, the stalks square when young, and round when grown woody; producing, on the tops of the branches, naked spikes of blue labiated flowers, of which the upper lip is erect and cloven, the lower divided into three roundish segments.

**LAVANDULA Minor five spica**, lavender with oblong, very narrow, somewhat hoary, undivided leaves; a native of dry gravelly soils in the southern parts of Europe, common in our gardens, and flowering in July.

The flowers of lavender have a fragrant smell, to most people agreeable, and a bitterish, warm, somewhat pungent taste: the leaves are weaker, and less grateful. They are often employed as a perfume; and medicinally, as mild stimulants and corroborants, in vertiges, palsies, tremors, and other debilities of the nervous system, both internally and externally.

The flowers are sometimes taken in the form of conserve; into which they are reduced, by beating them, while fresh, with thrice their weight of double refined sugar. Their fragrance is less injured by beating or bruising them, than most of the other odoriferous flowers, but is nevertheless considerably diminished: the flavour of the leaves is of a much less destructible kind.

Water extracts by infusion nearly all the virtue, both of the leaves and flowers. In distillation with water, the leaves yield a very small portion of essential oil; the flowers a much larger, amounting, in their most perfect state, when they are ready to fall off spontaneously, and the seeds begin to shew themselves, to about one ounce from sixty. The oil is of a bright yellowish colour, a very pungent taste, and possesses, if carefully distilled, the fragrance of the lavender in perfection. It is given internally from one drop to five, and employed in external applications, for stimulating paralytic limbs, and for destroying cutaneous insects. The decoction, remaining after the distillation of the oil, is disagreeably bitterish, and somewhat saline.

Rectified spirit extracts the virtue of lavender more completely than water. The spirit elevates also in distillation a considerable part of the odoriferous matter of the leaves, and greatest part of that of the flowers; leaving, in the inspissated extracts, a moderate pungency and bitterishness, with very little smell. A spirit prepared by pouring a gallon of proof spirit on a pound and a half of the fresh gathered flowers, and drawing off five pints by the heat of a water bath, is richly impregnated with the fragrance of the flowers. More compound spirits of this kind, in which other aromatics are joined to the lavender, have been distinguished by the name of English or palsy drops. The college of London directs three pints of the simple spirit of lavender, and one pint of the spirit of rosemary, to

be digested on half an ounce of cinnamon, half an ounce of nutmegs, and three drams of red saunders, as a colouring ingredient: the college of Edinburgh orders a gallon and a half of rectified spirit of wine to be drawn over from three pounds of fresh lavender flowers, one pound of those of rosemary, and three ounces of lemon-peel; and afterwards three ounces of cinnamon, one of cloves, one of cubebs, and two of red saunders, to be macerated for three days in the distilled spirit. These preparations are taken internally, on sugar, or in any convenient vehicle, from ten to an hundred drops, and used externally in embrocations, &c.

**LAVENDULA** *Major five vulgaris*, broad lavender, with longer, wider, and hoarier leaves, and much larger spikes, though smaller flowers; common in the southern parts of Europe, but rare among us. The name spike is applied by foreign writers to this species, by some of ours to the first.

The broad-leaved lavender is stronger both in smell and taste than the narrow, and yields in distillation almost thrice as much essential oil; but the flavour both of the oil and of the plant itself, is much less grateful: the oil is likewise of a much darker colour, inclining to green. Watery and spirituous extracts, made from the two sorts of lavender, are very nearly alike; the difference seeming to reside only in the volatile parts.

**LAVATERA**, in botany, a genus of plants, whose flower-cup consists of a double perianthium; the corolla composed of five plane heart-shaped petals, coalescing at their base; the filaments are numerous, joining in a column below, and topped with reniform antheræ: the fruit is a verticillated depressed arilla, jointed round a columnar receptacle: the seeds are solitary and kidney-shaped.

**LAVATORY**, or **LAVOREDO**, an appellation given to certain places in Chili and Peru, where gold is separated from the earth by means of washing.

**LAUDANUM**, a preparation of opium. See the article **OPIUM**.

**LAVENDER**, the same with lavenderula. See **LAVENDULA**.

**LAVENDER-COTTON**, in botany. See the article **SANTOLINA**.

**LAVER**, a sacred utensil in the temple of Jerusalem, consisting of a basin, whence they drew water by cocks.

**LAUNCH**, among sailors, a sort of boat used by the French, Italian, and Spanish ships; and is peculiar to those which are employed in the Mediterranean trade, being better fitted for the ports of that sea than a long-boat, than which it is generally much longer, and more flat-bottomed, and also sharper before. See **BOAT**.

**LAUNCHING** a Ship, or Boat, pushing them into the water from an ascent.

When the ships of the ancients, particularly those of Greece, were launched, they were ornamented with garlands and flowers; the mariners also adorned with crowns, who shouted with loud acclamations and other expressions of mirth and joy; and being purified by a priest, with a lighted torch, and egg and brimstone, or after some other manner, were consecrated to the god whose image they bore.

In the launching of ships now-a-days, the same or similar expressions of joy and feasting are used, colours are displayed, and sometimes music performed.

The greatest ship ever launched in England was the Britannia, of 100 guns, at Portsmouth; such very large ships being usually built in dry docks, and afterwards floated out by throwing open the flood-gates, and suffering the water to enter, when they are finished.

**LAUNDER**, among miners, a place where they wash the powdered ore.

**LAUNIARD**, a rope passing alternately through two dead-eyes, to draw them together. See the article **DEAD-EYE**.

In every dead-eye there are three holes, and two of these dead-eyes being fastened in two ropes, opposite to each other, and the launiard passing alternately through the first hole in the upper, then the first hole in the lower, then the second hole in the upper, proceeds till the whole purchase is completed: after which, the launiard, being well greased, is drawn extremely tight through all its parts, and draws the rope tight to which the dead-eyes are fastened: thus the shrouds of the masts are drawn tight by fixing a dead-eye in the lower end of each, with another directly underneath it, which is bolted to the ship's side by a short chain; the launiard passing through these, is drawn tight by mechanical powers, and consequently draws tight the shroud to which it is connected. See **SHROUD**.

**LAUNIARD** is also a small cord or line by which any thing is held fast, and can be occasionally loosened, as the launiard of the buoy, the launiard of a port, &c.

**LAURA**, in church history, a name given to a collection of little cells, at some distance from each other, in which the hermits, in ancient times, lived together in a wilderness.

These hermits did not live in community, but each monk provided for himself in his distinct cell. The most celebrated lauras mentioned in ecclesiastical history, were in Palestine; as the laura of St. Euthymius, at four or five leagues distance from Jerusalem; the laura of St. Saba, near the brook Cedron; the laura of the Towers, near the river Jordon, &c.

**LAUREATION**, in the universities of Scotland, signifies the act of taking the degree of master of arts, which the students are permitted to do after four years study.

**LAUREL**, in botany, a well known ever-green; it delights in shade, and is a great embellishment to the parts of a wilderness or large shrubberies; it is a tree that loves liberty, and therefore very improper for a headed plant: when planted as a hedge it is very beautiful, when properly pruned with a knife, and not with its great enemy the sheers. It is propagated from berries, cuttings, or layers. Its cover is delightful to all kind of game, as hares, pheasants, woodcocks, &c. and will thrive in any land that is not over hot. For its generical characters, see the article **PADUS**, of which it is a species.

**LAURENCE**, or *Canons regular of St. LAURENCE*, a religious congregation in France, said to have been founded by St. Benedict.

**LAURUS**, the bay-tree. See the article **BAY**.

**LAURUSTINUS**, in botany, a well known flowering shrub, much admired for its early blowing in the spring: it is propagated by laying down the young branches in autumn, when in a year's time they will be fit to be taken off and planted; the season for transplanting them is in autumn. For the generical characters of the laurustinus, see the article **VIBURNUM**, of which it is held a species.

**LAW** denotes the command of some person or power, whose precept carries along with it the reason of obedience.

The word is derived from the Saxon *lab*, which signifies the same thing.

**LAW of Arms**, is a law which gives precepts how to proclaim a war, to attack the enemy, and to punish offenders in the camp.

**LAWS of Nature or Motion**, in physics, are axioms or general rules of motion and rest, observed by all natural bodies in their actions on one another; of these Sir Isaac Newton has established the three following:

1. All bodies continue their state of rest or uniform motion in a right line, till they are made to change that state by some external force impressed upon them.

This law is no other than the universal property of bodies, called passiveness or inactivity; whereby they endeavour to continue the state they are in, whatever it be. Thus a top only ceases to run round, on account of the resistance it meets with from the air, and the friction of the plane whereon it moves. And a pendulum, when left to vibrate in vacuo, where there is nothing to stop it but the friction arising from the motion of the pin on which it is suspended, continues to move much longer than one in the open air.

2. The change of motion, produced in any body, is always proportionable to the force whereby it is effected; and in the same direction wherein that force acts.

This is an immediate consequence of this axiom, the effect is always proportionable to its cause. For instance, if a certain force produces a certain mo-

tion, a double force will produce double the motion; a triple force, triple the motion, &c. If a body is in motion, and has a new force impressed on it in the direction wherein it moves, it will receive an addition to its motion, proportional to the force impressed; but if the force acts contrary to its motion, the body will then lose a proportional part of its motion: again, if the force is impressed obliquely, it will produce a new direction in the motion of the body, more or less different from the former, in proportion to its quantity and direction.

3. Re-action is always contrary and equal to action; or the actions of two bodies upon each other are equal, and in contrary directions.

Thus, suppose a stone or other load to be drawn by a horse; the load re-acts upon the horse, as much as the horse acts upon the load; for the harness, which is stretched equally between them both ways, draws the horse towards the stone, as much as it does the stone towards the horse; and the progressive motion of the horse is as much retarded by the load, as the motion of the load is promoted by the endeavours of the horse. This will be better explained from the following instance; let a person sitting in a boat draw another boat equally heavy towards him, they will both move towards each other with equal velocities: let the boat he sits in be the lightest, and it will move the fastest; because the action being equal on both sides, the same quantity of motion will be given to each boat, that is, the lesser will have the greater velocity.

We have a farther confirmation of this from attraction. Supposing two bodies attracting one another, but prevented from coming close together by some other body placed between them; if their respective actions, by which they tend towards each other, were not equal on both sides, then would the intermediate body be pressed more one way than the other, and so all three would begin to move by themselves the same way; but that three bodies should be put in motion after this manner, when no external force acts upon them, is contrary to experience; consequently, whatever different degrees of force any two bodies may be capable of exerting, their mutual actions on each other are always equal. This may be tried with a load-stone and iron; which being put into proper vessels, contiguous to one another, and made to float on the surface of water, will be an exact counterbalance to each other, and remain at rest, whatever be the attractive power of the loadstone, or the proportion of their respective magnitudes.

These laws receive an abundant additional proof from hence, viz. that all the conclusions that are drawn from them in relation to the phenomena of bodies, how complicated soever their motions be, are always found to agree perfectly with observation. The truth of which sufficiently appears in all parts of the Newtonian philosophy.

## L A Y

**LAWN**, a large plain in a park, or adjoining to some grand seat. The most convenient situation is in the south or south-east side of a house. If the lawn be a square, three avenues may break out from three of the angles, and meet in the fourth angle opposite to the house: it may be bounded with walks or a single row of lime trees set at a good distance from one another. A circle is a good figure for a lawn, but must break off before it comes against the front. A triangle is a very proper figure, but should be obtuse or right angled next the front.

Many persons have preferred the lime-tree for this purpose, on account of their regular growth: but as the leaves of this tree often change their colour, and begin to fall very soon in the autumn, occasioning a great litter in the garden; and from the end of July the trees make but an indifferent appearance; so they are not to be esteemed for these plantations.

The elm, oak, beech, and chestnut, among the deciduous trees, are to be preferred to all others, as they keep their leaves late in autumn: and these are all of them large-growing trees; so are very proper for this purpose.

**LAXATIVE MEDICINES**, are such as regard either the belly or entire habit, and produce this effect by some softening quality that takes away the tenacity of the fibres, and facilitates the passage of the contents in the internal tube.

**LAY Brothers**, among the Romanists, those pious, but illiterate persons, who devote themselves, in some convent, to the service of the religious.

**LAY Land**, or **LEY Land**, in husbandry, fallow-ground, or such as lies untilled. See **LEYS**.

**LAY Man**, one who follows a secular employment, or has not entered into holy orders.

**LAY Man**, among painters, a small statue, either of wax or wood, whose joints are so formed, that it may be put into any attitude or posture. Its principal use is for adjusting the drapery in cloathing of figures.

**LAYERS**, in gardening, are tender twigs or shoots of trees, part of which are laid or buried in the ground, till having struck root, they are afterward separated from the parent tree, and become distinct plants. Many plants and trees are propagated by laying, when all other methods fail; and particularly those exotic trees which do not produce seeds with us. The operation is performed by slitting the branches from the middle of a joint upwards a little way (as is practised with carnations) and laying them about half a foot in the ground; and if they are not pliable, they should be pegged down with a hook; with some plants a twist at the place intended to strike root will suffice, or by tying a piece of wire round the part, and making punctures with an awl just above the place of bandage.

## L A Z

If the branches intended to be layed are not within reach of the ground, then it will be necessary to make use of tubs or pots filled with proper mould, and placed on trussels, posts, or some such conveniencies, to receive the branches. The season for laying down deciduous hardy trees is in October, but for such as are tender, in March, and for evergreens, June or August are good seasons. Though layers may be laid down at any time, the before-mentioned seasons are most proper for the reasons following; because they have the whole winter and summer to prepare and draw root; for at these times of the year the sun has sufficient power on the sap of the tree to feed the leaf and bud, but has not power sufficient to make a shoot; and if that small quantity of sap that arises be hindered, as it will by some of the preceding ways of laying, the leaves and buds will gently crave of the layer, and by that means will prepare the layer to take root or put forth roots a little to maintain itself, finding it cannot have a proper supply from the mother plant. The harder the wood of a tree is, the young shoots will take root the best; but if the wood is soft, the older branches will more readily root, and consequently sooner make a tree.

**LAZARETTO**, or **LAZAR HOUSE**, a public hospital for the reception of the sick poor; and in some countries it is a detached edifice for persons coming from places suspected of the plague to perform quarantine in.

**LAZARUS**, or **LAZARO**, a military order instituted at Jerusalem by the Christians of the West, when masters of the Holy Land, who received pilgrims under their care, and guarded them on the roads from the insults of the Mahometans.

This order was instituted in the year 1119, and confirmed by a bull of pope Alexander IV. in 1255, who gave it the rule of St. Augustine.

**LAZULA**, or **LAPIS LAZULI**, a sort of stone, from whence the celebrated colour called ultramarine is made.

This is one of the ores of copper, the basis of which is a debased crystalline matter, coloured with an elegant and beautiful blue. It is a very hard compact stone, inasmuch as to come into the rank of those that take a high polish, and are not liable to be scratched by accidents; and therefore is worked in a number of different toys. It is found in detached lumps usually of the size of a man's fist, often smaller, and sometimes of four or five pounds weight: it is never covered with any coat or crust, but resembles those stones which have been washed off from whole strata, and smoothed or rounded by accidents afterwards. It is of a naturally smooth and glossy surface; and its general colour is the colour already mentioned; but this is variegated in a very beautiful manner with spots or clouds of white, and with veins of a fine shining gold.

gold colour. It has these variegations, in different degrees, in several masses, and in general most to be valued, as it has least of them; for though very beautiful to the eye, they are foreign to all the uses they are put to, except when it is cut as a gem. The white clouds or veins, for this matter is sometimes, though more rarely disposed of in the last form, are usually of a dead and opaque hue; but sometimes they are bright and pellucid as crystal; this last state of them adds greatly to the beauty of the stone: the yellow ones are always bright and glossy; they have been supposed by many to be veins of gold, and the stone has been thence called a gold ore; but they are in reality only marcasite. Sometimes that gold-like matter is not disposed in veins, but in spots and stars, and in this case the stone is the sapphire of the ancients; for they knew the gem we call the sapphire by a very different name, calling it the sky-blue beryl; and describing what they meant by the word sapphire to be a stone, opaque, of a fine blue, and variegated with spots of a gold colour in form of stars. All the variations of this stone are subject, besides, to other accidental foulnesses, and are sometimes debased to the state of a mere common blue copper-colour.

**LEAD**, *Saturn*, in natural history, a pale or livid white metal, soon losing its brightness in the air, and contracting a blackish or greyish ash-colour; very soft and flexible; unelastic, and unsonorous; the heaviest of all metallic bodies but gold, quicksilver, and platina: it is upwards of eleven times heavier than an equal bulk of water.

It melts in a very small degree of fire, long before it grows red-hot: in a strong red heat it emits visible fumes. It loses of its malleability in proportion as it is heated: by nimble agitation, when it is just ready to melt, or when returning from a fluid to a consistent state, it may be divided into small grains, or powder. Granulated lead is commonly prepared, by pouring the melted metal into a wooden box rubbed on the inside with chalk, and strongly shaking it till it sets or becomes solid; when large quantities are prepared, a wooden trough is made use of. It is formed into round granules or shot, by pouring the melted lead into cold water, through a perforated plate; a little orpiment being added to the metal infusion; this improves its hardness, and makes it run more regularly into globules without drawing a tail.

Lead, when just become fluid, looks bright like quicksilver but presently contracts on the surface a variously coloured powdery pellicle. Some have supposed that this was an heterogenous substance; and that the lead by its separation, became purer. But after this imaginary purification, it will still, upon continuing the fire, exhibit a pellicle as at first: if this be taken off, or the metal stirred, so as to expose a fresh surface to the air, a new one will arise, till by degrees the whole quantity is changed into a

dusky powder or calx, called *plumbumustum*. The injection of a little fat, charcoal powder, or other inflammable matters, prevents this change, and readily revives the calx into lead again, notwithstanding Boerhaave's assertion that the calx of lead is very hard to reduce.

Calx of lead, exposed to the fire in a furnace so contrived as that the flame may play upon its surface, becomes white, yellow, and at length of a bright red colour; hence the yellow lead or masticot, and the red lead or minium of the painters. See the articles *MASTICOT* and *MINIUM*.

If lead be urged with a bright red heat, it changes by degrees into a yellow, flashy scoria, called litharge, of a paler or deeper colour, according to the degree of fire it has undergone. See *LITHARGE*.

All the calces and scorias of lead vitrify more easily than those of any other metal: exposed to a moderately strong fire, they quickly run into a transparent yellow glass. This glass, in fusion, powerfully dissolves and vitrifies the more refractory metallic calces and earths; and unless saturated with these kinds of additions, corrodes and sinks through the common crucible.

If gold or silver be mixt with lead, and exposed to the fire, the lead scorifies, as it would by itself, and arises to the surface, so as to be raked off in the form of glass or litharge; at the same time carrying with it any imperfect metal that the gold or silver had been mixed with, but leaving those perfect metals themselves unhurt. Hence gold and silver are purified by means of lead from admixtures of the baser metals; and hence lead is called by the chemists, *balneum solis & lunæ, lavacrum regis & reginæ, sapa metallorum*, &c. The litharge met with in the shops is produced in those works where gold and silver are thus purified; and contains the heterogenous metals which the gold or silver had been mixt with.

Lead exposed for sometime to the steam of vinegar or other vegetable acids, is gradually corroded into a white calx, which is the ceruss or white lead of the shops. See *CERUSS*.

Lead is employed for various mechanic uses; as in thin sheets for covering buildings, for pipes, pumps, cisterns, statues, shot, bullets, windows, for securing iron bars in hard stones, for sundry kinds of large vessels for evaporation, and many other mechanic purposes. It has been observed that plants do not thrive so well in leaden as in earthen and wooded vessels. Its principal use in the chemical arts are for promoting the vitrification of earthy and stony matters, in the making of glass, or in the smelting of ores, or in the glazing of earthen vessels; for the refining of gold and silver; for the eliquation of silver from copper; for forming with oil the basis of varnishes and paints.

The effects of lead on the human body are dangerous.

gerous: those who are exposed to its vapours in the fire, and even those who grind its calces, minium, cerufs, and litharge, for the painters, are subject to violent gripes and constipations of the bowels, contractions of the limbs, and other disorders. Much more hurtful is the internal use of lead corroded or dissolved by acids, as cerufs, saccharum saturni, the solution in vinegar called acetum lithargyrii, or the tincture drawn from the saccharum with spirit of wine, commonly called tinctura antipthifica. The saturnine preparations are applied externally with safety, as coolers, repellents, and deficatives: its calces, dissolved in oils, form the basis of most of the official plasters.

Culinary vessels, lined with a mixture of tin and lead, which is the usual tinning, are apt to communicate to acid foods pernicious qualities, and require to be used with great precaution. In Holland, and perhaps in other places, it has been customary to correct the more offensive expressed oils, as that of rape-seed, so as to substitute them to oil of olive or oil of almonds, by impregnating them with lead: this dangerous abuse may be discovered by mixing a little of the suspected oil with a solution of orpiment made in lime water; on shaking them together, and suffering them to stand some time, the oil, if it has any saturnine taint will appear of an orange-red colour; if pure, of a pale yellowish. The same abuse has been extended also to acid wines, which dissolve so much lead as to acquire a sweet taste, and to become slow poisons. The lead is readily discovered in these likewise, by the same sulphureous solution, which changes the colour of wines impregnated with this metal to a brownish red or blackish; lead, whether dissolved, or in its metallic form, being constantly stained by sulphureous liquors or vapours.

Lead is sometimes found in the earth native, or in its metallic form, though very rarely pure. Its common ores are nearly of the colour of lead itself, and appear composed of cubes or parallelopeds, sometimes large and regular, sometimes irregular and small. There are lead ores also of a white, greyish, or greenish colour, and prismatic figure; but these are rarely met with. The ores of silver, copper, and other metals, except tin and iron, have often a lead ore intermixed. The lead is extracted by fusion in contact with the fuel; the furnace being sufficiently heated with wood or charcoal, the powdered ore is thrown in by degrees, and fresh fuel and ore occasionally supplied: the lead, revived by the inflammable matter of the coals, runs down into a basin at the bottom of the furnace; from whence it is laded out and cast into iron moulds, into large masses, called pigs of lead. All the common lead ores contain some silver; the steelgrained, and such as are composed of small cubes, have generally more silver than the compact and large diced sorts: the white

and green scarcely hold any. The silver is extracted, when its quantity is considerable enough to bear the expence of extracting it, by scorifying the lead upon a test; the whole being kept in fusion on a hearth made of bone-ash, or other like materials, the lead partly vitrifies and sinks into the hearth, and partly turns to litharge, which floats on the surface, and is raked or blown by bellows to one side; the silver at length remaining by itself. Lead almost always contains some portion of copper; and hence the silver obtained in this operation is scarcely ever free from some admixture of that metal.

**LEADWORT**, in botany. See the article **PLUMBAGO**.

**LEAF**, *Folium*, a very essential and ornamental part of plants, whose chief office is to subtilise and give more spirit to the abundance of nourishing sap, and to convey it to the buds of the future shoots, which are always formed either at the base of the leaf, or its footstalk.

Leaves are properly the most extreme part of a branch, extending into some determinate length, breadth, and figure, and are furnished with veins and nerves.

Botanists consider the leaves with regard to their structure, surface, shape, consistence, edges, situation, and size: with regard to their structure, they are either single, as those of the apple, pear, and plumb tree, or compound, as those of the strawberry, parsley, &c. a single leaf is one which is either immediately joined to the branch or connected with it by a footstalk; a leaf is said to be compound, when there are more than one upon a petiole or footstalk: with respect to their surface, they are either flat, as the origany, or in bunches, as the houseleek: with regard to their shape, they are either lanceolated, cordated, acuminate, hastated, &c. (see **LANCEOLATED**, &c.) and are either thin and fine, as those of the hypericum; or thick and gross, as those of purslane; or fleshy, as those of several kinds of aloes; or woolly; as those of marsh-mallows: with regard to their edges, leaves are cut slightly, as in some species of geums, or deep, as in some of the centaury: with respect to their situation, they are either ranged alternately, as the alaternus; or opposite to each other, as the phillyrea, mint, baum, &c. with regard to their size, they are either very large, as those of the musa; or moderate, as those of the fig and vine; or small, as those of the elm or apple-tree; or very small, as those of the heath, phyllica, &c.

Many sorts of plants, whose roots issue forth from the small end of the seed, put out two small leaves that are very unlike those which the plant afterwards produceth; for as soon as the root has taken hold of the ground, between these false leaves (commonly called the seed-leaves) there comes forth a shoot which produces leaves like those of the mother plant;

plant: of this manner of growth there is an infinite number of plants.

Naturalists generally ascribe a four-fold use to leaves.

1. Chiefly that they do, in the spring time, receive the crude humours into themselves, divide them very minutely, and move them strongly in the utricles, and, perhaps, draw in from the air, what is necessary, though unknown to us, and carry back great plenty of elaborated juice to the plant.

2. That there may be a transpiration of what is unprofitable, answering to the discharge made by sweat; for sometimes these excretory vessels of the leaves, are so overcharged by the great plenty of distending humour, or juice, that they burst in the middle, and let go the more subtile parts; nor is it seldom that, in a hot season, great plenty of juices are this way discharged and imbibed: thus, manna is found to exude, or sweat forth, from the leaves of certain trees, if a cold night should follow a hot day; and the same thing frequently happens in divers other plants and trees, as we learn from bees flying to the lime-tree that they may gather that gummous substance from the leaves, and it is from the surface of the leaves, as well as from the flowers, those animals collect their honey; but if the heat should be less, all the superfluous humours, except those which, perhaps, are transmitted by insensible transpiration through the arterial vessels, exhaling naturally, are seen to return into the trunk.

3. That the bibulous vessels dried by the diurnal heat (and for this reason may be compared to veins) may imbibe in the night time, especially those watery parts which, among others, lie hid in the air, under the form of a very thin dew, and therefore supply the loss, made by the arteries, by the new moisture received.

4. Lastly, The leaf serves chiefly for this purpose, that it may keep, or nourish, the eye, or germ, till the germ, by degrees, growing out to a greater bulk, presses together the vessels of the footstalk, whence the humour is, by little and little, stopped in the leaf, till it cannot any more return to the footstalk, which, by the ceasing of the afflux and reflux of the nutritious juice, grows putrid; whence, a consumption being caused, the leaf dies and falls off, which is the chief cause of the falling of the leaves in autumn.

Some have made observation, that all evergreens have their wood close and compact between their annular circles, and that their holding their leaves all the winter, proceeds from the nature of their sap, which is of a clammy and turpentine nature; and that this sap is easily condensed by cold, and requires a considerable share of heat to make it thin and put it in motion: thus, a little cold condenses pitch or turpentine, but it must be a frost that stays the motion of the water; whence it happens, that

those trees which hold their leaves, will grow much better under the droppings of other great trees, than such as shed their leaves; because their turpentine sap shoots off the drops, and prevents their entering the vessels in too great quantities.

Dr. Hales says (in his Treatise on Vegetation) it is plain, from many experiments and observations which he mentions, that leaves are very serviceable in the work of vegetation, by being instrumental in bringing nourishment from the lower parts within the reach of the attraction of the growing fruit, which, like young animals, is furnished with proper instruments to suck it thence. But the leaves seem also designed for many other important services, for nature admirably adapts her instruments so as to be, at the same time, serviceable to many good purposes. Thus the leaves, in which are many excretory ducts, separate and carry off the redundant watery fluid, which, by being long detained, would turn rancid and prejudicial to the plant, leaving the more nutritive parts to coalesce, part of which nourishment, we have good reason to think, is conveyed into vegetables through the leaves, that plentifully imbibe the dew, which contains salt, sulphur, &c. for the air is full of acid and sulphureous particles, which, when they abound much, do, by the action and re-action between them and the elastic air, cause that sultry heat which usually is attended with lightning and thunder; and these new combinations of air, sulphur, and nitrous spirit, which are constantly forming in the air, are doubtless very serviceable in promoting vegetation, when, being imbibed by the leaves, they may not improbable be the materials out of which the more subtile and refined principles of vegetables are formed; for so fine a fluid as the air, seems to be a more proper medium wherein to prepare and combine the more exalted principles of vegetation, than the grosser watery fluid of the sap.

That there is plenty of these sulphureous particles conveyed in the leaves, is evident, from the exudations that are found on their edges, of which the bees are observed to make their waxen cells, as well as from the dust of the flowers; and that it abounds with sulphur, is plain, from its burning freely; whence it appears, that the great use of leaves is to perform, in some measure, the same office, for the support of vegetable life, as the lungs of animals do for the support of animal life; plants, very probably, drawing through their leaves some part of their nourishment from the air.

LEAF, in architecture, the representation of the leaf of the acanthus on the capital of the Corinthian and Composite orders. See the articles CORINTHIAN and COMPOSITE.

LEAF, in clocks and watches, an appellation given to the notches of their pinions. See the articles CLOCK and WATCH.

LEAGUE, a measure of length, containing more

or less geometrical paces, according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, being a land measure mostly peculiar to the French and Germans, contains three thousand geometrical paces, or three English miles.

The French league sometimes contains the same measure, and in some parts of France it consists of three thousand five hundred paces: the mean or common league consists of two thousand four hundred paces: the little league of two thousand. The Spanish leagues are larger than the French; seventeen Spanish leagues making a degree, or twenty French leagues, or sixty nine and an half English statute miles. The Dutch and German leagues contain each four geographical miles. The Persian leagues are pretty near of the same extent with the Spanish; that is, they are equal to four Italian miles; which is pretty near to what Herodotus calls the length of the Persian parasang, which contained thirty stadia, eight whereof according to Strabo, make a mile.

LEAGUE also denotes an alliance or confederacy between princes and states for their mutual aid, either in attacking some common enemy, or in defending themselves.

LEAK, among sailors, a cranny or hole through which water enters into a ship either through her deck or sides.

LEAKAGE, the state of a vessel that leaks, or lets water, or other liquid, ouze in or out.

Leakage, in commerce, is an allowance of 12 per cent. in the customs allowed to importers of wines for the waste and damage it is supposed to have received in the passage: an allowance of two barrels in twenty-two is also made to the brewers of ale and beer, by the excise office.

LEAP, *Salto*, in music, is when the song does not proceed by conjoint degrees, as when between each note, there is an interval of a third, fourth, fifth, &c. See DEGREE and CONJOINT.

LEAP YEAR, the same with bissextile. See BISSEXTILE.

LEASE, in law, a demise or letting of lands; tenements or hereditaments unto another for life, term of years, or at will, for a rent reserved.

LEASE and RELEASE, as used in our law, signifies a certain instrument, in writing, for the conveyance of a right or interest in lands and tenements in fee to another

LEASH, among sportsmen, denotes three creatures of any kind; but chiefly greyhounds, foxes, bucks, and hares.

The term leash also signifies a line to hold in a hunting dog; and a small long thong of leather, by which a falconer holds his hawk.

LEATHER, the skin of several kinds of beasts, dressed and prepared for the use of the various ma-

nufactures, whose business is to make them up. The butcher and others who flay off their hides or skin, dispose of them raw or salted to the tanner and tawer, and then to the shamoy, Morocco, and other kind of leather dressers, who prepare them according to their respective arts, in order to dispose of them among the curriers, glovers, harness-maker, coach-makers, saddlers, breeches-makers, gilt leather-makers, chair-makers, shoe-makers, bookbinders, and all in any way concerned in the article of leather.

The three principle assortments of leather are tanned or tawed, and oil and alum-leather; and it may be affirmed, with great truth, that the skins of our own production, and those imported from our colonies, when dressed in this kingdom, make the best leather in the world, and that therefore this is an article of great importance to the trade of the nation.

Though there is no little difference between the dressing of shamoy-leather, alum-leather, Hungary leather, Morocco leather, parchment, and tanning; yet the skins which pass through the hands of these several workmen, ought to have been for the most part, at least washed clean from blood and impurities in a running water; set to drain, worked with the hands, or pounded with wooden pestles in a vat; put into the pit, which is a hole lined either with wood, or with stone and mortar, filled with water in which quick-lime is dissolved, in order to loosen the hair that it may be easily rubbed off without injuring the skin; drawn out, and set to drain on the edge of the pit; stretched on the leg or horse, in order to have the hair scraped off with a blunt iron-knife, or wooden cylinder; the membranes on the fleshy side, and the scabs or roughness on the grain-side, pared off with a sharp-knife, and the skins rubbed with a whetstone, to take off any particles of the lime, or any thing else that may occasion hardness; thickened by different sorts of powder, whereby they become greater in bulk, and so much lighter as gradually to rise to the surface of the water; stretched out green or half dried, and piled one over another; or put up separate after they are dried, and hung out to air upon poles, lines, or any other way: which must be repeatedly done in the dressing of small skins. This alternate transition from the liquid of the air into that of water, and from water in the air, with the assistance of lime, salts, and oils, opens the inmost fibres of the skin so effectually, as greatly to facilitate the introduction of substances proper for making them pliant, without rendering them thinner.

The alum leather dresser dresses all sorts of white leather from the ox-hide to the lamb skin; for dressing the sadler's leather, he uses bran, sea-salt, and alum; and for that which the Glover uses, after the common preparatives, he first employs bran, and

then with salt, alum, fine flower, and yolks of eggs mixed in hot water, he makes a sort of pap, with which the skins are smeared in a trough.

The shamoy leather-dresser soaks in oil, not only the skins of the true shamoy (which is a wild goat) but likewise those of all other goats. The tanner uses the bark of young oaks ground in a tanning-mill, in which he soaks the skins more or less, according to the different services expected from them, their chief use being to remain firm and keep out water. In certain cases, instead of tan, he uses redon, which is chiefly used for tanning ram, sheepskins, and dressing Russia leather. But for the different methods in which the tanner, currier, Russia and Morocco leather-dressers, proceed, in finishing their skins, see the articles CURRYING, TANNING, &c.

LEAVEN, a piece of sour dough, used to ferment and render light a much larger quantity of dough or paste.

LECHEA, in botany, a genus of plants whose flower consists of a triphyllous cup, with three oblong petals and three stamina: the fruit is an ovate, triquetrous, trilocular capsule, containing three egg-shaped seeds, angulated on their backs.

LECTICA, in Roman antiquity, a vehicle in which people were carried in a reclining posture.

LECTISTERNIUM, a religious fast or banquet of the ancient Romans. In times of public danger or calamity, or of thanksgiving for some happy event, the republic ordered solemn feasts to be made for the gods; and this solemnity was called *lectisternium*, because on this occasion they spread tables, and placed beds around them, on which their heavenly guests were to lie and eat.

LECTURERS, in England, are an order of preachers in parish churches, distinct from the rector or vicar. They are chosen by the vestry, or chief inhabitants of the parish, and are usually the afternoon preachers.

LEDGER, the principal book wherein merchants enter their accounts. See BOOK-KEEPING.

LEDUM, wild rosemary, in botany, a plant which grows naturally in moist places in several parts of England: it rises with a slender shrubby stalk, dividing into many branches, which are furnished with narrow leaves: the flowers come out in clusters at the ends of the branches, each having five oval hollow petals, and ten stamina: the fruit is a roundish capsule, with five cells, which are filled with small narrow pointed seeds.

LEE, in the sea language, that part of the hemisphere to which the wind bloweth, in opposition to the weather or windward side. This expression however is only used in a ship, when the wind crosses the line of her course at a greater or less angle; and hence

*Under the LEE* implies farther to lee-ward, or

farther from that part of the horizon from which the wind bloweth, as

*Under the LEE of the Shore*, i. e. at a short distance from that shore which lies to the wind-ward, or from the land where the wind blows from. This phrase is commonly used to express the situation of a ship or boat which may be anchored, or sailing under the weather-shore, where there is always smoother water and less danger of heavy seas than at a great distance from it.

*The Land appears under our LEE*, i. e. at some distance from a ship on that side to which the wind bloweth, as it thwarts her way: and hence

LEE-LARCHES, the sudden roll which a ship makes to lee-ward in a high sea, when a large wave strikes her, and bears her weather-side violently up, which depresses the other in proportion.

LEE-SIDE is the side of a ship which is farthest from the wind, as opposed to the weather-side, which is nearest to it.

Thus, admit a ship to be sailing northward with the wind at west, then her starboard, or right side, is the lee-side, and the larboard, or left, the weather-side.

To LEE-WARD, towards that part of the hemisphere which lies under the lee, or to which the wind bloweth.

LEE-WARD-SHIP, a ship that, going close-hauled, loses much ground, and deviates further to lee-ward from her course than common. See the article CLOSE-HAULED.

LEE-WAY is the angle that the rhumb-line, upon which the ship endeavours to sail, makes with the rhumb upon which she really sails.

This is occasioned by the force of the wind, or surge of the sea, when she lies to the windward, or is close hauled; which causes her to fall off and glide side-ways from the point of the compass she capes at. Thus, let *N E S W* (plate LXV. fig. 5.) represent the compass, and suppose a ship at *C* capes at, or endeavours to sail upon the rhumb *C a*, but by the force of the wind and surge of the sea she is obliged to fall off, and make her way good upon the rhumb *C b*; then the angle *a C b* is the lee-way: and if that angle be equal to one point, the ship is said to make one point lee-way; or if equal to two points, the ship is said to make two points lee-way, &c.

The quantity of this angle is very uncertain; because some ships, with the same quantity of sail, and with the same gale, will make more lee-way than others; it depending much upon the mould and trim of the ship, and the quantity of water that she draws. However, the common allowances made for lee-way, are these: 1. If the ship be close hauled, has all her sails set, the water smooth, and a moderate gale of wind, she is supposed to make little or no lee-way. 2. If it blow so fresh, as to cause

cause the small sails to be handed, it is usual to allow one point. 3. If it blow so hard, that the tops must be close reefed, the ship then makes about two points lee-way. 4. If one top-sail must be handed, it is common to allow two and three-quarter or three points lee-way. 5. When both top-sails must be handed, they allow about four points lee-way. 6. When it blows so hard as to occasion the fore course to be handed, the allowance is between five and a half and six points. 7. When both main and fore courses must be handed, then six, or six and a half points must be allowed for her lee-way. 8. When the mizzen is handed, and the ship is trying a-hull, she then makes her way good about one point before the beam, that is, about seven points lee-way.

Though these rules are such as are generally used, yet as the lee-way depends much upon the mould and trim of the ship, we shall here give the method of ascertaining it by observation; thus let the ship's wake be set by a compass in the poop, and the opposite rhumb is the true course made good by the ship; then the difference between this and the course given by the compass in the binnacle, is the lee-way required. If the ship be within sight of land, the lee-way may be exactly found by observing a point of the land which continues to bear the same way; for the distance between the point of the compass it lies on, and the point the ship capes at, will be the lee-way. Thus, suppose a ship at C (fig. 6.) is lying up at N b W, towards A; but instead of keeping that course, she is carried on the NNE line CB, and consequently the point B continues to bear always the same way from the ship: here it is evident, that the angle ACB, or the distance between the N b W line that the ship capes at, and the NNE line that the ship really sails upon, will be the lee-way. See the articles COMPASS, COURSE, JOURNAL, &c.

LEECH, *Hirudo*, in zoology. See the article HIRUDO.

LEECH of a Sail, the perpendicular or upward sloping-edges of a square, oblong, or triangular sail; in a square or oblong sail, the leeches are those which are perpendicular, as opposed to the upper-edge, which is called the head, and to the lower, which is called the foot of the sail. In triangular sails, when there are only three sides, two of them are called the fore and after-leeches, and the third, which is the lower-edge, the foot.

LEECH-LINE, one of the brails of the main-sail and fore-sail, or one of those cords which draw them together in a lump, when they are to be furled or reefed. See the articles BRAIL and FURL.

The leech-line is so called from its being fastened to the sail in or near the middle of the leech.

LEECH-ROPE, the rope to which the leech of the sail is sewed. See the article BOLT-ROPE.

LEEK, a garden plant, called by botanists porrum. See the article PORRUM.

Leeks are commonly sown along with onions; the onions growing up first are pulled up, so that the leeks have room to grow to their full size.

LEER, in glass-making, a furnace where the vessels are allowed to cool by degrees. See GLASS.

LEES, the more gross and ponderous parts of liquors, which, being separated by fermentation, fall to the bottom.

A spirit of a very agreeable flavour is obtained, by the common process of distillation from wine lees; and as this flavour depends greatly on the essential oil of the lees, care should be taken to bring it over with the spirit. In order to this, the solid lees must be steeped in fix or eight times their own weight of water, and well stirred at times, before they are put into the still. See DISTILLATION.

LEET, *Leta*, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the crown, from whence it derived to inferior persons. See COURT-LEET.

LEG, *Crus*, in anatomy, includes the whole of the lower extremities, from the os innominatum to the toes, being commonly divided into thigh, leg, and foot. See the articles THIGH and FOOT.

LEGACY signifies any thing that is particularly given or bequeathed by a last will and testament. See WILL and TESTAMENT.

LEGATE, a cardinal or bishop, whom the pope sends as his ambassador to sovereign princes. See AMBASSADOR.

There are three kinds of legates, viz. legates a latere, legates de latere, and legates by office, or legati nati: of these the most considerable are the legate a latere, the next are the legates de latere. See the article A LATERE.

Legates by office are those who have not any particular legation given them, but who by virtue of their dignity and rank in the church become legates; such are the archbishops of Rheims and Arles; but the authority of these legates is much inferior to that of the legates a latere.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGEND, an idle or ridiculous story told by the Romanists concerning their saints, and other persons, in order to support the credit of their religion.

LEGER-LINE, in music, one added to the staff of five lines, when the ascending or descending notes run very high or low: there are sometimes many of these lines both above and below the staff, to the number of four or five.

LEGGIARDO, or LEGGIARDEMENTE, in music,

Fig. 1. Lens.

Fig. 2. Lens.

Fig. 3. Locus.

Fig. 5. Logarithmic Spiral.

Fig. 4. Logarithmic Curve.

Fig. 6. Maximum.

Fig. 7.  
Maximum.

*Fig. 8. Maximum.*

**music**, signifies to play or sing in a lively, brisk, and gay manner.

**LEGION**, in Roman antiquity, a body of foot which consisted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thousand; though Plutarch assures us, that after the reception of the Sabines into Rome, he encreased it to six thousand. The common number afterwards, in the first times of the free state, was four thousand; but in the war with Hannibal it arose to five thousand, and after this it is probable that it sunk again to four thousand, or four thousand two hundred, which was the number in the time of Polybius.

**LEGISLATOR**, or **LAW-GIVER**, he who frames laws for any state or kingdom.

**LEGITIMATION**, an act whereby illegitimate children are rendered legitimate. See the article **BASTARD**.

**LEGUME**, *Legumen*, among botanists, denotes a pericarpium of an oblong compressed figure, formed of two valves, joined by a visible suture both on the upper and under parts, and having the seeds affixed to the upper limbs of the two valves, in an alternate order.

**LEGUMINOUS**, an appellation given to all plants whose fruit is a legume.

**LEMMA**, in mathematics, a previous proposition laid down, in order to clear the way for some following demonstration; and is prefixed either to the theorems or problems.

Thus, to prove a pyramid one third of a prism of the same base and height with it, as the demonstration is difficult, this lemma may be premised, which is proved in progression, "That the sum of the series of the squares of numbers in arithmetical progression, beginning from 0, 1, &c. is always subtriple of the sum of as many terms equal to the greatest; or is always one third of the greatest term multiplied by the number of terms." And, in like manner to find the inflection of any curve, this lemma is first premised, "That a tangent may be drawn to the given curve in a given point;" and so in physics, medicine, &c.

**LEMNA**, duck-weed, in botany, a genus of plants, producing distinct hermaphrodite and female flowers: neither of which have any flower petals: the stamina are two subulated filaments; and the fruit is a globose, unilocular capsule.

**LEMON**, *Limon*, in botany, a genus of trees with large stiff leaves like the citron, without any appendage at the bottom; the flower consists of many leaves, which expand in form of a rose: the fruit is almost of an oval figure, and divided into several cells, in which are lodged hard seeds surrounded by a thick fleshy substance, which, for the most part, is full of an acid juice.

All sorts are propagated by budding or inarching them either on stocks of lemons or citrons produced

from seeds, but they will not readily unite on orange stocks; for which reason the citrons are preferable to either oranges or lemons for stocks, as they readily join with either sort; and being of larger growth, cause the buds of the other sorts to be much stronger than if they were on stocks of their own kind.

The culture of the lemon is the same with that of the orange-tree, with this difference only, the former being hardier than the latter, will consequently bring their fruit to maturity with us much better than the orange will, and therefore require to have a greater share of fresh air in winter; for which reason they should always be placed near to the doors or windows of the green-house: and in some curious gardens these trees have been planted against walls, where, by covering them with glasses in winter, and protecting them from severe frosts, they have produced plenty of large fruit: as these trees do generally produce stronger shoots, so they require more water to be given them than the orange; but as to the tender sorts, they must be treated with a little more care, otherwise their fruit will fall off in winter, and come to nothing. See **ORANGE**.

**LEMONADE**, a liquor prepared of water, sugar, and lemon or citron-juice: it is very cooling and grateful.

**LAMURIA**, a festival of the ancient Romans, solemnized on the ninth of May, to pacify the manes of the dead, who were the lemures or phantoms that came in the night to torment the living.

**LENITIVE MEDICINES**, among physicians, those of a mild, softening, and relaxing nature, and destitute of all acrimony.

**LENS**, in dioptrics, a small oblong glass like a lentil; it is a medium terminated on one side by a spherical surface, on the other by a surface either plain or spherical. And of these there are five sorts. The first, as A (plate LXV. fig. 7.) is plain on one side, and convex on the other; the second, B, convex on both sides; the third plain on one side and concave on the other, as C; the fourth, D, concave on both sides; the fifth convex on one side and concave on the other, as E, which is by some called a meniscus.

The axis of a lens is a line passing perpendicularly through both its surfaces: thus the line FG is an axis common to all the five.

Lenses are distinguished into two general kinds, convex and concave: the first and second lenses are considered as convex; the third and fourth as concave: the last, if its convexity is greater than its concavity, is looked upon as convex; if on the contrary, it is considered as concave.

A lens is always supposed to consist of a medium denser than the circumambient one, unless where the contrary is expressed.

When parallel rays fall upon the surface of a convex

vex lens, they are refracted towards each other in passing through it, and thereby collected to a focus on the other side.

To explain this, let us trace the progress of a ray, as AB (*fig. 8.*) through the convex lens CD EH, whose axis is IK. Let L be the center of the first convexity CDE, and M that of the other CHE: and let this ray AB be parallel to the axis; through B draw the line LN, which will be perpendicular to the surface CDE at that point. The ray AB in entering the denser substance of the lens will be refracted towards the perpendicular, and, therefore, proceed, after it has entered the surface at B, in some direction inclined towards the axis, as BP. Through M, the center of convexity of this surface, and the point P, draw the line MR, which passing through the center will be perpendicular to the surface at P, and the ray now entering a rarer medium, will be refracted from the perpendicular into some direction at PF. In like manner and for the same reasons, the parallel ray ST on the other side the axis, and also all the intermediate ones, as XZ, &c. will meet in the same point, unless the rays AB and ST enter the surface of the lens at too great a distance from the axis IF, the reason of which has already been fully explained. See REFRACTION.

The point F, where the parallel rays AB, SF, &c. are supposed to be collected by passing through the lens CE, is called the focus of parallel rays of that lens.

If the rays converge before they enter the lens, they are then collected at a point nearer to the lens than the focus of parallel rays. If they diverge before they enter the lens, they are then collected in a point beyond F; unless they proceed from a point on the other side at the same distance with the focus of parallel rays, in which case they are rendered parallel. If they proceed from a point nearer than that, they diverge afterwards, but in a less degree than before they enter the lens.

If the lens is plain on one side and convex on the other, the rays are refracted the same way, but in a less degree.

Had the rays AB, ST, proceeded from a radiant point on one side the lens, and been collected in a focus on the other; then if they should be supposed to proceed from that focal point as from a radiant, and pass through the lens the contrary way, they would be collected in that point which was the radiant in the other case: and the nearer the radiant point is to the lens, the farther is the focus from it on the other side, and vice versa.

If the rays AB, CD, EF, &c. (*fig. 9.*) be parallel to each other, but oblique to GH, the axis of the lens IK, or if the diverging rays CB, CF, proceed as from some point, C, which is not situated in the axis of the lens, they will be collected

into some point, as L, not directly opposite to the radiant C, but nearly so: for the ray CD, which passes through M, the middle of the lens, and falls upon the surface of it with some obliquity, will itself suffer a refraction at D and N; but then it will be refracted the contrary way in one place to what it is in the other; and these refractions will be equal in degree, if the lens has an equal convexity on each side, as we may easily perceive, if we imagine ND to be a ray passing out of the lens both at N and D; for it is evident that the line ND has an equal inclination to each surface at both its extremities. Upon which account the difference between the situation of the point L and one directly opposite to C is so small, that it is generally neglected; and the focus is supposed to be in that line, which a ray, that would pass through the middle point of the lens, were it to suffer no refraction, would proceed in.

All which is sufficiently clear, from what is said under the article REFRACTION.

When parallel rays fall upon a concave lens, they are refracted from each other in passing through it, and thereby made to diverge, proceeding as from an imaginary focus on the first side of the lens.

In order to comprehend this, let ABCD (*plate LXVI. fig. 1.*) represent a concave lens, EF its axis, GH the radius of the first concavity, IK that of the second; produce GH to L, and let MG be a ray of light entering the lens at the point G. This ray, being refracted towards the perpendicular GL, will pass on to some point, as K, in the other surface, more distant from the axis than G, and being there refracted from the perpendicular IK, will be diverted farther still from the axis, and proceed in the direction KN as from some point at O on the first side of the lens. In like manner other rays, as PQ, parallel to the former, will proceed after refraction at both surfaces as from the same point O; which upon that account will be the imaginary focus of parallel rays of this lens.

If the rays diverge before they enter the lens, their imaginary focus is then nearer the lens than that of the parallel rays. If they converge before they enter the lens, proceeding towards some distant point in the axis at E, they are then rendered less converging; if they converge to a point at the same distance from the lens with the focus of parallel rays, they then go out parallel; if to a point at less distance, they remain converging, but in a less degree than before they entered the lens.

When the rays enter the lens diverging, the nearer their radiant point is to it, the nearer also is their imaginary focus after refraction, and vice versa.

If the lens is plain on one side and concave on the other, the rays suffer a like refraction in each case, but in a less degree.

The

LEO

J. Lodge Sculp

The truth of what has been said, concerning the passage of rays through a concave lens, is easily deduced from the laws of refraction.

But the method of determining the exact focal distance of lenses, is to be had from the propositions laid down and demonstrated in the article REFRACTION, which see.

Thus the progress of the rays, after their refraction at the first surface where they enter a lens, is had by one of those which determines the focal distance of rays entering a denser medium of such form: and their progress, after their refraction at the other surface where they go out, is had by computing what progress rays, moving in the direction they are found to have after their entrance at the first surface, will acquire by being refracted at the other; which is to be effected by one who determines the focal distance of rays passing out of a denser medium of like form with that of the lens.

When a ray passes through a medium, terminated by two plain and parallel surfaces, it is refracted one way in going out of the second, as much as it was the other in entering the first; and, therefore, proceeds afterwards, not in the same direction, but in one which is parallel to that which it had before.

Thus, if the ray AB (*fig. 2.*) enters the denser medium CDEF terminated by the parallel surfaces CD and EF, it is refracted at B towards the perpendicular BI, proceeding to a point at G, where it is as much refracted from the perpendicular GK in going out, and proceeds in the direction GH, not the same, but parallel to the former ABL.

LENT, a solemn time of fasting in the Christian church, observed as a time of humiliation before Easter, the great festival of our Saviour's resurrection.

Those of the Romish church, and some of the

protestant communion, maintain, that it was always a fast of forty days, and as such, of apostolical institution. Others think, it was only of ecclesiastical institution, and that it was variously observed in different churches, and grew by degrees from a fast of forty hours, to a fast of forty days. This is the sentiment of Morton, bishop Taylor, du Moulin, Daillé, and others.

The Christians of the Greek church observe four Lents; the first commences on the fifteenth of November, or forty days before Christmas; the second is the same with our Lent; the third begins the week after Whitsuntide, and continues till the festival of St. Peter and St. Paul; and the fourth commences on the first of August, and lasts no longer than till the fifteenth. These Lents are observed with great strictness and austerity; but on Saturdays and Sundays they indulge themselves in drinking wine and using oil, which are prohibited on other days.

LENTA FEBRIS, the slow fever. See the article FEVER.

LENTIGO, FRECKLES, in medicine. See the article FRECKLES.

LENTISCUS, the lentisk or mastich-tree, in botany, a genus of trees, very nearly allied to the terebinthus, or turpentine-tree, in its characters, but differing in that the leaves are pinnated; but there is no single leaf to terminate the end of each compound one. See the article MASTICH.

LEO, the lion, in zoology. See LION.

LEO, in astronomy, one of the twelve signs of the zodiac, the fifth in order, containing, according to Ptolemy, thirty-two stars; according to Tycho, thirty-seven; and in Mr. Flamsteed's, ninety-four. The latitudes and longitudes of which are as follow. See plate LXVII.

Names and situations of the stars.

|                                                   | Gen | Longitude. |    | Latitude. |    | Magnit. |

LEONINE VERSES, such as rhyme at every hemistich, the middle syllable of each verse corresponding to the last one.

LEONTICE, in botany, a genus of plants whose flower consists of six oval acute petals, with six slender filaments topped with erect antheræ: the fruit is a large inflated berry, with one cell, containing a few globular seeds.

LEONTODON, in botany. See the article DANDELION.

LEONURUS, lion's-tail, in botany, a genus of plants whose flower is monopetalous and ringent, with four stamina, two of which are longer than the others: there is no pericarpium; but the seeds, which are oblong and angular, are contained in the bottom of the cup.

LEOPARD, a beast of prey, with the spots on

the upper part of the body round, and the lower ones virgated. It is a very nimble, as well as fierce animal, so that scarce any thing escapes it.

Authors call the male purdus, and the female panthera.

LEOPARD'S BANE, doronicum, in botany. See the article *Leopard's BANE*.

LEPIDIUM, dittander, in botany, a genus of plants whose flower is detrapetalous and cruciform, with six subulated stamina: the fruit is a compressed spear-shaped pod, containing oblong seeds.

The common dittander, which grows wild in many places in England, has a very hot acrid taste, like pepper; it is said to incite gross humours, opening obstructions of the liver and spleen, and is accounted a great antiscorbutic: when the leaves are eaten in the morning, fasting, they excite the appetite

tite and help digestion. Some affirm, that the powder of the dried leaves, given in wine to half an ounce, in a morning, fasting, is excellent in the dropsy.

**LEPIDOPTERA**, in zoology, an order of insects, with four wings, which are covered with imbricated squamulæ: add to this, that the mouth is commonly spiral.

Under this order, are comprehended the butterflies and phalænæ, or moths.

**LEPROSY**, *Lepra*, in physic, a higher degree of cutaneous disorder than an itch, the same with *lepra arabum*. See **ITCH**, **IMPETIGŌ**, and **ELEPHANTIASIS**.

The word is derived from the Greek *λεπρα*, signifying the same, and that from *λεπρος*, a scale.

There is a wide difference between the itch and leprosy, and that ulcerous disorder in which white fordid ulcers, seizing principally the muscular parts, such as the back, arms, thighs, &c. discharge a putrid sanies, and sometimes appearing in one limb, and sometimes in another, often continue for many years. Large quantities of worms are also found lodged within these ulcers, so that they can hardly be extirpated.

The *lepra* and *elephantiasis* are diseases nearly alike.

The method for the cure of these and such like malignant disorders, is to discharge the mass of corrupt, glutinous, acrid humours, by sufficient bleeding and abstinence, by purges both gentle and drastic, and then by a proper regimen. But if the growing and refractory state of the disease raises a suspicion of malignity, there are no remedies more powerful, if the patient's strength permit, than mercury, and its preparation. Some make an unguent of live mercury thoroughly extinguished with pomatum, adding flowers of sulphur and camphire, with which the joints, ancles, &c. are to be well rubbed. But others choose a better and safer method of using mercury internally; whilst, by a previous preparation of the body, by alteratives, correctors, and evacuants, *mercurius dulcis*, with double the quantity of crabs-eyes, and diaphoretic antimony, is duly exhibited. This intention is also answered by *mercurius solaris* and *jovialis*, of which a few grains, with conserve of roses, may be exhibited every morning, drinking in bed, after it, a pint of some proper decoction. Each of these methods require a very temperate air, a spare diet, and abstinence from pinguious or boiled flesh and acids.

But if the patient be either an infant, or too old, both the ancients and most judicious of the moderns have greatly extolled preparations of milk, especially asses milk, the whey of cows and goats milk, and milk mixed with water.

Whenever these exanthematous disorders are supported by a scorbutic lues, or hypochondriac affection, a much greater advantage will be procured,

when the milk diet is so managed as to alleviate the other disorder with which they are complicated: for which purpose, the best way is the due use of medicinal waters, especially those of a temperate kind, impregnated with a saline and spirituous principle. But if such waters cannot be had, the end will be best answered by a decoction of such herbs as depurate the blood, and are particularly destined to these disorders, with milk or whey, both sweet and somewhat sour. *Hoffman*.

**LEPUS**, the hare, in zoology. See **HARE**.

**LEPUS**, in astronomy, a constellation of the southern hemisphere; comprehending twelve stars, according to Ptolemy; thirteen, according to Tycho; and nineteen in the Britannic catalogue.

**LESSONS**, among ecclesiastical writers, portions of the Holy Scripture, read in Christian churches at the time of divine service.

**LETHARGY**, *Lethargus*, in physic, a kind of disorder, wherein the person affected labours under a heavy and perpetual sleep, with scarce any interval of waking.

The word is derived from the Greek *λεθη*, sleep, and *αργος*, slothful.

There are several species of this disorder; the chief are coma vigil, coma somnolentum, carus, and a lethargy. See **COMA**, **CARUS**, &c.

**LETHE**, in the ancient mythology, one of the rivers of hell, signifying oblivion or forgetfulness; its waters having, according to poetical fiction, the peculiar quality of making those who drank them entirely forget every thing that was past.

**LETTER**, *Litera*, a character either in print or writing, which men have agreed on to signify something, by joining of which they make their thoughts known to one another.

The alphabet of every language consists of a certain number of letters or characters, which have a different sound, form, and signification. See **ALPHABET**.

The articulation of words, or formation of the several letters, begins when the breath has passed the throat; and is almost performed by the nostrils, mouth, tongue, and lips.

Some say that Fohi, first king among the Chinese, and 2950 years before Christ, invented letters, having writ in that language a book called *Yexim*. Others think, from mummies and obelisks, that hieroglyphics were the first manner of writing, they being prior to Moses, as most of the obelisks and pyramids were made while the Israelites were in Egypt. The Chaldeans or Phœnicians, it is very likely, were the masters of the Egyptians; whence it was, that those letters were called Phœnician by the Greeks: yet, according to Diodorus Siculus, they only changed the form of letters.

Pliny will have the most ancient letters to have been the Assyrian, and that Cadmus, about two hundred and fifty years before the Trojan war, brought

brought sixteen of them from Phœnicia into Greece, namely, A, B, C, D, E, F, I, L, M, N, O, P, R, S, T, U, to which Palamedes, during the Trojan war, had added four, Θ, Ξ, Φ, Υ.

Simonides, Evander, and Demaratus, were the first that brought letters into Italy.

The Hebrews made a division of their letters into guttural, viz. *a, b, ch, gn*, or *aleph, be, cheth, hain*; dental, as *z, s, r*, *zain, tsadde, resh*; labial, *b, m, n, p*, *beth, mem, vau, phe*; and those of the tongue, *d, t, l, n*, or *daleth, tau, lamed, nun*; and palatal, as *g, i, c, k*, *ghimel, jod, caph, coph*.

The letters F, G, H, K, Q, X, Y, Z, were formerly unknown to the Romans. One letter was intended to signify only one sound, and not as at present, now to express one sound, and then another, which has introduced that confusion which has rendered the learning of our modern tongue extremely difficult.

Grammarians distinguish their letters into vowels and consonants; into mutes, diphthongs, liquids, and characteristics. Printers distinguish their letters into capital, majuscule, initial, or upper-case letters, which serve for the titles of books, &c. and minuscule, small or lower-case letters, which are again divided into pearl, nonpareil, pica, and great canon.

Letters, again, are of various sizes, each of which are sometimes cast with the Roman, sometimes Italic, sometimes an English, or black letter face. There are also bodies with the Greek, Hebrew, Arabic, the music face, &c.

A set or fount of any of these sizes includes current letters, capitals, numeral figures, points, spaces, &c. See FOUNT.

Letters are the elements of grammar; an assemblage of these composes syllables, of those words, and of these sentences.

Numeral LETTERS, those used instead of cyphers, in order to express numbers, as C, D, I, L, M, V, X.

LETTER also denotes the same with epistle, a writing addressed to any person.

LETTER of Attorney, a writing authorising any person to do the same lawful act for another, as to give seizin of lands, receive debts, sue a third person, &c.

LETTER of Credit, among merchants, is a letter wrote by a merchant or banker to his correspondent abroad, requesting him to credit the bearer as far as a certain sum. See CREDIT.

LETTER of Licence, an instrument or writing granted by a person's creditors, allowing him a certain time for the payment of his debts; by which means, he is enabled to prosecute his business, without fearing an arrest.

LETTER of Mart, or Marque, a letter granted to one of the king's subjects, under the privy seal, empowering him to make reprisals for what was for-

merly taken from him by the subjects of another state, contrary to the law of mart. See MARQUE.

Monitory LETTERS. See MONITORY.

LETTERS-PATENT, or OVERT, are writings sealed with the great seal of England, so called, because they are open with the seal affixed to them. These are granted to authorise a man to do, or enjoy, what of himself he could not do. See the article PATENT.

Pacific LETTERS, *Litteræ Pacificæ*, in church history, testimonial letters given by the bishop, or chorepiscopus, to their priests, when they had occasion to travel abroad, certifying that the bearer was a catholic, and in communion with the church.

Paschal LETTER, a letter written by the pope to all metropolitans, to inform them on what day Easter was to be celebrated.

LETTUCE, *Lactuca*, in botany, a well known genus of plants, the flower of which is compound and imbricated, containing a number of hermaphrodite corollulæ, which are monopetalous, ligulated, and truncated, and indented at the end in four or five parts: the seeds are oblong, acuminate, and crowned with down, and placed in the cup.

There are several sorts of lettuce cultivated in gardens for culinary purposes, as the cabbage-lettuce, brown Dutch, imperial, white cos, black cos, green cos, &c. They are all sown at different seasons of the year, whereby there is a continual supply; but the most esteemed sort is the cos: these should be protected in winter with glasses, otherwise they are liable to be destroyed in very wet or frosty weather. In March they may be transplanted in the open ground, where they may remain till they are cabbaged, and then they are fit for use; but if they are not inclinable to turn in, they should be tied round their tops with bafs, &c. which will blanch and make them tender.

Lettuces, in general, are easy of digestion, they abate the acrimony of the humours, and quench thirst; for which reason they are frequently used in summer season: many take them to be anodyne, and to procure sleep, which is done, not by any narcotic quality, but by relaxing the fibres and temperating the heat of the viscera; they are good in dry constitutions, and help those that are costive.

LEVARI FACIAS, is a writ directed to the sheriff for levying a certain sum of money upon the lands, &c. of a person who has forfeited his recognizance.

LEVATOR, in anatomy, a name applied to several muscles in the body, that serve to raise the parts to which they belong. See ELEVATOR.

LEVATOR *scapulæ proprius*, in anatomy, or rather, according to Winslow, *angularis*, is a long, and pretty thick muscle, about two fingers in breadth, lying above the superior angle of the scapula, along the posterior lateral part of the neck of that bone. It is inserted above in the transverse apophyses

pophyses of the four first vertebra of the neck, by four fleshy branches ending in short tendons. From thence these branches run down a little obliquely, and then uniting are inserted into the superior angle of the scapula and in the edge of its basis, and from thence to the small triangular space, being there covered a little by the rhomboides: it is also covered by the trapezius. By its insertion in the superior angle of the scapula, it moderates the descent of that angle, while the trapezius and serratus major raise the acromium. Afterwards, when these two muscles cease to act, the angularis raises the superior angle, and by that means depresses the acromium.

**LEVATORES Ani**, in anatomy, are muscles that arise fleshy from each side of the ossa pubis, internally within the pelvis, as also from part of the os ischium and sacrum; from those places, like lines drawn from a circumference towards a center, its fibres descend, over the muscoli marsupiales, to their implantation at the lower end of the intestinum rectum in the anus. They chiefly serve to suspend and draw the anus upwards, lest the fæces should be burdensome to the sphincter. In their descent, on each side forwards, from the ossa pubis, they pass close over the glandulæ prostaticæ, in a manner embracing them, whereby they are rendered capable of compressing them; and by a retraction of the anus, at the same time act on the vesiculæ seminales, in order to promote the emission of the semen in coitu. *Cowper.*

**LEUCADENDRON**, in botany, a genus of plants, the general corolla of which is uniform and convex; the partial one of which is oblong, hoary on the outside, and composed of two petals; the upper petal is a long line or unguis, and its limb is lanceolated, undivided, and in its lower part is firmly joined to the lower petal; the lower petal has also a long unguis of a linear figure, but three times as broad as that of the upper petal; the cup, scarce at all altered, serves instead of a pericarpium, and contains a single roundish seed, coronated with hairs.

**LEUCOIUM**, in botany, a genus of plants whose flower is spreading, and divided into six oval petals, joining at their base: the stamina are six very short bristly filaments, topped with oblong quadrangular antheræ: the fruit is a turbinated capsule, formed of three valves, with three cells, which are filled with roundish seeds.

**LEVEL**, an instrument to draw a line parallel to the horizon, whereby the difference of ascent or descent between several places may be found, for conveying water, draining fens, &c.

The word is derived from the Latin, *libella*, the cross beam in a balance, which, to be just, must stand exactly horizontal.

**Air LEVEL**, that which shews the line of level by means of a bubble of air inclosed with some liquor in a glass tube, whose two edges are sealed

hermetically. When the bubble fixes at a mark made exactly in the middle of the tube, the plane where it is fixed is level; otherwise the bubble will rise to one end.

The liquor with which the tube is filled is of oil of tartar, or aqua-secunda; these not being liable to freeze.

**Air LEVEL**, with sights, consists of an air level about eight inches long, and seven or eight in diameter, set in a brass tube, with an aperture in the middle. The tubes are carried in a strong straight ruler, a foot long, at whose ends are fixed two sights exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass, crossing each other at right angles, in the middle of which is drilled a very little hole, through which a point on a level with the instrument is described.

The brass tube is fastened on the ruler by means of two screws; one of which serves to raise or depress the tube at pleasure, to bring it to a level. The top of the ball and socket is rivetted to a little ruler that springs, one end of which is fastened with screws to the great ruler, and the other end has a screw serving to raise or depress the instrument when nearly level.

The following is a more commodious instrument.

**Air LEVEL**, with telescope sights; this level only differs from the last, in that, instead of plain sights, it carries a telescope.

This was invented by M. Huygens; which has this advantage, that it may be inverted by turning the rule and telescope half round; and then, if the hair cut the same point that it did before the turn, it is a proof that the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying upon a parallel to the base or ruler, when there is occasion to take the level of remote objects.

**Artillery-Foot LEVEL**, in gunnery, is in form of a square, having its two legs or branches of an equal length, at a juncture whereof is a little hole, whence hangs a thread and plummet, playing on a perpendicular line in the middle of a quadrant. It is divided into twice 45 degrees from the middle.

This instrument may be used on other occasions, by placing the ends of its two branches on a plane; for when the thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level. To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height, by means of the plummet, whose thread will give the degree above the level.

**Carpenter's and Paviour's LEVEL**, consists of a long ruler, in the middle whereof is fitted, at right angles, another somewhat bigger, at the top of which is fastened a line, which, when it hands over a fiducial line at right angles with the base, shews that

that the said base is horizontal. Sometimes this level is all of one board.

*Gunner's LEVEL*, for levelling cannons and mortars, consists of a triangular brass-plate, about four inches high, at the bottom of which is a portion of a circle, divided into 45 degrees, which number is sufficient for the highest elevation of cannons and mortars, and for giving shot the greatest range: on the center of this segment of a circle is screwed a piece of brass, by means of which it may be fixed or screwed at pleasure; the end of this piece of brass is made so as to serve for a plummet and index, in order to shew the different degrees of elevation of pieces of artillery. This instrument has also a brass-foot, to set upon cannons or mortars, so that when these pieces are horizontal, the instrument will be perpendicular. The foot of this instrument is to be placed on the piece to be elevated, in such a manner, as that the point of the plummet may fall on the proper degree: this is what they call levelling the piece.

*Mason's LEVEL*, is composed of three rules, so joined as to form an isosceles-rectangle, somewhat like a Roman A, at the vertex whereof is fastened a thread, from which hangs a plummet, that passes over a fiducial line, marked in the middle of the base, when the thing, to which the level is applied, is horizontal: but declines from the mark, when the thing is lower on one side than on the other.

*Plumb or Pendulum LEVEL*, that which shews the horizontal lines by means of another line perpendicular to that described by a plummet or pendulum. This instrument consists of two legs or branches, joined together at right angles, whereof that which carries the thread and plummet is about a foot and a half long; the thread is hung towards the top of the branch, at the point; the middle of the branch where the thread passes is hollow, so that it may hang free every where; but towards the bottom, where there is a little blade of silver, whereon is drawn a line perpendicular to the telescope, the said cavity is covered by two pieces of brass, making as it were a kind of case, lest the wind should agitate the thread, for which reason the silver-blade is covered with a glass, that it may be seen when the thread and plummet play upon the perpendicular: the telescope is fastened to the other branch of the instrument, and is about two feet long; having an hair placed horizontally across the focus of the object-glass, which determines the point of the level. The telescope must be fitted at right-angles to the perpendicular. It has a ball and socket by which it is fastened to the foot, and was invented by Mr. Picard.

*Reflecting LEVEL*, that made by means of a pretty long surface of water, representing the same object inverted which we see erected by the eye, so that the point where these two objects appear to

meet, is a level with the place where the surface of water is found. This is the invention of Mr. Mariotte.

There is another reflecting level, consisting of a mirror of steel, or the like, well polished, and placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must make an angle of 45° with the telescope, in which case the perpendicular line of the said telescope is converted into a horizontal line, which is the same with the line of level. This is the invention of Mr. Cassini.

*Water-LEVEL*, that which shews the horizontal line by means of a surface of water or other liquor, founded on this principle, that water always places itself level. See the article FLUID.

The most simple is made of a long wooden trough, or canal, whose sides are parallel to the base, so that being equally filled with water, its surface shews the line of level.

It is also made with two cups fitted to the two ends of a pipe, three or four feet long, about an inch in diameter, by means whereof the water communicates from the one to the other cup; and this pipe being moveable on its stand by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extreme of the pipe with wax or mastic. Into the pipe is poured some common or coloured water, which shews itself through the cylinders, by means whereof the line of level is determined; the height of the water, with respect to the center of the earth, being always the same in both cylinders: this level, though very simple, is yet very commodious for levelling small distances.

*LEVELLING*, the finding a line parallel to the horizon, at one or more stations, and so to determine the height of one place with regard to another. See LEVEL.

A truly level surface is a segment of any spherical surface which is concentric to the globe of the earth. A true line of level is an arch of a great circle which is imagined to be described upon a truly level surface.

The apparent level is a straight line drawn tangent to an arch or line of true level. Every point of the apparent level, except the point of contact, is higher than the true level.

When a proper station for the level has been pitched upon between the two points, the two heights observed at that station must be written down in two columns, namely, under the first column those observed when the eye was from the spring, or towards the point, which may be called

LIBRA.

J. Lodge Sculp.

**LIBATION**, a religious ceremony among the ancient pagans, which consisted in an effusion of liquors poured on the head of the victims prepared for sacrifice.

Libations were also in use among the Hebrews, who poured a tun of wine on the victim after it was killed, and the several pieces of the sacrifice were laid on the altar, ready to be consumed in the flames.

**LIBEL**, injurious reproaches or accusations against a person, written and published in order to expose him to public contempt, hatred, or ridicule.

**LIBEL**, in the law of Scotland, implies an indictment. See **INDICTMENT**.

**LIBELLA**, or **LIBELLULA**, in the history of insects, a genus of four-winged flies, called in English dragon-flies, or adder-flies; the characters of which are, that they are furnished with jaws, the antennæ are short, and the tail terminated by a kind of forceps.

**LIBERATE**, in law, a writ that lies for the payment of a pension, or annual sum, granted under the great seal, being directed to the treasurer and chamberlains of the exchequer.

**LIBERIA**, in Roman antiquity, a festival observed on the sixteenth of the calends of April, at which time the youth laid aside their juvenile habit, for the toga virilis, or habit peculiar to grown men. See the articles **TOGA**.

**LIBERTUS**, in Roman antiquity, a person who from being a slave had obtained his freedom. See **MANUMISSION**.

**LIBERTY**, *Libertas*, in general, denotes a state of freedom, in contradistinction to slavery. See the article **FREEDOM**.

According to Cicero, liberty is the power of living as a man pleases, or without being controlled by another.

In a legal sense, liberty signifies some privilege that is held by charter or prescription.

**LIBRA**, the balance, in astronomy, one of the twelve signs of the zodiac, the sixth in order; so called because, when the sun enters it, the days and nights are equal, as if weighed in a balance.

**LIBRA**, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

**LIBRARY**, an edifice, or apartment, destined for the placing of books; or the books themselves lodged therein.

The word is formed from the Latin *libraria*, which is derived from *liber*, a book.

**LIBRATION**, in astronomy, an apparent inequality in the motion of the moon, by which she seems to librate or waver about her own axis, sometimes from the east to the west, and sometimes from west to east. See the article **MOON**.

**LIBRATION of the Earth** is that motion whereby the earth is so retained in its orbit, that its axis

continues constantly parallel to the axis of the world.

**LICENCE**, in law, an authority given to a person to do some lawful act.

**LICENTIATE**, one who has obtained the degree of a licence.

**LICHEN**, *Cinereus Terrestris*, ash-coloured ground liver-wort, in botany, a species of moss, consisting of roundish, pretty thick leaves, divided about the edges into obtuse segments, flat above, of a reticular texture underneath, fastened to the earth by small fibres; when in perfection, of an ash-grey colour; by age, turning darker-coloured or reddish. It grows on commons and open heaths, spreads quickly on the ground, and is to be met with at all times of the year, but is supposed to be in its greatest vigour about the end of autumn.

This herb is said to be a warm diuretic. It is particularly celebrated as a preservative against the terrible consequences of the bite of a mad dog: an account of the remarkable efficacy, in this intention, of a powder composed of the dry leaves and black pepper, was communicated to the Royal Society by Mr. Dampier, and published in N<sup>o</sup>. 237 of the Philosophical Transactions. This powder was afterwards inserted, in the year 1721, into the London Pharmacopœia, at the desire of Dr. Mead, who had large experience of its good effects, and who declares, that he had never known it to fail, where it had been used, with the assistance of cold bathing, before the hydrophobia began.

**LICTORS**, *Lictores*, in Roman antiquity, the serjeants or beadles who carried the fasces before the superior magistrates: it was also a part of their office to be the public executioners in beheading, scourging, &c.

**LIEGE**, in law, a term sometimes used for liege-lord, or one who owns no superior; and sometimes for liege-man, or one who owes allegiance to the liege-lord. In our statutes, the king's subjects are sometimes called lieges, or liege-people.

**LIEN**, the spleen, in anatomy. See **SPLEEN**.

**LIENTERY**, in medicine, a disorder proceeding from a preternatural smoothness of the intestines, in consequence of which, what is discharged by stool, greatly resembles the aliments, both in colour and substance.

The cause of this disorder, according to Fernelius, is not an obstructed or hindered distribution of the aliments, but a weakness of the first concoction, in consequence of which the aliments pass through the intestines unchanged.

The principal intention of cure in a lientery, according to Etmuller, is to strengthen and corroborate the stomach; which end is most effectually obtained by rhubarb, preparations of coral, and quinces. All the medicines recommended against vomiting, are also proper in this disorder. Wald-

schmidius informs us, that the most-simple and easily prepared stomachics are more beneficial in a lientery, than those of the compound kind. The most proper stomachics, according to that author, are preserved nutmeg, preserved ginger, the white of an egg boiled with vinegar, and wormwood-wine prepared with mastich.

**LIEUTENANT**, an officer who supplies the place, and discharges the office of a superior in his absence. Of these, some are civil, as the lords-lieutenants of kingdoms, and the lord-lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-general of the artillery, lieutenant-colonel, lieutenant of the Tower, lieutenant of horse, foot, ships of war, &c.

**LIFE**, *Vita*, in general, a kind of active operative existence, and conceived to consist in motion.

**LIFE** is used in a more particular sense to signify the duration of an animal's being; or the space of time that passes between its birth and death.

**LIFE-ANNUITIES**. See the article **INTEREST**.

**LIFTS**, in the sea-language, certain ropes that reach from the mast-heads to the yard-arms of a ship, to keep the sail-yards parallel to the deck, or as seamen term it, square by the lifts, i. e. parallel to the horizon, when the ship is upright, or at right angles with the mast.

The lifts are also employed to top the yards, i. e. to lift one yard-arm higher than the other, by drawing in one lift, and slackening the other.

*Topping-LIFT*. See **TOPPING-LIFT**.

**LIGAMENT**, in anatomy, a strong compact substance, serving to join two bones together.

A ligament is more flexible than a cartilage, not easily ruptured or torn, and does not yield, or at least very little, when pulled.

**LIGATURE**, in surgery, is a cord, band, or string; or the binding any part of the body with a cord, band, fillet, &c. whether of leather, linen, &c.

Ligatures are used to extend and replace bones that are broken or dislocated; to tie the patients down in lithotomy and amputations; to tie upon the veins in phlebotomy, or the arteries in amputations, or in large wounds; to secure the splints that are applied to fractures; to tie up the processes of the peritonæum, with the spermatic vessels in castration; and lastly, in taking off warts or other excrescences by ligature. For the manner of using them, see **LITHOTOMY**, **FRACTURE**, &c.

**LIGHT**, *Lux*, in philosophy, certain inconceivable small particles of matter of different magnitudes, which are emitted or reflected from every point in the surface of a luminous body in right lines, and in all directions, with an unparallelled velocity, and whose power and intensity decrease as the squares of the distances increase.

The Greeks, and after them all the barbarous nations, who learned of them to reason and to err, have said from age to age through a long series of time, "Light is an accident, which accident is the act of transparent as transparent; colours are what move transparent bodies. Luminous and coloured bodies have qualities like those they excite in us, according to the maxim, that nothing can give what it has not. In fine, light and colours are a mixture of the hot, cold, dry, and humid; for the humid, dry, cold, and hot, being the principles of all things, colours must necessarily be composed of them." See the article **COLOUR**.

This is the absurd jargon which the professors of ignorance, paid by the public, have made human credulity revere so many ages; which manner of reasoning prevailed almost in all things down to the time of Galileo and Descartes. Even long after them, the same trash, the disgrace of human understanding, subsisted in many schools.

All the pretended philosophers therefore having guessed at nature at a venture through the veil under which she lay concealed, Descartes at length came, and discovered a corner of this great veil. He said, "Light is a fine and subtle matter, diffused universally, that strikes our eyes. Colours are sensations excited in us by God, according to the motions which transmit that matter to our organs." Thus far Descartes was in the right, and ought either to have stopped there, or, in advancing, to have taken experiment for his guide. But he was possessed with a desire of establishing a system. That passion had the same effect on this great man, as passions have on all men; they hurry them beyond their principles.

According to Descartes, the light does not proceed to our eyes from the sun, but in a globulous matter diffused universally, which the sun impels, and which presses upon our eyes as a staff pushed at one end presses the same instant upon another. This appeared plausible, but is not therefore the less false. Descartes, however, was so fully convinced of this principle, that, in his seventeenth letter of the third volume, he positively says, and repeats it, "I confess that I know nothing of philosophy, if the light of the sun is not transmitted to our eyes in an instant." And indeed we must own, that, as great a genius as he was, he knew very little of true philosophy, and wanted the experiments of the preceding age. That age is as much superior to Descartes, as Descartes was to antiquity.

If light were always diffused, and always existing in the air, we should see as clearly in the night as we do in the day; because the sun below the horizon would continually impel the globules on all sides, and the impression equally affect our eyes.

That light is a material substance, and what we properly call body, is not to be doubted; because

we find it something that has motion, or is propagated in time; something that acts upon our bodies, and produces great alterations and changes in their natures and forms. It is something that bodies act upon, by reflecting, inflecting, and refracting it on their surfaces, and in their pores: and it would appear to have weight, and all other sensible qualities of common matter, were it not that the smallness of its quantity renders them entirely imperceptible to us. Nor are we to consider light only as a body, but as the most active principle or most general agent in nature; and it is, perhaps, the true primum mobile, or the spring of motion and action in all other bodies. Were the particles of light to be annihilated, we should see no marks or foot-steps of fire or heat remaining, and therefore no power of motion in bodies; but all things would put on the appearance of lifeless inert matter, rigid and inflexible, as it would be absolutely cold and dark.

The divine wisdom and providence appear, perhaps, in nothing so remarkably as in the extreme subtilty of the particles of light: without this qualification it could not have pervaded the pores of bodies, and so we could have had none of those which we call diaphanous or transparent substances, and every thing but the surface of a body would have been concealed from the sight of mankind. Again, the velocity of a body is always as the quantity of matter inversely; and therefore, the smaller the body, the greater velocity it is susceptible of from the same force; whence it comes to pass that light is thus qualified to be transmitted through immense distances in a small and insensible part of time; which thing was quite necessary, according to the present frame and state of nature.

But lastly, it was absolutely necessary that the particles of light should be so exceeding small, that, when compounded with its velocity, it should produce no sensible force, as it must otherwise have done, and which, therefore, could not have been borne by the tender and delicate texture of the several parts of vegetable and animal bodies. To give an example: the velocity of a particle of light is found to be at the rate of 897600000 feet per second; suppose its matter to be but one millionth part of a grain, then its force to strike an object would be as  $\frac{897600000}{1000000} = 897,6$  feet per second for one grain; or it would strike with the same force that one grain weight would do falling from half the height, viz. through 448,8 feet; which we should find to be very great, was the experiment to be made on the sensible coats of the eye.

Since the weight of bodies is proportioned to the quantity of matter, it follows, that where the latter is diminished indefinitely, the former will be so too; therefore, the weight of light must be insensible to ever so great a quantity of it. Dr. Boerhaave caused a globe of iron, twelve inches in diameter, to be heated red hot, and suspended at the end of a very

exact balance, and counterpoised by weights at the other end very nicely, and thus let it hang till all the particles of heat or light were escaped, when he found the equilibre of the balance no ways altered; which plainly proves the above thesis.

That the particles of light have not only magnitude, but that in different degrees also, is another, and perhaps the most subtile, discovery of the Newtonian philosophy. The comparative terms of greater and lesser are now as applicable to the particles of light, as to any other bodies. This is absolutely proved by the different refrangibility they are found to have in passing through a prismatic figure of glass or water; for the power of the prism detains the issuing particle, and draws it a little towards the surface; and, since this power is the same, it would have the same effect on all the particles of light, if they were all of an equal magnitude, because they have all an equal velocity. But since this effect is different among the particles, some being detained and drawn aside to a greater distance than others, it follows, they must be less in magnitude, to become more subject to the influence of the attracting surface; in like manner as the electric effluvia will act upon and agitate very small and light bodies, much sooner and more easily than they can move those which are larger.

If light were not reflected from every point in the surface of a body in all directions every way, there might be assigned a point of space where a ray of light, from such a point in the surface, does not come; and there the said point of the surface could not be visible: but because the eye can find no point of space in all the visible hemisphere respecting that point, but where it is visible; therefore, a ray of light is reflected from that point to every part of space, from whence a right-line to that point can be drawn.

That the rays of light proceed in a right-lined direction, is evident from hence, that whatever the figure of the body be, if it be held perpendicular to the rays of light, it will always cast a shadow of the same figure against a parallel plane. Thus a circle will produce a circular shadow, a triangle a triangular one, and so on; which plainly shews that the rays of light pass by the extremities of these bodies in right-lined directions, excepting these only which pass contiguous to the edges of the body; for they will be a little inflected, which will cause the extremity of the shadow to be not so distinct and well defined as it otherwise would be; of which we shall take farther notice hereafter.

As all the other affections of light, so that of its velocity was utterly unknown to all the ancient, and most of the modern philosophers, who, before the time of Mr. Romer, were of opinion that the motion of light was instantaneous, or that it was propagated through immense spaces in an instant. But Mr. Romer, and other philosophers about this time,

making

making frequent observations on the eclipses of Jupiter's moons, found that the time of these eclipses did not correspond to the calculations founded upon the astronomical tables; where the times are all calculated for the distance of the center of the sun, and consequently where the eye of the spectator must be supposed to be in viewing the said eclipses, occultations, &c. of Jupiter's moons.

But this, though a sufficient discovery or proof of the progressive motion of light, was yet but an experiment in the gross, and not accurate to determine or define the true rate or velocity which properly belonged to light: the solution of this noble problem was reserved for Dr. Bradley, who by reiterated and certain experiments, observed, that the bright star in the head of Draco, appeared 39" more northerly in September than in March, just the contrary way to what it ought to appear by the annual parallax of the stars, which must arise from the velocity of light bearing some proportion to that of the annual motion of the earth. See the article *ABERRATION of the Stars*.

And hence it has been found, that the velocity of light is 10210 times greater than the velocity of the earth in her orbit. But the velocity of the earth is known, which is about 500,000,000 miles in 365 days, or about 56,000 miles per hour; whence the velocity of light will be found to be such as carries it through the space of 170,000 miles (or 897,600,000 feet) in one second; and, therefore, it will pass from the sun to us in 8' and 13".

If a cannon will throw a ball one mile perpendicular height, or 5280 feet, the velocity with which it goes from the cannon's mouth is the uniform velocity of 10,560 feet per 18 $\frac{1}{4}$ ", which is the time of the perpendicular ascent or descent, and therefore the velocity of the cannon-ball is 578 feet per second. Whence the velocity of light is, to that of the cannon-ball, as 897,600,000 to 578, or as 1,550,000 to 1, nearly.

The doctor found, that the parallax of the fixed stars, instead of amounting to many seconds, as some have deduced from their observations, does not make one second; and from thence it follows, that the above-mentioned star, in Draco, is about 400,000 times farther from us than the sun; and, consequently, that the light takes up above 493"  $\times$  400,000 = 197,200,000 seconds, which is more than six years, in coming from that star to us.

For the properties of reflected and refracted light, see the articles *REFLECTION* and *REFRACTION*.

**LIGHT** is also used to denote the disposition of objects, with regard to the receiving of light: thus, the doors, windows, &c. of houses, are called lights.

For the lights and shades of painting, &c. see *CLARO-OBSCURO*.

**LIGHTER**, a sort of vessel or large boat employed in harbours or rivers, particularly the Thames, to bring goods to and from a ship in the act of lading and delivering the cargo. See *CARGO*.

**LIGHT-HOUSE**, among sailors, a little house erected on a cape, hill, or promontory, near the sea-coast, for the direction of ships which are passing that way: for this purpose it is furnished with great lights at the top, and has always somebody to watch them. As the lights may be seen at a great distance, they are very serviceable in guiding ships which are at a loss to know where they are.

**LIGHTNESS**, or *Levity* of **BODIES**. See the article *LEVITY*.

**LIGHTNING**, in physiology, the bursting of fire from a cloud.

From Mr. Franklin's experiments, it appears, that lightning is only electrical fire drawn off from the clouds; and, in effect, this electricity has been collected, during thunder, in iron bars, or on tin tubes, in many parts of Europe. See *ELECTRICITY*.

Thunder, then, or lightning, is, in the hand of nature, what electricity is in ours; the wonders which we now exhibit at pleasure, are only little imitations of those great effects which frighten us. A cloud prepared by the action of winds, by heat, by a mixture of exhalations, &c. is the electrified body; and watery clouds, or terrestrial matter, the non-electrics which excite it. See the article *THUNDER*.

**LIGULATED**, among botanists, an appellation given to such floscules as have a straight end, turned downwards, with three indentures, but not divided into segments.

**LIGUSTICUM**, lovage, in botany, a genus of plants, the general corolla of which is uniform, and the single flowers consist each of five lanceolated petals, bent inwards at the points: the fruit is naked, oblong, angulated, fulcated, and separable into two parts; and containing two oblong, smooth seeds, plane on one side, and striated on the other.

**LIGUSTRUM**, privet, in botany, a genus of trees, with a funnel-fashioned flower, quadrifid or quinquifid at the limb: the fruit is a globose smooth berry, with only one cell, containing four seeds, convex on one side, and angulated on the other.

**LILAC**, in botany, a genus of trees, otherwise called syringa. See *SYRINGA*.

**LILIACEOUS**, an appellation given to such flowers as resemble that of the lily. See *LILY*.

**LILIO-FRITILLARIA**, a species of fritillary. See *FRITILLARY*.

**LILIO-HYACINTHUS**, a species of scilla or quill. See *SCILLA*.

**LILIO-NARCISSUS**, or *AMARYLLIS*, in botany, a genus of plants with a liliaceous flower, composed

posed of six petals : its fruit is a suboval capsule with three cells, containing a great many seeds.

LILIUM, the lily. See LILY.

LILIUM *Convallium*, lily of the valley. See CONVALLIUM *Lilium*.

LILY, *Lilium*, in botany, the name of a large genus of plants, with a kind of bell-fashioned flower, and is composed of six leaves, which are more or less expanded and bent back. The pistil stands in the center of the flower, and finally becomes an oblong and trigonal fruit, which is divided into three cells, and contains a number of margined seeds, arranged in a double order one on another. To this must be added, that the root is of a bulbous form, and is composed of a number of fleshy scales affixed to an axis.

All sorts of lilies and martagons are propagated by sowing their seeds ; and if the seeds are carefully saved from good flowers, the martagons very frequently afford very beautiful varieties.

The manner of sowing them is this : some square boxes should be provided of about six inches deep, with holes bored in the bottoms to let out the wet ; these must be filled with fresh, light, sandy earth, and the seeds must be sown on them pretty thick in the beginning of August, soon after they are ripe, and covered over about half an inch deep with light sifted earth of the same kind. They should be then placed where they may have the morning sun ; and if the weather prove dry, they must be watered at times, and the weeds carefully picked out. In the month of October, the boxes are to be removed to a place where they may have as much sun as possible, and be secured from the north and north-east winds. In spring the young plants will appear, and the boxes are then to be removed into their former situation ; they should be watered at times during the summer, and in August the smallest roots are to be emptied out of these boxes, and strewed over a bed of light earth, and covered with about half an inch depth of light earth sifted over them ; they must here be watered and shaded at times, and defended from the severity of the winter, by a light covering of straw, or peas-haulm, in the hardest weather. In February, the surface of the bed should be cleared, and a little light earth sifted over it. When the leaves are decayed, the earth should be a little stirred over the roots, and in the month of September following, a little light earth sifted on. In the September of the following year, the roots must be transplanted to the places where they are to remain, and set at eight inches distance, the roots being placed four inches below the surface : this should be done in moist weather. They will now require the same care as in the preceding winters ; and the second after they are transplanted, the strongest roots will begin to flower. The fine ones should then be removed at the proper season into flower-beds, and

planted at great distances from one another, that they may flower strong. *Miller's Gard. Dict.*

The roots of the white lily are emollient, maturing, and greatly suppurative. They are used externally in cataplasms for these purposes with success. The common form of applying them is boiled and bruised ; but some prefer the roasting them till tender, and then beating them to a paste with oil, in which form they are said to be excellent against burns. Gerard recommends them internally in dropsies. The flowers are also used in emollient cataplasms ; and the oil, made by insolation, is of common use in pains and tumours of all kinds.

LILY of the Valley. See the article CONVALLARIA.

LIMB, in a general sense, denotes the border or edge of any thing : thus we say, the limb of a quadrant, of the sun, of a leaf, &c.

LIMB, in anatomy, an appellation given the extremities of the body, as the arms and legs. See ARM and LEG.

LIMBERS, or LIMBER-HOLES, in ship-building, small holes in the lower part of the timbers of a ship, close to the keel ; the purpose of which is to let the water, which may have come in by a leak, have a free passage to the well, where the pumps are fixed to draw it out ; for this purpose every floor-timber is fitted with two of these, viz. one on each side of the keelson.

LIMBER-BOARDS, short pieces of plank which form a part of the ceiling of a ship's floor close to the keelson, and immediately above the limber-holes : they can be occasionally removed to clear the limbers, when they are filled or clogged with any filth, sand, gravel, &c.

LIME, *Calx*, a soft friable substance, obtained by calcining or burning stones, shells, and the like.

LIME-TREE, the English name of the *tilia*. See *TILIA*.

LIMITS of Equations, in algebra, a method of discovering the limits of the root of equations, by which their solutions are much facilitated.

Let any equation be proposed, and having put  $p, q, r, s, t, v$ , &c. for the known quantities of the terms thereof, under their signs changed, viz. that of the second  $p$ , that of the third  $q$ , of the fourth  $r$ , of the fifth  $s$ , and so on. And the signs of the terms being rightly observed, make  $p=a$ ,  $pa+2q=b$ ,  $pb+qa+3r=c$ ,  $pc+qb+ra+4s=d$ ,  $pd+qc+rb+sa+5t=e$ ,  $pe+qd+rc+sb+ta+6v=f$ , and so on, observing the same law in the continuation of the series ; and  $a$  will be the sum of the roots,  $b$  the sum of the squares of each of the roots,  $c$  the sum of the cubes,  $d$  the sum of the biquadrates,  $e$  the sum of the quadrato-cubes,  $f$  the sum of the cubo-cubes, and so on. As in the equation  $x^4 - x^3 - 19xx + 49x - 30 = 0$ , where the known quantity or co-efficient

of

of the second term is  $-1$ , of the third  $-19$ , of the fourth  $+49$ , of the fifth  $-30$ : you must make  $1=p$ ,  $19=q$ ,  $-49=r$ ,  $30=s$ . And there will thence arise  $a=(p=)1$ ,  $b=(p+2q=1+38=)39$ ,  $c=(pb+qa+3r=39+19-147=)-89$ ,  $d=(pc+qb+ra+4s=-89+741-49+120=)723$ : wherefore the sum of the roots will be  $1$ , the sum of the squares of the roots  $39$ , the sum of the cubes  $-89$ , and the sum of the biquadrates  $723$ ; hence the roots of that equation are  $1, 2, 3, \& -5$ , and the sum of these  $1+2+3-5=1$ ; the sum of the squares,  $1+4+9+25$ , is  $39$ ; the sum of the cubes,  $1+8+27-125$ , is  $-89$ ; and the sum of the biquadrates,  $1+16+81+625$ , is  $723$ .

Now, to collect the limits, between which the roots of the equation shall consist, if none is impossible, it will be necessary to observe, that when the squares of all the roots are affirmative, the sum of the squares will be affirmative; and therefore greater than the square of the greatest root; and also that the sum of the biquadrates of all the roots will be greater than the biquadrate of the greatest root, and the sum of the cubo-cubes greater than the cubo-cube of the greatest root. Wherefore, to obtain that limit which no roots can pass, find the sum of the square of the roots, and extract the square root of that sum, this root will be greater than the greatest root of the equation; but to approach the greatest root still nearer, find the sum of the biquadrates, and extract its biquadrate root; and for a third approximation, extract the cubo-cubical root of the sum of the cubo-cubes of the roots.

**LIMITS of a Planet**, its excursion from the ecliptic, or, which is the same thing, the points of its greatest latitude.

**LIMITATION**, in law, signifies a certain space of time allowed for bringing actions in.

**LIMITATION of Estate**, is the length of time an estate is to continue in the possession of a person or family.

**LIMITED PROBLEM**, a problem that admits but of one solution, as to make a circle pass through three given points, not lying in the same right line.

**LIMNING**, the art of painting in water-colours, in contradistinction to painting, which is done in oil-colours. See **PAINTING**.

**LIMON**, the lemon-tree. See the article **LEMON**.

**LIMOSELLA**, in botany, a genus of plants whose flower is monopetalous and campanulated, divided at the top into five segments: the fruit is an ovate unilocular capsule, containing a great many seeds.

**LIMPET**, the English name of a shell-fish, called by authors patella. See **PATELLA**.

**LINE**, *Linea*, in geometry, a quantity extended in length only, without any breadth or thickness.

It is formed by the flux or motion of a period. See **FLUXION**.

There are two kinds of lines, viz. right lines and curve lines.

Right lines are all of the same species, but curves are of an infinite number of different species. We may conceive as many as there may be different ratios between their ordinates and abscissas. See the articles **ABSCISS** and **ORDINATE**.

Curve lines are usually divided into geometrical and mechanical; the former are those which may be found exactly in all their points; the latter are those, some or all of whose points are not to be found precisely, but only tentatively, or nearly.

Curve lines are also divided into the first order, second order, third order, &c. See the article **CURVE**.

Lines considered as to their positions, are either parallel, perpendicular, or oblique, the construction and properties whereof see under **PARALLEL**, &c.

Euclid's second book treats mostly of lines, and of the effects of their being divided and again multiplied into one another.

**LINE**, in geography, the same with equator. See the article **EQUATOR**.

**LINES**, in astronomy, are, 1. Fiducial line, the line or ruler which passes through the middle of an astrolabe, or the like instrument, and on which the sights are fitted, otherwise called alhidada, index, dioptra, and medicinium. See the article **ASTROLABE**. 2. The horizontal line. 3. Isochronal line. 4. Meridian line. 5. Line of the nodes. See the articles **HORIZONTAL**, **ISOCHRONAL**, **MERIDIAN**, and **NODES**.

**LINES**, in perspective, are, 1. Geometrical line, which is a right line drawn in any manner on the geometrical plane. 2. Terrestrial line, or fundamental line, is a right line wherein the geometrical plane, and that of the picture or draught, intersect one another. 3. Line of the front, is any right line parallel to the terrestrial line. 4. Vertical line, the common section of the vertical and of the draught. 5. Visual line, the line or ray imagined to pass from the object to the eye. 6. Line of station, according to some writers, is the common section of the vertical and geometrical planes. Others, as Lamy, mean by it the perpendicular height of the eye above the geometrical plane. Others a line on that plane, and perpendicular to the line expressing the height of the eye. 7. Objective line, the line of an object from whence the appearance is sought for in the draught or picture.

**LINES**, in dialling, are, 1. Horizontal line, the common section of the horizon and the dial-plane. See **DIAL**. 2. Horary lines, or hour lines, the common intersections of the hour-circles of the sphere, with the plane of the dial. 3. Substyler line, that line on which the style or cock of a dial is duly erected, and the representation of such an hour-

hour-circle as is perpendicular to the plane of that dial. 4. Equinoctial line, the common intersection of the equinoctial and plane of the dial.

*Contingent LINE.* See CONTINGENT.

*LINE of Measures* is used by Oughtred, to denote the diameter of the primitive circle in the projection of the sphere in plano, or that line in which the diameter of any circle to be projected falls. In the stereographic projection of the sphere in plano, the line of measures is that line in which the plane of a great circle perpendicular to the plane of the projection, and that oblique circle which is to be projected, intersects the plane of the projection; or it is the common section of a plane passing through the eye-point and the center of the primitive at right angles to an oblique circle which is to be projected, and in which the center and pole of such circle will be found.

*LINE of Direction of the Earth's Axis*, in the Pythagorean system of astronomy, the line connecting the two poles of the ecliptic and of the equator when they are projected on the plane of the former.

*LINE of Direction*, in mechanics, that wherein a body actually moves, or would move, if it were not hindered. It also denotes the line that passes through the center of gravity of the heavy body to the center of the earth, which must also pass through the fulcrum, or support of the heavy body, without which it would fall.

*LINE of Gravitation*, of any heavy body, a line drawn through its center of gravity, and according to which it tends downwards.

*LINE of the swiftest Descent*, of a heavy body, is the cycloid. See CYCLOID.

*LINE of a Projectile.* See PROJECTILE.

*LINEs on the Plain Scale*, are the line of chords, line of sines, line of tangents, line of secants, line of semitangents, line of leagues; the construction and application of which, see under the words SCALE, SAILING, &c.

*LINEs on Gunter's Scale*, are the line of numbers, line of artificial sines, line of artificial tangents, line of artificial versed sines of rhumbs, line of artificial tangents of the meridian line, and line of equal parts; for the construction and application of which, see GUNTER'S SCALE.

*LINEs of the Sector*, are the line of equal parts, or line of lines, line of tangents, line of secants, line of polygons, line of numbers, line of hours, line of latitudes, line of meridians, line of metals, line of solids, line of planes. See the article SECTOR.

*LINEs*, in fortification, are those of approach, capital, defence, circumvallation, contravallation, of the base, &c. See the articles APPROACH, CAPITAL, &c.

To *LINE a Work*, signifies to strengthen a rampart with a firm wall; or to encompass a parapet or moat with good turf, &c.

*LINE*, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked. See ARMY.

*LINE of Battle*, in the marine, the array in which a fleet or squadron of ships of war is formed to engage with an enemy.

In this manoeuvre, the ships are drawn up about one hundred fathoms distant, a-head of each other, the admiral being in the center, whose chief judgment is to form it in a proper disposition and strength throughout, from the van to the rear; in doing which, particular care must be had to make the center strong; for if that is forced or broke through, the battle is looked upon as lost. Here it is to be observed, that in a sea-action the center is made the strongest; whereas in a land-fight it is the weakest; and the wings of an army are the strongest, lest the enemy by forcing a wing, should have the advantage of flanking, and consequently, putting the line in confusion; for the same reason also, the van and rear of a fleet is not put into disorder, because care is taken to make them proportionally strong to resist the enemy; therefore the weakest part of the line will be in the quarters, as supported each way from the center throughout.

The line being thus formed, there ought to be a corps-de-reserve, as many as may be thought necessary, if they can be dispensed with. But first, the line must stretch out the length of the enemy's, if possible, or else they will have the advantage, and by tacking and doubling upon your line, put the van and rear into confusion.

It is a maxim in naval discipline, that a commanding flag-ship should never go out of her way for any ship whatever, unless that ship should be disabled, or that a sudden shift of wind takes her unexpectedly. The reason is self-evident: if the admiral gives way for one, or backs and fills for another's fancy or misconduct, there would be no end to such negligence or oversight; therefore the commanding flag-ship expects that every ship in his fleet will observe and take her motions from him and his seconds, whose distance from the admiral should be a standard for every other ship to follow in that from each other, as near as possible, except when her signal is made to back or fill, or make more or less sail.

The seconds to the commanding flag-ship are particularly to regard her, to move as she does, whether the other ships do or not, or cannot do; for they are called seconds, to guard and attend the admiral's ship.

It is the duty of every officer, as soon as the signal is displayed for the line to croud, if possible, into his station, and not to lie through indolence or negligence, braced to or a-back, but make sail to windward, or bear away to leeward, in order to

form the line immediately, and then each leading ship to mind her tack as the wind is, to lead and give room.

The commanding flag-officer, when his ships are arranged into a line, observes the strength of the enemy's line throughout, and acts accordingly, making more or less sail, or what motion he might think most to his advantage. He is not to take his motion from his leading ship, but upon some particular occasion, signal, notice, or message sent to him.

In a line of battle, the weathermost fleet, or that which has the weather-gage, in the sea language, is generally allowed to have the advantage, although there are several arguments on the other hand, in favour of the lee-side. We shall endeavour to state the mutual advantages.

1. The weather-gage is soonest clear of smoke; and of course, that line can better observe the signals which are spread, than the ships to leeward can, which must have the continuance of both its own and of the enemy longer.

2. If the weather-ships are more in number than the enemy's fleet, they can detach some from their squadron, which bearing down upon the rear of the enemy, must infallibly throw them into disorder.

3. The fire-ships of the weather-line can, when they are ordered, more easily bear down upon the enemy, than those of the lee can ply to windward, which can never be done against a line in action; but the weather fire-ships can bear down against all the resistance that can be made by the enemy.

Advantages of the lee-line.—1. If one, two, or more of the ships to windward should be disabled, they must inevitably drive to leeward, and become a prey to the enemy.

2. The ships of the lee-line can more readily bear away before the wind, and have their places supplied by ships from the corps-de-reserve, in case of being disabled on meeting with any disaster.

3. The line to leeward can keep their ports longer open in a strong wind with a high sea, when those to windward, in all probability, may be obliged to shut the ports of their lower tier of guns, to prevent the water from rushing in between decks, which may be attended with the most fatal consequences.

4. The lee-line can more easily observe the men on the decks of the ships to windward, as they heel, and when the smoke does not intercept their sight: at which time the marines and top-men may easily take aim at, and destroy them with muskets or carabines.

**LINE A-BREAST**, an arrangement in which the whole squadron advances uniformly with all the ships parallel to each other; so that the length of each ship forms a right line with the line a-breast.

See **DIVISION, SQUADRON, and NAVAL Engagement.**

**LINE** in fencing, that part of the body opposite to the enemy, wherein the shoulders, the right arm, and the sword, ought always to be found; and wherein are also to be placed the two feet at the distance of eighteen inches from each other. In which sense a man is said to be in his line, or got out of his line, &c.

**LINE of Demarcation, or Alexandrian LINE**, a meridian passing over the mouth of the river Moragnon, and by the capes Houmas and Mallabrigo, so called from pope Alexander VI. who, to end the dispute between the crowns of Castile and Portugal, about their boundaries, drew an imaginary line on the globe, which was to terminate the pretensions of each. By this partition, the East-Indies fell to the share of the Portuguese, and the West-Indies to the Castilians.

**LINE of the Synodical**, in reference to some theories of the moon; is a right line supposed to be drawn through the centers of the earth and sun: and, if it be produced, quite through the orbits: it is called the line of the true syzygies: but a right line imagined to pass through the earth's center, and the mean place of the sun, is called the line of the mean syzygies.

**LINE**, in genealogy, a series or succession of relations in various degrees, all descending from the same common father.

**Direct line**, is that which goes from father to son; being the order of ascendants and descendants.

**Collateral line** is the order of those who descend from some common father, related to the former, but out of the line of ascendants and descendants: in this are placed, uncles, aunts, cousins, nephews, &c. See **DIRECT** and **COLLATERAL**.

**LINE** also denotes a French measure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot.

**LINES**, in music, the name of those strokes drawn horizontally on a piece of paper, on and between which the characters and notes of music are disposed: their number is commonly five; when another is added, for one, two, or more notes, it is called a ledger-line.

**LINES**, in heraldry, the figures used in armories, to divide the shield into different parts, and to compose different figures. These lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines.

**LINEA Alba**, in anatomy, a white line which runs from the cartilago enfiformis to the os pubis, dividing the abdomen exactly in the middle: and is formed out of the tendons of the oblique and transverse muscles.

It receives a twig of a nerve from the intercostals in each of its digestations or indentings.

**LINEAMENT**, among painters, implies the outlines of a face.

**LINEAR PROBLEM**, in mathematics, such a problem as may be solved geometrically, by the intersection of two right lines: as measuring an inaccessible height by means of two unequal sticks, &c. It is also called a simple problem, and is capable but of one solution.

**LINEN**, in commerce, a well-known kind of cloth, chiefly made of flax. See **FLAX**.

**LINIMENT**, *Linimentum*, in pharmacy, a composition somewhat thinner than an unguent, and thicker than an oil, used for anointing the body in various intentions.

**LINNET**, *Linaria*, in ornithology, a bird of the size of the goldfinch; the head is small and flatted; the eyes are small, and hazel; the beak is conic, very small, and sharp at the point; the head, neck, and back are variegated with a bright brown and white, the breast and belly are pale, but in the male, especially in the summer, there is a redness on the top of the head and all over the breast. This is a singing bird, and sometimes has young ones four times a year, especially if they are taken from the dam before they are able to fly, which may be done four days after they are hatched.

**LINSEED**, the seed of the plant *linum*. See the article **LINUM**.

Linseed bruised and steeped in water, gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtues to it. It is anodyne, attemperating, and of great service in suppressions of urine from inflammation and heat; it envelops the acid salts of the urine, and prevents their vellicating and wounding the tender parts; and in some measure supplies the mucus of the bladder, when abraded and worn off. It is to be given in decoction, or infusion, on these occasions: the infusion is not to be made too thick or mucilaginous, because in that case it loads the stomach, and breeds flatulencies in the intestines. A slight infusion of linseed, by way of tea, is recommended by many as an excellent pectoral; and the seed is a common and very good ingredient in clysters. Externally, this seed, ground to powder, is an excellent emollient; as is also the strong mucilage, made by boiling the seeds along time: the oil drawn from it by expression is of great service in coughs, pleurisies, and many other cases.

**LINSPINS**, in the military art, small pins of iron, which keep the wheel of a cannon, or waggon, on the axle-tree; for when the end of the axle-tree is put thro' the nave, the linspin is put in, to keep the wheel from falling off.

**LINSTOCK**, in the military art, a wooden staff, about three feet long, upon one end of which is a piece of iron, which divides in two,

turning from one another, having each a place to receive the match, and a screw to keep it fast: the other end is pointed, and shod with iron, to stick in the ground. It is used, by gunners, to fire the guns.

**LINT**, *Linum*, the flax of which linen is made. See **FLAX** and **LINEN**.

In surgery, the term lint denotes the scrapings of linen which is used in dressing wounds, and is made up in various forms, as tents, dossils, pledgets, &c. See the articles **TENT**, **Dossil**, &c.

**LINTEL**, in architecture, a piece of timber that lies horizontally over door-posts and window-jambs, as well to bear the thickness of the wall over it, as to bind the sides of the wall together.

**LINUM**, flax, in botany, a genus of plants, the flower of which is infundibuliform, consisting of five oblong petals; its fruit is a globose capsule, divided into ten cells, in each of which is a single acuminate seed. See **FLAX** and **LINSEED**.

**LION**, *Leo*, in zoology, the strongest and fiercest of all quadrupeds.

The head of the lion appears very large in proportion to its body, and is the most fleshy of the heads of all the known animals. Its jaw-bones also are remarkably large. The breast also appears very large, but this is only owing to the great quantity of long hair that covers it, for the sternum is smaller than that of most animals of the same size. The tail, which is very long, appears also of the same thickness all the way, but this is wholly owing to the growth of the hair. The tail itself is largest at the base, and thence goes taper to the point; but the hair being very short near its base, and continuing to grow longer all the way, as that decreases in thickness, is so exactly proportioned in this growth, that it always gives the whole tail this regular appearance.

The lion has fourteen teeth in each jaw, four incisores, four canine, and six molares. The incisores are small; the canine are unequal in size, two being very large and two very small; the large ones are an inch and half long, and are the only ones the ancients allowed to be canine teeth. The molares also are irregular in size, the anterior ones being very small, the others large, and terminated by three or four points, forming a sort of flower-de-luce.

Aristotle, *Ælian*, and others say, that the neck of the lion is all composed of one unjointed bone. It appears indeed very rigid in this creature, but it does not proceed from so strange a cause, but is found owing to this, that the spinose apophyses of the vertebræ of the neck are long, and fastened together by extremely strong and rigid ligaments.

The tongue of the lion is very rough and rigid, being covered with a great number of prominences of a hard matter, resembling that of a cat's claws, and nearly of the same size, the base of each being a round

a round fleshy prominence on the surface of the tongue.

The eyes of the lion are clear and bright, even after the creature is dead. The common observation that this creature sleeps with its eyes open, is founded on this, that it has a very thick membrane lodged in the greater canthus of the eyes, which it can extend over the whole eye upon occasion, as birds do their *membrana nictitans*, and thus will have no occasion to shut its eye-lids, in order to exclude the light. It is very remarkable, that the common cat has all the singular structure of the several parts as the lion has; its claws, feet, tongue and eyes, being of the same kind, and its internal parts bearing as strong a resemblance.

The heart of the lion is greatly larger than that of any other creature of the same size, being six inches long, and four in diameter, in the largest part, and terminating in a very sharp point. The brain is as remarkably small; and upon the comparison of this with the great quantity of brain in a calf, and pursuing the observation through several other creatures, as to the proportion of brain they have, it does not appear that a small quantity of brain is a mark of folly, but usually of great subtlety, and of a cruel disposition. *Mem. pour l'Histoire des Anim.*

**LIONCELLES**, in heraldry, a term used for several lions borne in the same coat of arms.

**LIP**, *Labinum*, or *Labium*, in anatomy, the exterior fleshy covering of the mouth. See **MOUTH**.

The cheeks and lips form the sides and entry of the cavity of the mouth. They are formed in general by the connexion of several fleshy portions, of different breadths, fixed round the two jaws, covered on the outside with the skin and fat, and lined on the inside by a glandulous membrane. Besides this, the lips have a soft spongy substance, which swells and subsides on certain occasions, independently of the action of the muscles; and is mixed with fat.

The arteries which go to the lips are ramifications of the external carotid, and principally of the external and internal maxillary branches. See **ARTERY**.

The veins are ramifications of the external anterior jugular. See **VEIN**.

The nerves of these parts come from the maxillaris superior and inferior, which are branches of the fifth pair; and also from the portio dura of the auditory nerve, or *sympatheticus minimus*, the ramifications of which are spread in great numbers on all these parts and communicate very singularly with the nerves of the fifth pair in several places.

**Hare-LIPS**, in surgery, a disorder in some persons wherein the upper-lip is so divided, as to resemble a hare's lip. This division is sometimes small, at other times it is double, like the letter

M, and then termed the double hair-lip. Besides the deformity caused by this disorder, it hinders infants from sucking, and adults from speaking distinctly. Sometimes this accident happens to the lower lip from the ill treatment of a wound, and this is called the spurious hare-lip; the true kind is born with the infant. The less and more equal the fissure of the hare-lip is, it is generally so much the more easily cured. In some infants, the division of the lip is so large and irregular, that there can be but little hopes of a cure, which may, however, be easily performed on the very same lip, when adult. Sometimes too we meet with a tooth projecting forward into the fissure; in this case it cannot be cured without first taking out the tooth. In a recent hare-lip, or one made by a wound, the cure is to be performed by the knotted future. See the articles **SUTURE** and **WOUND**.

In curing the hair lip, where part of the lip is wanting, no attempt can be made to supply what is deficient, but only to unite those parts which are divided by taking off the skin from the edges of the fissure, and then causing them to unite and grow together, by passing through them two or three needles, made of gold or silver, pointed with steel from the right to the left, beginning with the upper part of the fissure, and inserting them at about a straw's breadth from each other: the surgeon having thus entered the needles, and cleansed the bleeding lips with a sponge, he takes a piece of strong waxed thread or silk, and fastening it about one end of the needle, he winds it over the other end, and back again. Having done this he afterwards secures it by a knot; by this means the edges of the lips are brought close together, and the upper-part or surface kept smooth and even. To heal the wound internally, it is dressed with soft lint dipped in honey of roses, and put between the gums and lip; but this practice can only be followed with adults: the external part of the wound is at the same time dressed with balsam of Peru, or some other vulnerary unguent, covered with lint and compress, and over that a sticking plaster with four heads, two of which are fastened on the left side of the lip, and two upon the right, and the whole secured by a sling or fillet, whose extremities may be fastened about the head, either by a knot or pins. But it must here be observed, that when the fissure appears large and deep, so that the two parts of the lip cannot be easily joined, it will be necessary, before the above operation, to divide the *frænulum* of the upper-lip from the gum, with a pair of scissars, but without wounding the gum, or uncovering the jaw. Though the hæmorrhage is often very plentiful in performing these operations on young infants, yet it is not dangerous, since it prevents an inflammation, and generally ceases after tying the bandages.

The

The dressings ought not to be moved before the third day, unless some accident makes it necessary; and then it must be done with great caution, to avoid separating the parts in contact. If the lips of the wound appear conjoined, three or four days after the operation, you may then venture to draw out the middle needle, when there are three, or the upper one, when there are only two; and two or three days after draw out the other: the cure must be completed by dressing every day, as at first.

**LIPOTHYMIA**, in medicine, the name of a disease usually confounded with the syncope, but really different from it in many particulars.

The lipothymia is a very considerable abolition of the vital and animal faculties, at least to appearance: and the syncope is a plenary or total abolition of them, as far as appears to us at the time. It is easy to see, however, that these are only two different stages of the same distemperature. The lipothymy is sometimes an idiopathic, sometimes a symptomatic disease, and most frequently attends the scurvy, malignant fevers, and other disorders; the syncope differs from death only in degree: and the body being flaccid in this, and growing rigid under the last convulsions in death, is the only distinction of them in extreme cases.

**LIQUIDAMBER**, in botany, a genus of the monoecia class of plants, the male flowers of which are numerous, and grow in a long loose conical amentum; they are destitute of a corolla, being each composed of a four leaved involucre, with a great number of very short stamina. The female are also apetalous, and are placed at the base of the male spike, collected in a globe; these have a double involucre, also a campanulated perianthium, with many protuberances. The fruit is an ovate unilocular capsule, with two valves at top, and collected in a ligneous globe, and contains many oblong pointed seeds.

The liquidamber-tree is a native of several parts of North America, where it rises to the height of forty feet; the leaves are shaped like those of the lesser maple, of a dark green colour, and their upper surfaces shining; the flowers come out in the spring, growing in spikes, and are of a saffron colour.

The planks of this tree being beautifully veined, are often used in America for wainscoting rooms, but it requires a long time to season the boards, otherwise they are apt to shrink.

**LIQUOR MINERALIS ANODYNUS**, is a name given by Hoffman to a liquor of his invention, famous at this time in Germany, and supposed by Burggrave to be made in this manner: take oil of vitriol, and Indian nitre, of each four ounces; distil the spirit gradually from this, by a retort: pour two ounces of the spirit cautiously and suc-

cessively, into fifteen ounces of spirit of wine, highly rectified; distil this, and there comes over a very fragrant spirit: this is to be again distilled, to render it perfectly pure, adding first to it a small quantity of oil of cloves, and a quantity of water, equal to that of the spirit; after this, as soon as the watery vapours begin to rise, the whole process is to be stopped, and the spirit kept alone in a bottle, well corked. This has great virtues as an anodyne, diaphoretic, antiseptic, and carminative. It is not certain that this is the same with Hoffman's, that author never having published his manner of making it; but it appears the same to the smell and taste, and has the same virtues.

**LIQUORICE**, *liquoritia glycyrrhiza*, and *radix dulcis*, a sweet root of considerable use in medicine.

This plant, described by all the botanical authors under the name of *glycyrrhiza vulgaris*, grows to four or five feet high, its stalks are hard and woody, its leaves are small and roundish; and they stand many together on the two sides of a rib, making what authors call a winged leaf. They are viscous to the touch; the flowers are of the papilionaceous kind, small and bluish.

The plant is of the diadelphia decandria of Linnæus, and of the herbæ flore papilionaceo seu leguminosæ of Mr. Ray. Liquorice grows wild in many parts of France, Italy, Spain, and Germany. It is cultivated in great abundance in Yorkshire, and in many other parts of England; and by the good order we keep the soil in, produce better roots, longer, even, and more succulent than are to be had from any other part of the world. The rest of Europe is in great measure furnished by what grows about Bayonne and Saragossa in Spain.

The ground designed for liquorice must be well dug, and dunged the year before, that the dung may be thoroughly rotted in it; and just before it is planted, the earth is to be dug three spades deep, and laid very light. The plants to be set should be taken from the sides or heads of the old roots, and each must have a very good bud, or eye, or otherwise they are subject to miscarry; they should also be about ten inches long, and perfectly sound. The best season of planting them is the end of February, or the beginning of March, and this must be done in the following manner: the rows must be marked by a line drawn across the bed, at two feet distance; and the plants must be set in these by making a hole of their full depth, and something more, that the eye of the root may be an inch below the surface: they must also be set two feet distance from each other in the rows. When this is done, the ground may be sowed over with onions, which, not rooting deep, will do the liquorice roots no injury for the first year. In October, when the stalks of the liquorice are dead, a little very rotten dung

dung should be spread over the surface of the ground. Three years after the time of planting, the liquorice will be fit to take up for use; and this should be done just when the stalks are dead off; for, if taken up sooner, the roots are very apt to shrink greatly in their weight. The roots about London look browner than those which have been propagated in a less rich soil, but then they are much larger, and grow quicker to their size. *Miller's Gard. Dict.*

Liquorice is an excellent medicine in coughs, and all disorders of the breast and lungs. It obviates the sharpness of acrid and salt humours. It is also recommended against disorders of the kidneys and bladder, and is said to take off the sense of pain in many terrible complaints. It is an ingredient in almost all decoctions and ptisans, in which it is esteemed for obtunding acrimony, and for giving the whole a very pleasant taste, and drowning the worst flavour of the other ingredients.

**LIQUORICE Juice**, the inspissated juice of the common liquorice root, and is brought to us in rolls or cakes, covered usually with bay leaves from Spain and Holland, from the first of which places it obtained the name of Spanish juice. It is to be chosen firm, but not tough, hard, and when broken, of a fine shining surface; such as perfectly melts in the mouth, and does not taste of burning, nor leaves any harsh or gritty particles between the teeth.

The manner of preparing it in Spain is this: they take up the roots in the month of July; they clean them perfectly as soon as taken out of the earth, and then hang them up in the air till nearly dry; after this they cut them into thin slices, and boil them in water till the decoction is extremely strong; they then press it hard out, to obtain all the juice they can from the root. They set this decoction by, to settle a little, and when it has deposited its coarsest parts, they pour it off into vessels, in which they evaporate it over a fire, strong at first, but milder afterwards, till it becomes of the consistence of a thick extract; they then let the fire go out, and when the extract is so cool that they can handle it, they take out large parcels of it at a time; and working them well in the hands, they roll them out into long cylindric masses, which they cut out into such lengths as they please; and rolling them over a parcel of half dried bay leaves, they pick up enough of them for a covering, which are in that condition laid in the sun till perfectly dried; there is great nicety required at the end of the evaporation, to get the extract to a proper consistence, without letting it burn. It is this the Spaniards are famous for: a great deal of liquorice juice is made in other places, but it is in a great measure either under-boiled, and consequently soft, or is burnt.

Liquorice juice has the same virtues with the

root it is produced from. It is a very famous remedy among the common people for coughs, and all disorders of the breast and lungs. It is commonly taken alone, holding a small piece of it in the mouth till it gradually melts there; but the more agreeable way of taking it is in the form of lozenges, of which there are many kinds, which it is the basis of; in these it is mixed with other pectoral ingredients, and has the advantage of melting more easily in the mouth than in its own form. It is also an ingredient in the theriaca and some other compositions of the shops.

**LIST**, in commerce, the border of cloth, or of a stuff; serving not only to shew their quality, but to preserve them from being torn in the operations of fulling, dyeing, and the like. See **CLOTH**, &c.

**List** is used on various occasions; but chiefly by gardeners for securing their wall trees.

**List**, in architecture, a little square moulding, otherwise called a fillet, listel, &c. See the articles **FILLET** and **MOULDING**.

**LISTING**, the same as heeling, or inclining to one side. See **HEEL** and **CAREEN**.

**LITANY**, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession.

**LITERATI**, in general, denotes men of learning; but is more particularly used by the Chinese, for such persons as are able to read and write their language, which is remarkably difficult.

**LITHARGE**, a metalline substance, formed of the fume of lead.

The word is Greek, *λιθαργυρος*, which is formed of *λίθος*, a stone, and *αργυρος*, silver, because it is found in furnaces where silver is refined.

This preparation, or, as it may be more properly called, recement of lead, is of two kinds, differing in colour, though in no other quality: the ancients, as well as moderns, observed this difference, and called the one litharge of gold, and the other litharge of silver. This recement of lead is not prepared by a formal process on purpose; it is collected from the furnaces where silver is separated from lead, or from those where gold and silver are purified by means of that metal; but in the furnaces used for either of these purposes, it is generally run into lead again, to serve for the same or other uses. The litharge sold in the shops is produced in the copper works, where lead has been used to purify that metal, or to separate silver from it. Of all the various metalline and mineral substances, which are separated from gold or silver, by means of lead, there is none but copper which remains embodied in and intimately joined with that metal after scorification; the others being either not at all received into the body of it, or, if they are, being either destroyed before scorification; or, finally, if they remain mixed

mixed with it longer, they split and destroy the vessels. The recrement produced from this combination of lead with copper, is our common litharge. It is of a yellower or redder colour, as the fire has been more or less strong; and is always composed of a multitude of thin flakes, resembling the spangles of talc, in those fossils called micæ or glimmers.

The greatest quantities of litharge are brought from Sweden, Germany, and Denmark. Poland furnishes some, as does also England, but the Dantzic kind is esteemed the most valuable. The best litharge is that which is most calcined, and of the liveliest colour. Litharge, on the whole, is properly lead vitrified, either alone or with a mixture of copper.

Litharge is soluble in oil and all other unctuous substance, and thus dissolved, it makes the basis of a great part of the ointments and plasters of the shops. It is drying, abstergent, and slightly astrictive; and hence it is of great use in cleansing ulcers, and disposing them to incarnate.

**LITHOCOLLA**, a cement used by lapidaries for fastening precious stones together. See the article **CEMENT**.

**LITHONTRIPTICS**, medicines which either break, or are supposed to have the virtue of breaking stones in the urinary passes.

The word is derived from the Greek *λίθος*, a stone, and *σπιντω*, to break.

**LITHOPHYTA**, in botany, a subdivision of plants, so called from their approaching to a stony hardness, comprehending the isis, spongia, millepora, tubipora, &c.

**LITHOSPERMUM**, gromwell, in botany, a genus of plants, the corolla of which consists of a single petal of the length of the cup: the tube is cylindric, the limb semiquinifid, obtuse, and erect: there is no pericarpium, but the cup becomes patulous and long, containing four broad, oval, acuminate, and hard seeds.

The seeds of this plant, being the only parts used in medicine, are accounted diuretic. Emulsions are made of them, with dog's grass water.

**LITHOTOMY**, in surgery, cutting for the stone. See the article **STONE**.

The several methods of performing this dangerous operation, according to Heister, are four: the first, and most ancient, is the apparatus minor, called likewise the Celsian or Guidonian method: the second, the apparatus magnus, or Marianus's method; the latter better termed the new, and the former the old method: the third is the apparatus ultus, or hypogastric section, wherein the incision is made at the lower part of the abdomen in the anterior side of the bladder, immediately above the os pubis; whereas in the rest it is made in the perinæum, between the anus and the scrotum: the fourth, and most modern method, was invented towards the

end of the last century, and is termed the lateral operation.

1. The first method is now entirely laid aside, though Heister thinks it practicable on boys under fourteen: the wound of the bladder in this operation, says Sharp, is made in the same place as is now practised in the lateral method; but its being impracticable on some subjects, and uncertain in all others, has made it to be universally exploded.

2. In performing lithotomy by the apparatus major, Mr. Sharp's directions for the situation of the patient are thus. Having laid the patient on a square horizontal table, three feet four inches high, with a pillow under his head, let his legs and thighs be bent, and his heels made to approach his buttocks by tying his hands to the soles of his feet with a couple of strong ligatures; and to secure him more effectually from struggling, pass a double ligature under one of his hams, and carry the four strings round his neck to the other ham: then passing the loop underneath, make a knot by threading one of the single ends through the loop; and thus the thighs are to be widened from each other, and firmly supported by proper persons.

The patient thus situated, Heister directs the operation as follows: the operator, dipping the beak of a sizeable and grooved steel catheter in oil, conveys it through the urethra into the bladder, and being assured there is a stone, turns the crooked part of the catheter in the bladder and urethra towards the left side of the perinæum, but the handle and penis which contains it, towards the right inguen, then delivers it to the assistant, who holds up the scrotum in the other hand; for the crooked convex part of the catheter thus elevated in the perinæum, renders that part of the urethra which is to be divided, sufficiently perceptible both to the sight and touch. He next lays hold of the integuments of the perinæum with the fingers of his left hand, holding in his right the incision-knife, wrapped in linen, as he would do a pen for writing: with this he makes a longitudinal incision downwards, about the middle of the left side of the perinæum near the future, through the fat; then he again feels for the catheter, and afterwards divides the urethra in a direct line downwards, so that the end of the knife may pass into the groove of the catheter. After a proper incision, the surgeon parts with his knife, inserting in the groove of the catheter, if an assistant holds it, the nail of his finger or thumb: then he takes a male conductor, dips it in warm oil, and having passed it through the groove of the catheter and neck of the bladder into the bladder itself, extracts the catheter.

The male conductor being thus passed, a female conductor is introduced upon it, in such a manner as the latter receives the prominent back of the former in its groove, and conveys it safely into the bladder through its neck. After this, the two conductors

ducters are gently separated by their handles, and then a straight forceps, dipt in oil and shut very close, is carefully conveyed into the bladder between the conductors. The forceps, after it is introduced, and the conductors withdrawn, must be opened several times to dilate the wound, and then shut to search for the stone: when the stone is found, they must be opened with both hands, in such a manner that one jaw, if possible, may lay hold under the stone, and the other above it. When the stone is thus intercepted, the forceps, by a gentle motion from side to side, must be brought towards the rectum, and the stone extracted downwards, because the parts dilate and yield more easily that way, while upwards they meet with a resistance from the os pubis: but if it lies concealed in any part of the bladder, and cannot be laid hold of by the forceps, the operator must pass the two first fingers of his left hand into the anus, elevate the stone, and force it into them. If it is situated in the upper part of the bladder, behind the ossa pubis, the inferior part of the abdomen must be pressed downwards by the hand, that it may commodiously be taken hold of, and drawn out by the straight or crooked forceps; and if it is lodged on either side, the crooked instrument is most convenient.

When the stone is too large to be extracted whole, it must be broken by a forceps with teeth, and the fragments to be drawn out one after another. Lastly, if the stone is too large and too hard to be either extracted or broken, a prudent surgeon will desist, and heal the wound, or leave a fistula for the discharge of the urine. The stone being thus extracted, and the bladder cleared, the wound is cleansed with a sponge, the ligatures untied, the patient put to bed, and the wound now dressed with the doffils of scraped lint: if the hæmorrhage be too profuse, it may be stopped by pledgets of lint dipt in a proper styptic, and the arteries compressed with the fingers till it stops.

These must be covered with a linen bolster, and a large square compress without a plaster, securing the whole with the T bandage, or that with four heads; and if they are ineffectual, the artery must be tied up with a crooked needle and thread. See the article *HÆMORRHAGE*.

After dressing, the patient must be supplied with plenty of ptisan, barley-water, or a strengthening and composing emulsion; his diet should be the same as for people in fevers, or after great wounds. See the articles *FEVER* and *WOUND*.

3. The apparatus altus, or high operation, is performed as follows:—The patient being duly prepared, and laid in a proper situation, a hollow silver catheter, with a flexible leathern tube at the end of it, is to be introduced into the bladder: to the tube must be fitted a large syringe, for the injecting of such warm water, barley-water, or milk,

as the patient can bear. When this is done, the catheter is extracted: then, while an assistant introduces his two fore-fingers into the anus to elevate the stone and bladder, the operator makes an incision in a right line through the skin, fat, and abdominal muscles, immediately above the ossa pubis. The external wound should be three fingers breadth long in children, and four in adults; then introducing the left index, the surgeon feels for the liquor that distends the bladder, and then makes an incision into the bladder immediately above the juncture of the ossa pubis: after which he passes a small knife into the body of the bladder, so as to make a small wound with the point only; through this aperture he passes a crooked or straight knife, armed with a button, whereby he enlarges the wound upwards the breadth of one or two fingers. He then introduces his left index to draw the upper part of the bladder towards the navel, and then enlarges the wound downwards. Immediately after, he introduces the fore-finger of the other hand, and examines the size and situation of the stone, and accordingly he enlarges the wound either upwards or downwards, in order to extract it; and when the stone is extracted, and nothing left, the wound is dressed, and patient treated much in the same manner as in the former case.

4. The fourth method, which is called the lateral operation, was performed by Cheselden thus: every thing being properly prepared, he introduces a catheter, and afterwards makes an incision of a proper length, beginning where they end in the apparatus major, and continuing it downwards between the accelerator urinæ, and erector penis, on the left side of the intestinum rectum; and directing his knife to the posterior part of the catheter, through the inferior and lateral part of the bladder, behind the prostrate gland, and above the feminal vesicles; he then continues it forwards through the sphincter of the bladder, and left side of the prostrate glands into the membranous part of the urethra, even to its bulb, which preserves the rectum better than the lateral method.

Among Cheselden's emendations, Douglas enumerates these: 1. If he finds the patient's pulse low after the operation, he applies blisters to the arms, which effectually raise his spirits. 2. If the wound grows callous, he lays on a piece of blister plaster to erode it, by which new flesh pullulates, and the wound unites. 3. If the wound be putrid, he mixes a little verdigris with some digestive ointment.

Women are less subject to the stone in the bladder than men, and their urinary passages are more short and lax, so that in general, the stone being but small, discharges itself with the urine, and when it happens to increase in the bladder, we have instances of its coming away spontaneously. Douglas proposes to extract a small stone in a woman, by dilating

dilating the urethra with a tent of gentian root, or prepared sponge; but when the stone is large, he approves of the high operation, distending the bladder with warm water, and compressing the urethra by an assistant's finger in the vagina, and then making an incision into the bladder immediately above the os bubis. This, Heister says, is a very proper method, when the stone is very large, and the patient young and healthy; but Morand, when the stone is small, prefers the apparatus major.

Upon the whole, lithotomy appears to be a dangerous and precarious operation, nor can one method alone be depended on; but the surgeon must be determined in the choice, by the particular circumstances of the case.

**LITURGY**, *λειτεργια*, a name given to those set forms of prayer which have been generally used in the Christian church. Of these there are not a few ascribed to the apostles and fathers, but they are almost universally allowed to be spurious.

The liturgy of the church of England was composed in the year 1547, since which time it has undergone several alterations, the last of which was in the year 1661, and of this liturgy Dr. Comber gives the following character:—"No church was ever blessed with so comprehensive, so exact, and so inoffensive a liturgy as ours; which is so judiciously contrived, that the whole may exercise at once their knowledge and devotion; and yet so plain, that the most ignorant may pray with understanding; so full, that nothing is omitted, which ought to be asked in public; and so particular, that it compriseth most things which we would ask in private; and yet so short, as not to tire any that have true devotion. Its doctrine is pure and primitive; its ceremonies so few and innocent, that most of the Christian world agree in them; its method is exact and natural, its language significant and perspicuous, most of the words and phrases being taken out of the Holy Scripture, and the rest are the expressions of the first and purest ages."

And in the opinion of the most impartial and excellent Grotius (who was no member of, nor had any obligation to, this church) "the English liturgy comes so near the primitive pattern, that none of the reformed churches can compare with it." Again, he says, "In the prayers, a scholar can discern close logic, pleasing rhetoric, pure divinity, and the very marrow of the ancient doctrine and discipline; and yet all made so familiar, that the unlearned may safely say, Amen."

**LITUUS**, in Roman antiquity, a short straight rod, only bending a little at one end, used by the augurs. See **AUGUR**.

**LIVER**, *Hepar*, in anatomy, a large and pretty solid mass of a dark red colour, a little inclined to yellow, situated immediately under the arch of the diaphragm, partly in the right hypochondrium, which it fills almost entirely, and partly in the epi-

gastrum, between the appendix ensiformis and spina dorfi, and terminating commonly in the left hypochondrium, into which it sometimes runs a considerable way.

**LIVER-WORT**, *Lichen*, in botany. See the article **LICHEN**.

*Noble LIVER-WORT*. See **HEPATICA**.

**LIVERY** of *Seisin*, in law, signifies delivering the possession of lands, &c. to him who has a right to them.

**LIVERYMEN**, of London, are a number of men chosen from among the freemen of each company. Out of this body the common-council, sheriff, and other superior officers, for the government of the city, are elected, and they alone have the privilege of giving their votes for members of parliament; from which the rest of the citizens are excluded.

**LIVES**, or *Insurance of LIVES*. See the articles **INSURANCE** and **INTEREST**.

**LIVRE**, a French money of account, containing twenty sols.

**LIXIVIOUS**, *Lixivate*, in chemistry, such salts as are extracted from the ashes of burnt vegetables by means of lotion.

**LIXIVIUM**, a ley or water impregnated with the salts of burnt vegetables.

What is left after the evaporation of such a liquor is called a lixivious salt.

Lixiviums are of great use in medicine, bleaching, sugar-works, &c.

**LIZARD**, *Lacerta*, in zoology, a genus of amphibious animals, the body of which is oblong and rounded, the legs four, and the hinder part terminated by a tapering tail.

**LOACH**, the English name of a fish, called by Artdi, the smooth spotted cobitis, with a cylindrical body.

**LOAD**, among miners, denotes a vein of ore. See **MINE**.

It is also used for nine dishes of ore. See the article **DISH**.

**LOADSTONE**, the same with magnet. See **MAGNET**.

**LOAMS**, in natural history, are defined to be earths, composed of dissimilar particles, hard, stiff, dense, and hard and rough to the touch; not easily ductile while moist, readily diffusible in water, and composed of sand and a tough viscid clay. Of these loams, some are whitish, and others brown or yellow.

Some call loam, the most common superficial earth that differs from sand or clay; but the most general appellation of loam is applied to a soft fat earth, partaking of clay, but easy to be wrought.

It is found by experience, that plants of all kinds will grow in it; and wherever it is found, it appears to be a more beneficial soil to plants than any other.

## LOC

**LOBATE**, or **LOBED LEAVES**, are such as are divided to the middle into parts that stand wide from each other, and have their margins convex; and from the number of these they are called bilobate, trilobate, quadrilobate, or quinquelobate; consisting of two, three, four, or five lobes.

**LOBE**, in anatomy, denotes each of the two parts of which the lungs consist. See **LUNGS**.

It is also applied to the divisions of the liver. The word is derived from the Greek *λοβος*, the extremity of a thing.

**LOBELIA**, in botany, a genus of plants, the flower of which is monopetalous and slightly ringent: the fruit is an oval berry with two cells, each containing a single seed.

**LOCAL**, in law, something fixed to the freehold, or tied to a certain place: thus real actions are local, since they must be brought in the country where they lie; and local customs are those peculiar to certain countries and places.

**LOCAL PROBLEM**, among mathematicians, such an one as is capable of an infinite number of different solutions, by reason that the point which is to resolve the problem may be indifferently taken within a certain extent, as suppose any where, within such a line, within such a plane, figure, &c. which is called a geometric locus, and the problem is said to be a local or indetermined one. See **LOCUS**.

**LOCHIA**, in phylic, the purgations of the uterus after child-birth. These consist, generally, for the two first days of a kind of bloody serosity, and gradually become more white, viscous, and less in quantity; which, during the whole time, cannot be determined, some women having more, others less: nor can the duration of the flux be limited to any particular time.

The lochia sometimes flow in too large quantities, either on account of something retained in the uterus, which prevents it from contracting duly; or a too great fluidity or agitation of the blood. If it proceed from a retention of something in the uterus, this must, if possible, be taken away by the hand. But if it proceed from a too great fluidity or agitation of the blood, temperating decoctions of barley, jellies, emulsions, opiates, and astringents, are to be administered.

But when a deficiency in the lochia, or their utter suppression, happens, all possible means should be used to procure this salutary discharge. For this purpose, mild anti-acids, diluters, and aperients, are to be exhibited. But great stress is to be laid on aperient and relaxing topics, clysters, fomentations, plasters, liniments, cupping on the inferior parts, pessaries and suppositories.

Boerhaave advises not to let blood in the above-mentioned disorders, without the utmost necessity.

**LOCK**, a well known instrument for securing doors, chests, &c. and only to be opened by a key. See the article **KEY**.

## LOC

**LOCUS GEOMETRICUS**, in geometry, denotes a line, by any point of which, a local or indeterminate problem is solved.

If a right-line suffice for the construction of the equation, it is called locus ad rectam; if a circle, locus ad circulum; and these were called plain loci: if a parabola, hyperbola, locus ad parabolam, hyperbolam, &c. And those were called solid loci.

Wolffius and the moderns more commodiously divide loci into orders, according to the number of dimensions to which the indeterminate quantities rise.

When in an equation there are two indetermined quantities  $x$  and  $y$ , then for each particular value of  $x$  there may be as many values of  $y$  as it has dimensions in that equation. So that if  $AP$ , a part of the indefinite line  $AE$ , represent  $x$ , and the perpendiculars  $PM$  (plate LXVI. fig. 3.) represent the corresponding values of  $y$ , then there will be as many points  $M$ , the extremities of these perpendiculars or ordinates, as there are dimensions of  $y$  in the equation. And the values of  $PM$  will be the roots of the equation arising by substituting for  $x$  its particular value  $AP$  in any case.

From whence it appears, how, when an equation is given, you may determine as many of the points  $M$  as you please, and draw the line that shall pass through all these points; which is called the locus of the equation.

When any equation involving two unknown quantities,  $x$  and  $y$ , is proposed, then substituting for  $x$  any particular value  $AP$ , if the equation that arises has all its roots positive, the points  $M$  will lie on one side of  $AE$ ; but if any of them are found negative, then these are to be set off on the other side of  $AE$  towards  $m$ .

If for  $x$ , which is supposed undetermined, you substitute a negative quantity, as  $A\bar{p}$ , then you will find the points  $M, m$ , are taken in, that it may shew all the values of  $y$  corresponding to all the possible values of  $x$ .

If, in any case, one of the values of  $y$  vanish, then the point  $M$  coincides with  $P$ , and the locus meets with  $AE$  in that point.

If one of the values of  $y$  becomes infinite, then it shews that the curve has an infinite arch: and in that case the line  $PM$  becomes an asymptote to the curve, or touches it at an infinite distance, if  $AP$  is itself finite.

If, when  $x$  is supposed infinitely great, a value of  $y$  vanish, then the curve approaches to  $AE$  produced as an asymptote. If any values of  $y$  become impossible, then so many points  $M$  vanish.

From what has been said it appears, that when an equation is proposed involving two undetermined quantities,  $x$  and  $y$ , there may be as many intersections of the curve, that is the locus of the equation, and of the line  $PM$ , as there are dimensions of  $y$  in the equation; and as many intersections of the curve and

# LOG

and the line A E as there are dimensions of  $x$  in the equation.

**LOCUST**, *Locusta*, a genus of insects, comprehending the locust, simply so called, the several species of other locusts and grasshoppers, with the crickets of the house and field.

**Water-LOCUST**, *Locusta Aquatica*, the name given by authors to a species of water insect, somewhat resembling the locust kind in shape. It is about three inches long, its tail an inch and a quarter, and its legs are of different lengths; the anterior pair being shortest of all. Its body is slender, and its fore legs are always carried straight forward, so as to reach beyond the head in the form of antennæ. These, as well as the other legs, end each in two claws. The eyes are small and not very prominent, and the upper wings are crustaceous, the under ones membranaceous, thin, and transparent. The middle joint of the leg is such, that the creature can only move them upwards, not downwards; and there runs an acute tongue or proboscis under the belly, as is the case of the water scorpion and notonecta. *Ray's Hist. Insects.*

**LOCUST-TREE**, in botany. See the articles **HYMENÆA** and **ROBINIA**.

**LOCUSTÆ**, in botany, the tender extremities of the branches of trees, such as, it is supposed, St. John Baptist fed on in the wilderness.

**LODGMENT**, in military affairs, is a work raised with earth, gabions, fascines, wool-packs, or mantelets, to cover the besiegers from the enemy's fire, and to prevent their losing a place which they have gained, and are resolved, if possible, to keep. For this purpose, when a lodgment is to be made on the glacis, covert-way, or in a breach, there must be great provision made of fascines, sand-bags, &c. in the trenches; and during the action, the pioneers with fascines, sand-bags, &c. should be making the lodgment, in order to form a covering in as advantageous a manner as possible from the opposite bastion, or the place most to be feared.

**LOEFLINGIA**, in botany, a genus of plants whose flower consists of an upright cup cut into five segments, with five small petals: the stamina are composed of three filaments, topped with double roundish antheræ: the fruit is a three-cornered ovate capsule, with one cell, containing a number of ovate-oblong seeds.

**LOESLIA**, in botany, a genus of plants whose flower is monopelous and unequal, cut at the limb into five parts: the fruit is an ovate trilocular capsule, containing a number of angulated seeds.

**LOG**, in the marine, a machine used to measure the ship's way through the sea.

It is composed of three parts, viz. the reel, the line, and a little board formed like the quadrant of a circle, and nearly resembling the shape of those quadrants employed to take the altitude of a tree,

# LOG

steeple, or other object. The term Log, however, is more particularly confined to this last.

This piece of board is generally from five to six inches in the radius, and a quarter of an inch in depth: and round the arching edge of it, is nailed a thin plate of lead, of sufficient weight to make the log swim perpendicularly in the water, and so, as that nearly two thirds of it may be immersed under the surface. In the middle of the arch, about a quarter of an inch within the edge, is bored a small hole, and another within the angular point; thro' this last is inserted the end of a piece of line, which being knotted on the other side, is drawn tight back to the hole: to the other end of this small cord, which is about two feet long, is fastened a pin, which is thrust into the other hole: the log being then suspended horizontally, the line is fastened to the middle of this small string, so that the pin can occasionally be taken out, and will easily come out of itself when it meets with any resistance.

The log line, whose other end is tied to one of the spokes or shafts of the reel, is generally from four to six hundred feet in length, and is divided into equal spaces, which are marked with one, two, three, four knots, &c. the greatest number being next the reel, and having often single knots between them to determine the half; these large spaces answer to so many miles, and the intermediate ones to half miles, and begin from a red rag which is placed at the distance of ten, twelve, or fifteen fathoms from the log, in proportion to the height of the ship's stern.

The distance of the knots from each other must always be in proportion to the half-minute glass, which is turned at the time of throwing the log into the sea, as the glass may run slower or faster than the time it is calculated for, and must therefore be often tried by a pendulum, the vibrations of which determine how many seconds the glass runs.

If the glass runs thirty seconds, then must the distance of the knots from each other be 50 feet, if it runs more or less, they ought to be corrected in proportion, for,

As thirty seconds

Is to fifty feet,

So is the number of seconds the glass runs

To the length between the knots.

But as the line may often be contracted or lengthened by the moisture or heat of the weather, it must be frequently measured and corrected: the glass must also be proved by the pendulum.

Heaving the log is thus performed:

The log-reel, which turns upon an axis or wooden pin about two feet long, and about which the line is wound, is held by one man, and another holds the half-minute glass, while the mate of the watch fixes the little pin in the log, and throws it over the stern; and as the ship sails, the log swimming

# LOG

ming perpendicular naturally feels a resistance, to prevent which, the mate draws the line quick off the reel, so that it makes a straight line in the water, and the log remains nearly in the same spot where it first alighted in the water. The space of line between the log and the red rag, as mentioned above, is to let the log be far enough a-stern to be out of the ship's eddy or wake, and when this red rag goes over the stern, the glass is turned; and when the glass runs out, the man who held it calls *stop*; the log-line is then stopped, and the log meeting with great resistance, the pin draws out, after which it is easily drawn aboard; and the number of knots and fathoms reckoned from the red rag to the place where the line was stopped, determines the ship's rate of going for an hour: if the wind should freshen or abate in the intervals, so as to make the ship go faster or slower than at the time of heaving the log, the officer generally allows for it at the end of the watch. In ships of war and India-men, the log is heaved once an hour; and in common merchant-men once in two hours, or twice in the watch.

**LOG-BOARD**, a sort of table divided into several columns, containing the hours of the day and night, the courses the ship has run; the winds, and all the material occurrences that happen in the 24 hours, or from noon to noon, together with the latitude by observation. From this table the several officers of the ship copy the materials, and transcribe them, with what additions they can recollect or may think necessary to remark in their journals after their own manner.

**LOG-BOOK**, a book into which the above articles are daily copied, together with every thing material that happens to the ship, or is observed either at sea or in a harbour. The divisions or watches of it, consisting of four hours each, are signed by the lieutenant or commanding officer of the watch in a ship of war or East-India-man. See the articles **JOURNAL** and **WATCH**.

**LOG-WOOD**, or Campeachy-wood, is the wood of a low prickly tree, which grows plentifully about Campeachy, or the bay of Honduras. See **CAMPEACHY-WOOD**.

Log-wood gives out its colour both to watery and spirituous menstrea, but not readily to either: it requires to be rasped and ground into fine powder, and boiled in several fresh parcels of the liquors. Rectified spirit extracts the colour more easily, and from a larger proportion of the wood than water does.

The tinctures both in water and in spirit are of a fine red, with an admixture, particularly in the watery one, of a violet or purple. Volatile alkaline salts, or spirits, incline the colour more to purple: the vegetable and nitrous acids render it pale; the vitriolic and marine acids deepen it.

# LOG

The watery decoction, wrote with on paper, loses its redness in a few days, and becomes wholly violet. This colour communicates also to woollen cloth previously prepared by boiling with a solution of alum and tartar: the dye is beautiful, but very perishable. It is often used by the dyers, as an ingredient in compound colours, for procuring certain shades which are not easily hit by other materials.

With chalybeate solutions, it strikes a black. Hence it is employed in conjunction with those liquors for staining wood black for picture frames, &c. and with the addition of galls, for dyeing cloth and hats black. The black dyes, in which this wood is an ingredient, have a particular lustre and softness, far beyond those made with galls and vitriol alone: the beauty, however, which it here imparts, is not permanent, any more than its own natural violet dye.

On the same principle, it improves also the lustre and blackness of writing ink. Ink made with vitriol and galls, does not attain to its full blackness till after it has lain some time upon the paper: a due addition of log-wood renders it of a deep black as it flows from the pen, especially when vinegar or white-wine is used for the menstruum.

**LOGARITHMIC Curve**, a curve which explains the nature and properties of logarithms, and is delineated in the following manner:

Upon the line *AG* (plate LXVI. *fig. 4.*) infinitely extended each way, let there be taken *AB*, *BC*, *CD*, *DE*, *EF*, &c. towards the right-hand; also *AO*, *OP*, &c. towards the left, all equal among themselves; and from the several points *P*, *O*, *A*, *B*, *C*, *D*, *E*, *F*, &c. let there be drawn the lines *RP*, *OQ*, *AH*, *BI*, *CK*, *DL*, *EM*, *FN*, &c. equal in length to the several lines, in the geometrical scale of proportional lines, infinite in number; these therefore will represent so many terms in the progression of proportionals, of which the line *AH* represents unity. Now if the extremities *R*, *Q*, *H*, *I*, *K*, *L*, *M*, *N*, &c. of the geometrical scale of mean proportionals be connected together by right-lines, the figure *PRNF* will be a polygon, consisting of more or fewer sides, according as the terms in the scales of mean proportionals are more or fewer in number.

If the distances *AB*, *BC*, *DE*, *EF*, &c. are bisected in the points *b*, *c*, *d*, *e*, *f*, &c. and from these points be drawn lines, as *bi*, *ck*, *dl*, *em*, *fn*, &c. perpendicular to *AG*, which will be so many proportionals between *AH*, *BI*, *CK*, *DL*, *EM*, *FN*, &c. there will arise a new scale for a series of proportionals between *AH*, *BI*, *CK*, *DL*, *EM*, *FN*, &c. double in number to those of the former scale. And if the extremities *H*, *i*, *I*, *k*, *K*, *l*, *L*, &c. be connected together by right-lines, we shall have a new polygon, consisting of a greater

greater number of sides; but each side less in magnitude.

After the same manner, if the distance between every two terms be continually bisected, and to each of the points so found, there be applied a series of mean proportionals, the number of terms in this new scale, as also the sides of the polygon, will by this means become infinite; and each side of the polygon will be less than any given right-line, and consequently the polygon will be changed into a curve-lined figure; since every curvilinear figure may be considered as a polygon of an infinite number of sides. The curve thus described is called the logarithmic curve, in which, if the right-lines A H, B I, &c. which stand at right-angles to the axis A G, represent so many terms in a series of numbers in geometrical progression, the portions of the axis A B, B G, &c. between the place of unity and any given term, will shew the place or order that each number in the scale of geometrical proportions obtains from the place of unity in the same series.

The distance therefore between any two numbers, in this continued scale of geometrical proportionals, is the logarithm of the ratio of these two numbers the one to the other. See the article LOGARITHMS.

**LOGARITHMIC Spiral.** If the quadrant of a circle A N B (plate LXVI. fig. 5.) be divided into any number of equal parts, in the points N,  $n$ ,  $n$ , &c. and from the radii C N, C  $n$ , C  $n$ , &c. be cut off C M, C  $m$ , C  $m$ , &c. continual proportionals, the points M,  $m$ ,  $m$ ,  $m$ , &c. will be in the logarithmic spiral. And there may be imagined an infinite number of different curves of this kind.

**LOGARITHMS**, a set of artificial numbers, whereby the common operations in multiplication and division are performed by addition and subtraction; raising powers and extracting roots, are by the help of these numbers easily performed by multiplication and division.

The word is formed from the Greek,  $\lambda\omicron\gamma\omicron\varsigma$ , ratio, and  $\alpha\rho\iota\theta\mu\omicron\varsigma$ , number.

Logarithms, justly esteemed one of the greatest and most useful discoveries that the last century has produced, were first invented by John Neper, baron of Marchifston, in Scotland, and by him first published at Edinburgh in the year 1614; and soon after, by himself and Mr. Briggs, (then Savilian professor of geometry in the university of Oxford) reduced into a better form, and published in London in the year 1624, in the same form and manner as they are used at this day.

Logarithms may be considered as, and are usually defined to be, a series or rank of numbers in an arithmetical progression, fitted or adapted to the exponents of a series of numbers in a geometrical progression.

If between 1 and  $x$  be inserted a mean proportional, which is  $\sqrt{x}$  or  $x^{\frac{1}{2}}$ , its index  $\frac{1}{2}$  shews that its distance from unity will be but one half of the distance of  $x$  from unity. In like manner, if between  $x$  and  $x^2$  we insert a mean proportional, its index will be 1 and  $\frac{1}{2}$  or  $\frac{3}{2}$ , inasmuch as its distance from unity is once and a half the distance of  $x$  from the same place of unity.

Again, if between 1 and  $x$  be inserted two mean proportionals, the first of these will be the cube-root of  $x$  or  $\sqrt[3]{x}$ , and its index will be  $\frac{1}{3}$ , inasmuch as its distance from the units place is but  $\frac{1}{3}$  of the distance of  $x$ , from the same place of unity; and consequently  $\sqrt[3]{x}$  is expressed by  $x^{\frac{1}{3}}$ , whence it follows, that the index of unity is 0, inasmuch as unity cannot be removed at any distance from itself.

And the same series of geometrical proportionals may be continued on the contrary side of unity, or towards the left hand, and which therefore will decrease in the same manner, or in the same ratio, as the terms placed on the right hand increase.

For the terms  $\frac{1}{x^3}$ ,  $\frac{1}{x^2}$ ,  $\frac{1}{x}$ ,  $\frac{1}{x^2}$ ,  $\frac{1}{x^3}$ , 1,  $x$ ,  $x^2$ ,  $x^3$ ,  $x^4$ ,  $x^5$ , &c. are in the same geometrical progression continued, and have all the same common ratio; wherefore, inasmuch as the distance of  $x$  from unity towards the right hand is positive, or  $+1$ , the distance of  $\frac{1}{x}$  from unity towards the left hand, which is equal to the former, is negative or  $-1$ , which is therefore the index of  $\frac{1}{x}$ , and consequently for  $\frac{1}{x}$  may be written  $x^{-1}$ .

Again, inasmuch as  $x^2$  is on the right side of unity, and positive, and its index  $+2$ , the index of  $\frac{1}{x^2}$ , which is as far distant from unity on the contrary side, or towards the left hand, will be negative, and  $-2$ , and consequently  $\frac{1}{x^2}$  is the same with  $x^{-2}$ : In like manner  $x^{-3}$  is the same with  $\frac{1}{x^3}$ , and  $x^{-4}$  the same with  $\frac{1}{x^4}$ ; whence it comes to

pass that the negative indices shew that the terms to which they belong, are as far distant from unity toward the left hand, as the term whose indices are the same and positive, are removed from unity on the contrary side, or towards the right hand.

Again, as between 1 and  $x$ , in the series increasing from or on the right hand of unity, may be inserted a mean proportional, as  $\sqrt{x}$ , and between this mean proportional and unity be inserted another mean proportional, as  $\sqrt[4]{x}$ , and between the last mean proportional and unity be inserted another mean

## LOG

If logarithms are to be made only to seven places of figures, which are sufficient for common use, twenty-five successive extractions will do for that purpose; that is, we need only extract the 33554432 (or 2 raised to the 25<sup>th</sup> power) root of 10; because in that root there will be found seven cyphers before the first significant figure after the unit; and in the course of these extractions, the denominators of the fractions expounding those roots which are nearest

Logarithms therefore may be of as many sorts as  
you

you can assume different indices of the power of that number whose logarithm is required.

But since fluxions and the higher geometry have been so well understood, mathematicians have directed their views towards facilitating those laborious and operose calculations formerly made use of for constructing tables of logarithms, by help of converging series, and other means, whereby the logarithms of any proposed numbers may now be obtained with very little trouble: an example of this kind may be seen in Mac Laurin's Fluxions, p. 678, vol. ii. where that celebrated mathematician shews that, the logarithm of  $m$  being given, the logarithm of  $m+2$  —  $\log. m$  is equal to  $\frac{2z}{2m \times z}$

multiplied by the series  $1 - \frac{z}{12} \times \frac{1}{m+z} - \frac{1}{m} + \frac{z^3}{360}$

$\times \frac{1}{m+z} - \frac{1}{m^3} - \frac{z^5}{1260} \times \frac{1}{m+z} - \frac{1}{m^5} + \&c.$  This series converges so very swift, that two or three terms are sufficient in almost any case whatsoever.

The indices, or characteristics of logarithms, correspond to the denominative part of the natural numbers, as the other member of the logarithm does to the denominative part of the number: that is, the index shews the denomination, or place of the last (or left hand) figure of the number, and consequently of all the rest. — Thus 0, affixed to a logarithm, denotes the last figure of the number, to which the logarithm answers, to be nothing distant from (i. e. in) the place of units. The index 1 shews the last figure of its number to distant 1 place from the place of units, i. e. to be in the place of tens, and consequently the number itself to be either 10, or some number between that and 100, and so of the other indices. Hence all numbers, which have the same denomination, but not the same numerative parts, are all numbers from 1 to 10; from 10 to 1000; &c. and will have logarithms whose indices are the same, but the other members different. Again, all numbers, which have the same numerative, but not the same denominative part, will have different indices, but the rest of the logarithms the same. If a number be purely decimal, to its logarithm is affixed a negative index, shewing the distance of its first real figure, from the place of units. Thus the logarithm of the decimal .256 is 1,43824; of the decimal .0256 is 2,30824, &c.

To find the logarithm for a number greater than any in the common tables, but less than 10000000. — Cut off four figures on the left hand of the given number, and seek the logarithm in the table; add as many units to the index, as there are figures remaining on the right; subtract the logarithm found, from the next following it, in the table; then, as the difference of numbers in the canon is to the ta-

bular difference of the logarithms answering to them, so are the remaining figures of the given number to the logarithmic difference; which, if it be added to the logarithm before found, the sum will be the logarithm required. Suppose the logarithm of the number 92375 were required. Cut off the four figures 9237, and to the characteristic of the logarithm corresponding to them, add an unit; then,

From the logarith. of the numb. 9238 = 3,9655780  
Subtract logarith. numb. — 9237 = 3,9655309  
Remains tabular difference — — — 471

10 — 471 — 5  
5) 2 — — 1

235

Now to the logarithm — — — — 4,9655309  
Add the difference found — — — — 235  
The sum is the logarithm required — 4,9655544

To find the logarithm of a proper fraction. — Subtract the logarithm of the numerator from that of the denominator, and to the remainder prefix the sign of subtraction. — Thus, suppose it were required to find the logarithm of  $\frac{3}{7}$ ,

Logarithm of 7 = 0,8450980

Logarithm of 3 = 0,4771213

Logarithm of  $\frac{3}{7}$  = 0,3679767

To find the number corresponding to a logarithm greater than any in the table. — First, from the given logarithm, subtract the logarithm of 10, or 100, or 1000, or 10000, till you have a logarithm that will come within the compass of the table; find the number corresponding to this, and multiply it by 10, or 100, or 1000, or 10000, the product is the number required. Suppose, for instance, the number corresponding to the logarithm 7,589982 be required; subtract the logarithm of the number 10000, which is 4,0000000, from 7,589982; the remainder is 3,589982, the number corresponding to which is 5741,1, which, multiplied by 10000, gives 57411000, the number required.

To find the number corresponding to a negative logarithm. — To the given negative logarithm, add the last logarithm of the table, or that of the number 10000, i. e. subtract the first from the second, and find the number corresponding to the remainder; this will be the numerator of the fraction, whose denominator will be 10000. Suppose it be required to find the fraction corresponding to the negative logarithm 0,3679767, subtract this from the remainder 4,0000000

remainder is 3,6320233, the number corresponding to which is 4285 $\frac{71}{100}$ ; the fraction sought therefore is  $\frac{4285\frac{71}{100}}{10000}$ . — The reason of the rule is, that as a fraction is the quotient, arising from the division of the numerator by the denominator, unity will be to the fraction, as the denominator to the numerator; but as unity is to the fraction correspond-

ing

ing to the given negative logarithm, so is 10000 to the number corresponding to the remainder: therefore if 10000 be taken for the denominator, the number will be the numerator of the fraction required.

To find a fourth proportional to three given numbers, add the logarithm of the second to that of the third, and from the sum subtract the logarithm of the first; the remainder is the logarithm of the fourth required. Let the given numbers be 4, 68, and 3.

Logarithm 68 = 1,8325089

Logarithm 3 = 0,4771213

Sum — — = 2,3096302

Logarithm 4 = 0,6020600

Logarithm required 1,7075732

The number in the tables corresponding to which is 51.

**LOGIC**, *λογική*, the art of thinking and reasoning justly; or, it may be defined, the science or history of the human mind, inasmuch as it traces the progress of our knowledge from our first and most simple ideas through all their different combinations, conceptions, and all those numerous deduction that result from variously comparing them one with another. See the articles **IDEA** and **KNOWLEDGE**.

The precise business of logic, therefore, is to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge. It lays open those errors and mistakes we are apt, through inattention, to run into; and teaches how to distinguish between truth, and what only carries the appearance of it. By this means, we grow acquainted with the nature and force of the understanding; see what things lie within its reach; where we may attain certainty and demonstration; and when we must be contented with probability.

These considerations sufficiently evince the usefulness of this science, which is divided into four parts, according to the number of the operations of the mind in its search after knowledge, viz. perception, judgment, reasoning, and method. See the articles **PERCEPTION**, &c.

This valuable art of ranging our ideas, connecting them closely together, and consequently of facilitating the transition from one to another, supplies us with a means of rendering all men's abilities nearly equal. In fact, all our knowledge is reducible to primitive sensations, which is nearly alike in all men. The art of combining and connecting our direct ideas, only gives them a more or less exact arrangement and denomination; whence they become more or less sensible to others. A man, who readily combines his ideas, differs but little from him who combines them slowly; as he who

judges of a picture at sight, differs but little from him who requires to be made sensible of all its parts; both, at the first glance, have the same sensations, though they sink not so deep in the second, who therefore dwells longer upon each, to render them strong and distinct; and by this means, the reflex ideas of the first observer become as easy to the second as direct ones. And hence, perhaps, there is scarce an art or science that may not, by means of a well adapted logic, be taught to a slow understanding; because there are few arts or sciences, whose precepts or rules may not be reduced to simple notions, and disposed in so connected an order, that the chain need never be broken. As the mind is more or less slow in its operations, it requires more or less of this connected order. The advantage of a genius is that of having less occasion for it; or rather, of being able to form it quick, and almost imperceptibly. See **DEMONSTRATION**.

**LOGISTIC CURVE**, the same with that otherwise called logarithmic. See the article **LOGARITHMIC**.

**LOGISTIC SPIRAL**. See **LOGARITHMIC** and **SPIRAL**.

**LOGISTICA NUMERALIS**, the same with algorithm. See **ALGORITHM**.

**LOGISTICAL ARITHMETIC**, the doctrine of sexagesimal fractions. See the article **SEXAGESIMAL**.

**LOHOCH**, or **LOCH**, in pharmacy, a composition of a middle consistence between a soft electuary and a syrup, principally used in disorders of the lungs. See **LINCTUS**.

**LOINS**, *Lumbi*, in anatomy, the two lateral parts of the umbilical region of the abdomen. See the article **ABDOMEN**.

**LODIUM**, darnel, in botany, a genus of plants, the corolla whereof consists of two valves; the lower is narrow, lanceolated, convoluted, acuminate, and of the length of the cup; the other is short, linear, obtuse, and hollowed upwards: there is no pericarpium; the corolla incloses the seed, which is single, oblong, compressed, convex on one side, and plane and sulcated in the middle on the other.

The seed of this plant is reckoned attenuant, abstergent, drying, and heating.

**LONCHITIS**, spleenwort, in botany, a genus of cryptogamous plants of the fern kind, the fructifications of which are disposed in small lines, separately under the sinuses of the leaves, and arranged into lunulated series. It grows wild in divers parts of England.

The leaves are of use for healing wounds, and in preventing inflammations of them; they are also used against the spleen; the root is aperient and diuretic.

**LONDON-PRIDE**, the English name for a species of saxifrage. See the article **SAXIFRAGE**.

**LONGÆVITY**, from *longus*, long, and *vita*, life, length of life.

We have several instances of longævity, as Parr, who lived one hundred and thirty-two years and nine months; Henry Jenkins, of Yorkshire, who lived one hundred and sixty-nine; the countess of Desmond, and Mr. Ecclestone, both of Ireland, each of whom exceeded one hundred and forty years.

**LONG-BOAT**, in the marine, the largest and strongest boat in the ship.

The use of the long-boat is to carry great bins, such as water, provisions, anchors, and cables, and often part of the cargo: she is occasionally equipped with a mast, sails, and rigging, sometimes armed with swivels, musketoons, and carabines, and can be decked as necessity requires.

**LONGIMETRY**, the art of measuring lengths, accessible and inaccessible.

**LONGISSIMUS DORSI**, in anatomy, a very complex, long, and narrow muscle, situated between the spinal apophyses, and the sacro-lumbaris, from which it is divided by a fatty or cellular line; but, at the lower part, they are confounded together. It covers the semispinalis, or transverso-spinalis dorsi, and semispinalis lumborum. Its upper part lies between the sacro-lumbaris and transversalis colli. This muscle and the sacro-lumbaris are common to the back and loins. The longissimus dorsi is an assistant to the sacro-lumbaris, especially its vertebral portion, which it helps very powerfully both by the multiplicity and insertions of its fibres, in sustaining the vertebræ of the back and loins, while extended, whether in sitting or standing, and in preventing their sinking under the weight of the body, or any additional burden. It assists in performing, or counterbalancing all the motions and inflections which these vertebræ, especially those of the loins, are capable of in all postures of the body. And in this, it also bears some resemblance to the inferior or vertebral portion of the splenius: and these two muscles on each side, and the sacro-lumbaris, are of the number of those called vertebræ obliquæ divergentes. *Winslow's Anat.*

**LONGITUDE of the Earth**, denotes its extent from west to east, according to the direction of the equator.

**LONGITUDE of a Star**, &c. in astronomy, an arch of the ecliptic, counted from the beginning of Aries, to the place where a star's circle of longitude cuts the ecliptic.

**LONGITUDE of a Place**, in geography, its distance from some first meridian, or an arch of the equator intercepted between the meridian of the place and the first meridian.

**LONGITUDE**, in navigation, the distance of a ship or place, east or west, from one another, counted in degrees of the equator. If this distance be counted in leagues, miles, &c. or in degrees of the

meridian, and not in those proper to the parallel of latitude, it is usually called departure.

Since the difference of longitude between any two places is equal to the arch of the equator intercepted between the two meridians passing through the two places; which is analogous to the quantity of time that the sun requires to move from the meridian of one place to that of another; or, in the language of the Copernicans, that is elapsed between the application of the meridian of one of the places to the sun and the meridian of the other; for, since the sun finishes his diurnal revolution in the space of 24 hours, or, which is the same thing, since the revolution of the earth about her axis is performed in the same time, it follows, that in every hour there passes over the meridian one-twenty-fourth part of 360 degrees, or of the whole circumference of the equator, equal to fifteen degrees; in two hours, one-twelfth part, or thirty degrees; and, in any greater or lesser part of time, a proportional greater or lesser part of the equator; whence it follows, that if the difference of longitude, or arch of the equator intercepted between the meridians passing through any two places, be known, the difference of the times of the day in those two places is known also; and, consequently, the hour in one place being known, the hour in the other place is known also; and, on the contrary, if the difference between the times at any two places be known, the difference of longitude between those two places is known also, by reducing the difference of the times into degrees and minutes, allowing fifteen degrees to an hour, &c.

Hence it is, that if two or more places lie under the same meridian, the hour in one will be the same with the hour in the other; and, on the contrary, if in two or more places the hour be the same, those places lie under the same meridian.

And, because the sun in all places constantly rises in the east, he must necessarily apply himself to the meridian of the easternmost place first, and, consequently, in that place that lies to the easternmost, the noon happens soonest; and the hour of the day or distance of the sun from the meridian at any other time must be greatest.

Whence it appears, that if, by any contrivance whatsoever, the hour of the day at the same point of absolute time in two different places can be obtained, the difference of longitude between those places is also known; and by comparing the times together, it is easy to pronounce which place of the two lies to the eastward or westward of the other.

Wherefore if two or more persons can view the same appearance at two or more places, and pronounce the time at each place when such appearance was visible; or if the time when any notable appearance shall happen at any place be predicted, and the time when that appearance was visible at any other place was determined; these times being compared together, will give the difference of meri-

ridian,

ridians, or difference of longitude between the two places.

Now since an eclipse of the moon proceeds from nothing else but an interception of the earth between her and the sun, by which means she is prevented from reflecting the light she receives from the sun, the moment that any part of her body begins to be deprived of the solar rays, it is visible to all those people who can see her at the same time; whence if two or more different people, at two or more different places, observe the times when it first began or ended, or note the time when any number of digits was eclipsed, or when the shadow begins to cover or quit any remarkable spot, the difference of those times, if there be any, when compared together, will give the difference of longitude between the places of observation.

The longitudes of places may also be determined from the observations of solar eclipses; but these being incumbered with the considerations of parallaxes, are not near so proper as those of the moon are; and each of these happening but rarely, another excellent expedient has been thought of, and that is the eclipses of Jupiter's satellites.

Jupiter has been found to have four satellites or moons constantly attending him, always observing the same laws in moving round about him. See the article JUPITER.

Now as neither Jupiter nor any of his attendants have any native light of their own, but shine with a borrowed light from the sun, it happens that each of these, in every revolution about Jupiter, suffers two eclipses, one at their entrance into the shadow, the other at the entrance of their passage behind his body; whence in each revolution of the satellite there are four remarkable appearances, by the observation of any one of which the business may be done, viz. one at the entrance into the shadow, and one at the emersion out of it; one at the entrance behind the body, and another at the coming out; but the latter of these, viz. the ingress and egress of the satellite, into and from under the body, is not so much regarded by astronomers as the immersion into and out of the shadow, because in the former, the difficulty of pronouncing the exact time is very great, it requiring, in each observer, eyes equally good and strong, and telescopes equally large; but the observation of the former of these, viz. the immersion into, and emersion out of the shadow, is easy and practicable, because the quick motions of the satellites plunge them so quick into the shadow of Jupiter, that is no difficult matter to pronounce, by any telescope, by which they may be seen, the exact time of their immersion and emersion, as any one may soon be satisfied, if he will but try the experiment.

Now, inasmuch as each of these happens at the same moment of absolute time, if two or more

persons in different places note the time of observation, these, when compared together, will give the difference of longitude between the two places of observation. And, when we consider the great number of these eclipses that happen every year, there being more visible in one year than there are days in it, and, consequently, but few nights when Jupiter may be seen, and which is near eleven months of the year, but that an eclipse of one or other happens, and sometimes two or three in a night; the easiness with which they may be made, there requiring only a telescope of eight or ten feet in length, which may be almost managed with the hand; and the little likelihood there is of missing the times of ingress or egress, they being in a manner momentaneous; and lastly, the great exactness to which they would give the difference of longitude, it being certainly as exact as the latitude can at present be taken; it is much to be wondered at, that the more skilful part of our seamen have so long neglected them, and especially in the several ports into which they sail.

Besides these, there is another method equally useful, expeditious, and certain; and that is, the appulses of the moon to certain fixed stars, and their occultations by the interposition of her body; for, the moon finishing her revolution in the space of twenty-seven days, seven hours, forty-three minutes, there are but few clear nights, when the moon does not pass over, or so near to some fixed star, that her distance from it, or the time of her visible conjunction with it, may be easily observed by the telescope and micrometer only; and these when compared together or with the visible time computed to the meridian of some place when a good theory of the moon shall be obtained, will shew the difference of longitude of those places.

The lunar theory is already brought to very great perfection, and the Nautical Ephemerides, now preparing by that able mathematician Mr. George Witchel, will, it is hoped, render the method of finding the longitude at sea very practicable; especially as the ingenious Mr. Maskeline has already favoured the world with a treatise called the British Mariner's Guide, wherein he has fully explained the method of finding the longitude from observations made on the appulses of the moon to the fixed stars.

Mr. Flamsteed has given us the places of near one thousand fixed stars, confirmed by several observations, that lie within the zodiac, each of which will be covered by the moon and the rest of the planets, in one revolution of their node; so that scarce one night can happen but some one or other of them will be eclipsed, or approached so near unto, as to come within the compass of a telescope, in one place of the earth or other: add to these the eclipses of Jupiter's satellites, and it is scarce possible that any clear night can happen, but

but the heavens afford us some agreeable phenomenon or other, by which the longitude of any place may be duly ascertained.

In the Philosophical Transactions, N<sup>o</sup> 1, we have an account of a successful experiment made with two pendulum-watches by major Holmes, in a voyage from the coast of Guinea home-wards. This and some other successful encouraged monsieur Huygens so far, that, after he had improved the structure of these watches, he published an account at large for shewing how and in what manner these watches are to be used in finding the longitude at sea, with directions for adjusting of them and keeping a journal by them; which account the curious reader may see at large in the Philosophical Transactions N<sup>o</sup> 47.

This method has been pursued by the ingenious Mr. John Harrison, who, after many years labour, has at last completed a time-keeper, which has every requisite necessary for finding the longitude at sea; and from several experiments, particularly two voyages to the West-Indies, it was found to keep time so very accurately as not to vary above a minute in the whole voyage: and he has accordingly received 10,000*l.* being half the stipulated reward for this discovery; and will it is presumed, receive the other moiety as soon as his watch shall be found to keep time with the same degree of accuracy, in the frozen zone. The reader will therefore be pleased with finding some account of this ingenious contrivance, which we shall give from a report delivered to the board of longitude, by Mr. William Ludlam, one of the gentlemen to whom Mr. Harrison was referred to make a discovery of the principles of his time piece.

"The defects in common watches, says Mr. Ludlam, which Mr. Harrison proposes to remedy, are the following.

"1. That the main-spring acts not constantly with the same force upon the wheels, and through them upon the balance. 2. That the balance, either urged with an unequal force, or meeting with a different resistance from the air or the oil, or the friction, vibrates through a greater or less arch. 3. That these unequal vibrations are not performed in equal times. 4. That the force of the balance-spring is altered by a change of heat.

"To remedy the first defect, Mr. Harrison has contrived, that his watch shall be moved by a very tender spring, which never unrolls itself more than one eighth part of a turn, and acts upon the balance through one wheel only. But such a spring cannot keep the watch in motion a long time. He has therefore joined another, whose office is to wind up the first spring eight times in every minute, and which is itself wound up but once in a day.

"To remedy the second defect, Mr. Harrison uses a much stronger balance-spring than in a common watch. For if the force of this spring upon

the balance remains the same, whilst the force of the other varies, the errors arising from that variation will be the less, as the fixed force is the greater. But a stronger spring will require either a heavier or a larger balance. A heavier balance would have a greater friction. Mr. Harrison therefore increases the diameter of it. In a common watch it is under an inch, in this of Mr. Harrison's two inches and two tenths.

"Had these remedies been perfect, it would have been unnecessary to consider the defects of the third sort. But the methods already described only lessening the errors, not removing them, Mr. Harrison uses two ways to make the times of the vibrations equal, though the arches may be unequal. One is to place a pin, so that the balance-spring, pressing against it, has its force increased; but increased less when the vibrations are larger; the other to give the palates such a shape, that the wheels press them with less advantage, when the vibrations are larger.

"To remedy the last defect, Mr. Harrison uses a bar compounded of two thin plates of brass and steel, about two inches in length, rivited in several places together, fastened at one end, and having two pins at the other, between which the balance spring passes. If this bar be strait in temperate weather, brass changing its length by heat more than steel, the brass side becomes convex when it is heated; and the steel side when it is cold: and thus the pins lay hold of a different part of the spring in different degrees of heat, and lengthen or shorten it, as the regulator does in a common watch.

"The two first of these improvements, any good workman who should be permitted to view and take to pieces Mr. Harrison's watch, and be acquainted with the tools he uses, and the directions he has given, could, without doubt, exactly imitate. He could also make the palates of the shape proposed; but for the other improvements, Mr. Harrison has given no rules. He says, that he adjusted those parts by repeated trials, and that he knows no other method. This seems to require patience and perseverance; but with these qualifications other workmen need not despair of success equal to Mr. Harrison's. There is no reason to suspect that Mr. Harrison has concealed from us any part of his art.

"If our opinion of the excellence and usefulness of this machine be asked, I must fairly own, that nothing but experience can determine the use of it with certainty; however, I think it my duty, says the above gentleman, to declare to the board the best judgment I can form.

"The first of Mr. Harrison's alterations is, I believe, an improvement, but not very considerable. Probably if the other defects in common watches could be removed, the changes in the force of the main-

main-spring would not occasion such errors as would make them useless at sea.

"The next alteration seems to be of greater importance; I suppose it contributes more to the exactness of the watch, than all the other changes put together; but is attended with some inconvenience. The watch is liable to be disordered, and even stopped by almost any sudden motion, and, when stopped, does not move again of itself. But as it has gone two voyages without any such accident, it may seem that this danger at sea is not considerable.

"The principal on which Mr. Harrison forms the alterations of the third sort is, that the longer vibrations of a balance moved by the same spring, are performed in less time. This is contrary to the received opinion among the philosophers and workmen. But if Mr. Harrison is right, yet whether the method he has proposed will correct the errors, or not, is to me quite uncertain.

"The last alteration beforementioned is ingenious and useful; but that it can be made to answer exactly to the different degrees of heat, seems not probable."

*LONGITUDE of Motion*, according to some philosophers, is the distance which the center of any moving body runs through, as it moves on in a right line. See the article *MOTION*.

*LONGITUDINAL*, in general, denotes something placed lengthwise: thus some of the fibres of the vessels in the human body are placed longitudinally, others transversely, or across.

*LONICERA*, honey-suckle, in botany, a genus of plants, the corolla of which is monopetalous and tubulous, the tube is oblong and gibbous; the limb is divided into five parts, one of which is more deeply cut than the rest, the stamina are five subulated filaments top'd with oblong antheræ; the fruit is a roundish umbilicated berry, having two cells containing roundish compressed seeds. This genus includes the caprifolium, periclymenum, chamæcerasus and xylosteum of Tournefort, and the symphoricarpos of Dillenius.

*LOOF*, in ship-building, that part of a ship where the bow begins, or where the planks of her fore part begin to bend, and round inward as she grows narrower approaching the stem. See *Bow*.

*LOOKING-GLASSES* are nothing but plane mirrors of glass; which being impervious to the light, reflect the images of things placed before them; for the theory of which see the articles *MIRROR* and *REFLECTION*.

For the casting, grinding, and polishing glasses, see the article *GLASS*.

For foliating of looking glasses, see the article *FOLIATING*.

*LOOM*, a frame composed of a variety of parts, used in all the branches of weaving; for a particular description of which, see *WEAVING*.

*LOOMING*, in the sea-language, appearance, as the ship looms large, i. e. appears towering.

*LOOP*, in the iron works, denotes a part of a sow, or block of cast iron, broken or melted off from the rest.

*LOOSE-STRIFE*, in botany. See *LYSIMACHIA*.

*LOPPING*, among gardeners, the cutting off the side branches of trees.

It is very observable that most old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of those who have the management of them, who suffer the tops to grow large before they lop them; as the ash, elm, hornbeam, &c. and persuade themselves, that they may have the more great wood; but in the mean time, do not consider that the cutting off great tops endangers the life of a tree; or, at best wounds it so, that many trees yearly decay more in their bodies than the yearly tops come to; and at the same time that they furnish themselves with more great wood, they do it at the loss of the owner. And, indeed, though the hornbeam and elm will bear great tops, when the body is little more than a shell; yet the ash, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays. Therefore, if once these trees decay much in the middle, they will be worth little but for the fire; so that if you find a timber-tree decay it should be cut down in time that the timber be not lost.

The lopping of young trees, that is, at ten or twelve years old at most, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, spoil many a tree; for which reason they should always be taken off close and smooth, and not parallel to the horizon; and cover the wound with loam and horse-dung mixed, to prevent the wet from entering into the body of the tree.

When trees are at their full growth, there are several signs of their decay; as the withering or dying of many of their top branches; or if the wet enters at any knot; or they are any wise hollow or discoloured; if they make but poor shoots; or if woodpeckers make any hole in them.

This lopping of trees is only to be understood for pollard trees; because nothing is more injurious to the growth of timber-trees, than that of lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and size, growing near each other, to lop or cut off the side branches from one of them, and suffer all the branches to grow upon the other, will in a few years, find the latter to exceed the other in growth every way; and this will not decay near so soon.

All

All sorts of resinous trees, or such as abound with a milky juice, should be lopped very sparingly; for they are subject to decay when often cut. The best season for lopping these trees is soon after Bartholomew-tide; at which time they seldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Dict.*

The generality of the world are against pruning timber trees at all, and, where they naturally grow straight and regular, it is much better let alone. But all common faults in shape may be regulated by this lopping them while young, and it can be attended with no ill consequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and squared in the working for beams and other uses, or to be quartered; for all the defects occasioned by such wounds, are in the superficial parts, and all the four quarters are perfectly found within.

As to the large forest trees, they should not be lopped at all, except in cases of great necessity, and then the large boughs must not be cut, but only the side branches; and even these must be cut off close, that the bark may soon cover the wound, and yet a little slanting, that the water may run off, not lodge upon the cut part.

If there is a necessity of cutting off a large bough, as by its being broken or cankered, let it be cut off slanting at about four feet distance from the body of the tree, and that if possible near some place where there is a young shoot from it, which may receive the sap, and grow up in its place. No stump must be left standing out farther than this, because they are wounded parts which never can heal, and which will always be letting in the water, and will serve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly spoil it. All that grow upright, whether they be large or small branches, must in cutting be taken off slanting, never evenly, for the same reason; those boughs that bear from the head are to be cut with the slope on the lower side, and on any occasion that great wounds are given to a tree, they should be covered with a mixture of clay and horse dung, which will make them heal much sooner than they otherwise would do. *Mortimer's Husbandry.*

LORD, a title of honour given to those who are noble, either by birth or creation; in this sense it amounts to much the same as peer of the realm, or lord of parliament. This title, by the courtesy of England, is also given to all the sons of dukes and marquises, and to the eldest sons of earls: and it is also a title of honour bestowed on those who are honourable by their employments, as lord advocate, lord chamberlain, lord chancellor, &c.

LORICATION, COATING, in chemistry, is the covering a glass or earthen vessel with a coat of

crust of a matter able to resist the heat, to prevent its breaking in the performing an operation that requires violence of fire.

LOTION, *Lotio*, washing, in physic, a sort of medicine compounded of liquid ingredients for beautifying the face, and cleansing it from any deformity which the blood throws out. It also denotes a medicine that holds a medium between a fomentation and a bath.

LOTION, in pharmacy, a preparation of medicines by washing in some liquid, either to clear them of the dregs, or of some salt or corrosive spirit, or to communicate some virtue to them.

LOTUS, bird's-foot, trefoil, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is roundish, bent backward with an oblong concave unguis; the alæ are broad, roundish, and shorter than the vexillum, closing together at the top; the carina is gibbous underneath and shut above. The fruit is a cylindric pod, consisting of two valves, having many transverse partitions, in each of which is placed a roundish seed.

LOVAGE, in botany, the English name for the ligusticum. See LIGUSTICUM.

LOVE-APPLE, the fruit of a species of solanum, a plant cultivated in gardens among us for the singularity of its appearance; the Portuguese eat this fruit either raw or stewed, as do also the Jew-families in England.

LOUIS, or *Knight of St. Louis*, the name of a military order in France, instituted by Louis XIV. in 1693. Their collars are of a flame colour, and pass from left to right; the king is their grand master.

LOUSE, *Pediculus*, in zoology. See the article PEDICULUS.

LOWERING, among distillers, a term used to express the debasing the strength of any spirituous liquor by mixing water with it.

LOXIA, in the Linnæan system of zoology, the name of a genus of birds of the order of the passerines, the distinguishing characters of which are, that the tongue is plain, equal, and whole; the beak large, thick, and short, and crooked and convex both ways.

LOZENGE, LOZANGE, *Rhombus*, in geometry, a quadrilateral figure, consisting of four equal and parallel sides, two of whose opposite angles are acute, and the other two obtuse; the distance between the two obtuse ones being always equal to the length of one side: when the sides are unequal this figure is called a RHOMBOIDES, which see.

Scaliger derives the word from the Latin *laurengia*, as this figure somewhat resembles that of a laurel leaf.

LOZENGE, in heraldry, a rhombus, or figure of equal sides, but unequal angles, resembling a quarry of glass in our old windows, placed erect, pointwise. It is in this figure that all unmarried

gentlewomen and widows bear their coats of arms; because, as some say, it was the figure of the Amazonian shield; or, as others, because it is the ancient figure of the spindle.

LOZENGE, in pharmacy, the same with what is otherwise called troche. See the article TROCHE.

LUCERNE, in botany, &c. a plant frequently cultivated in the manner of clover, and known among authors by the names of the medica and medicago.

It is the alfalfa of the Spaniards, and the lucerne, grand treffle, or fœnum Burgundiacum, as some botanists call it, of the French. It has a perennial root, and an annual stalk, which rises full three feet high in good land, and is garnished at each point with trifoliate leaves, whose lobes are spear-shaped, about an inch and a half long, and half an inch broad, sawed towards the stalks. The flowers grow in spikes, which are from two to near three inches in length, standing upon naked foot-stalks two inches long, rising from the wings of the stalks: they are of the pea-bloom, or butterfly, kind; of a fine purple colour, and are succeeded by compressed moon-shaped pods, which contain several kidney-shaped seeds. It flowers in June, and its seed ripens in September.

There are the following varieties of this species of lucerne, viz. one with violet-coloured flowers; another with yellow flowers; a third with yellow and violet flowers mixed; and a fourth with variegated flowers: but, as Mr. Miller observes, these are only variations of the same plant, arising accidentally from the seed. However, neither the yellow nor the variegated flowered lucerne, is ever so strong as that with purple flowers, nor is it, consequently, so profitable to the husbandman.

Columella calls this the choicest of all fodder, because it will last ten years, and will bear being cut down four, and sometimes six times in a year; it enriches the land on which it grows, fattens the cattle fed with it, and is a remedy for sick cattle. About three quarters of an acre of it is abundantly sufficient to feed three horses during the whole year. Yet, notwithstanding it was so much esteemed by the ancients, and hath been cultivated to great advantage in France and Switzerland for many years, it has not yet found so good a reception in England as it justly deserves; nor is it cultivated here in any considerable quantity, though it will succeed as well in this country as in either of the last mentioned; being extremely hardy, and resisting the severest cold of our climate.

The soil in which this plant is found to succeed best, in this country, is a light, dry, loose, sandy land, which should be well ploughed and dressed, and the roots of all noxious weeds, such as couch-grass, &c. destroyed; otherwise they will overgrow the plants while young, and prevent their progress.

The best time to sow the seed is about the middle of April, when the weather is settled and fair; for if you sow it when the ground is very wet, or in a rainy season, the seeds will burst and come to nothing, as is often the case with several of the leguminous plants; therefore, you should always observe to sow it in a dry season, and if there happens some rain in about a week or ten days after it is sown, the plants will soon appear above-ground.

After having well ploughed and harrowed the land very fine, you should make a drill quite across the ground, almost half an inch deep, into which the seeds should be scattered very thin; then cover them over a quarter of an inch thick, or somewhat more, with the earth: then proceed to make another drill, about a foot and a half from the former, sowing the seeds therein in the same manner as before, and so proceed through the whole spot of ground, allowing the same distance between each row, and scatter the seeds very thin in the drills. In this manner, an acre of land will require about six pounds of seed: for when it is sown thicker, if the seeds grow well, the plants will be so close as to spoil each other in a year or two, the heads of them growing to a considerable size, as will also the roots, provided they have room; for the crown of some will measure eighteen inches diameter; from which near four hundred shoots have been cut at one time, which is an extraordinary increase, and this upon a poor, dry, gravelly soil, which had not been dunged for many years, but the roots were at least ten years old; so that if this crop be well cultivated, it will continue many years, and be equally good as when it was first sown: for the roots generally run down very deep in the ground, provided the soil be dry; and although they should meet a hard gravel a foot below the surface, yet their roots would penetrate it and make their way downward, some of them having been taken up, which were above a yard in length, and had run two feet into a rock of gravel, so hard as not to be loosened without mattocks, and crows of iron, and that with much difficulty.

The reason for directing this seed to be sown in rows is, that the plants may have room to grow; and for the better stirring the ground between them, to destroy the weeds, and encourage the growth of the plants, which may be very easily effected with a Dutch hoe, just after the cutting the crop each time, which will cause the plants to shoot again in a very little time, and be much stronger than in such places where the ground cannot be stirred: but when the plants first come up, the ground between should be hoed with a common hoe; and if in doing this you cut up the plants where they are too thick, it will cause the remaining to be much stronger. This hoeing should be repeated two or three times while the plants are young, according as the weeds are produced, observing always to do it in dry weather,

ther, that the weeds may the better be destroyed; for if be done in moist weater, they will root and grow again.

With this management, the plants will grow to the height of two feet, or more, by the beginning of August, when the flowers will begin to appear, at which time the lucerne should be cut, observing to do it in a dry season, if it is to be made hay, and keep it often turning, that it may soon dry, and be carried off the ground: for if it lie long upon the roots, it will prevent their shooting again. After the crop is taken off, you should stir the ground between the rows with a hoe, to kill the weeds, and loosen the surface, which will cause the plants to shoot out again in a short time, so that by the beginning of September there will be shoots four or five inches high, when you may turn in sheep upon it to feed it down: nor should the shoots be suffered to remain upon the plants, which would decay when the frosty weather comes on, and fall down upon the crown of the roots, and prevent their shooting early the succeeding spring.

The best way therefore is to feed it until November, when it will have done shooting for that season: but it should not be fed with large cattle the first year, because the roots being young, would be in danger of being destroyed, either by their trampling upon them, or their pulling them out of the ground: but sheep will be of service to the roots by dunging the ground, provided they do not eat too close, so as to endanger the crown of the roots.

In the beginning of February, the ground between the rows should be again stirred with the hoe, to encourage them to shoot again: but in doing this you should be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to push. With this management, if the soil be warm, by the middle of March the shoots will be five or six inches high, when, if you are in want of fodder, you may feed it down till a week in April; after which it should be suffered to grow for a crop, which will be fit to cut the beginning of June, when you should observe to get it off the ground as soon as possible, and stir the ground again with the Dutch hoe, which will forward the plants shooting again; so that by the middle, or latter end of July, there will be another crop fit to cut, which must be managed as before; after which it should be fed down again in autumn: and as the rows by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you should turn in larger cattle; but you must always observe not to suffer them to remain after the roots have done shooting, lest they should eat down the crown of the roots below the buds, which would considerably damage, if not destroy them.

In this manner you may continue constantly to have two crops to cut, and two feedings upon this

plant; and in good seasons there may be three crops cut, and two feedings, which will be a great improvement, especially as this plant will grow upon dry barren soils, where grass will come to little, and be of great use in dry summers, when grass is often burnt up: and as it is an early plant in the spring, so it will be of great service when fodder falls short at that season, when it will be fit to feed at least a month before grass or clover; for this plant is often eight inches high by the middle of March, at which time the grass in the same place is scarcely one inch high.

Cold will not injure this plant; for in the very cold winter, 1728-9, some roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, were again planted, and they shot out very vigorously soon after: nay, even while they lay upon the ground, they struck out shoots from the under side of the roots, and had begun to shoot green from the crown of the roots: but wet will altogether destroy the roots; for a little of the seed being sown upon a moist spot of ground for a trial, it came up very well, and flourished exceedingly during the summer season; but in winter, when the great rains fell, the roots began to rot at bottom; and before the spring most of them were destroyed.

The best places to procure the seed from, are Switzerland, and the northern parts of France, which succeeds better with us than that which comes from a more southern climate: but this seed may be saved in England in great plenty; in order to which, a small quantity of the plants should be suffered to grow uncut till the seeds are ripe, when it must be cut, and laid to dry in an open barn, where the air may freely pass through: but the seed must be defended from the wet; for if it be exposed thereto, it will shoot while it remains in the pod, whereby it will be spoiled. When it is quite dry, it must be threshed out, and cleaned from the husk, and preserved in a dry place till the season for sowing it: and this seed saved in England is much preferable to any brought from abroad; the plants produced from it being much stronger than those produced from the French, Helvetian, and Turkey seeds, which are sown at the same time, and on the same soil and situation.

**LUCID INTERVALS**, in lunatics, the times wherein they appear to be in their full senses. See the article **LUNATIC**.

**LUCIDA**, in astronomy, an appellation given to several fixed stars, on account of their superior brightness; as the lucida coronæ, a star of the second magnitude, in the northern crown; the lucidæ hydræ, or cor hydræ; and the lucida lyræ, a star of the first magnitude in that constellation.

**LUCIUS**, the pike, or jack, in ichthyology, a species of eelox, with a depressed rostrum.

The

The pike grows to a considerable size, but usually is found from fourteen inches to two feet in length: it is all over variegated with round yellowish spots. It is a well known and very voracious fish.

**LUES**, among physicians, is, in general, used for a disease of any kind; but, in a more particular sense, is restrained to contagious and pestilential diseases: thus the lues Gallica, or venerea, signifies the venereal disease.

**LUFF**, amongst sailors, the order from the pilot to guide the ship's head nearer to the direction of the wind, or nearer to that part of the horizon from which the wind bloweth.

*She keeps a good LUFF*, i. e. holds her way well, without deviating to the leeward of her course. See the article **LEEWARD**.

**LUFF-TACKLE**, a complication of pulleys, consisting of two blocks, which may be either both of them double, or one of them single. The rope which forms the tackle, and is called the fall, is passed alternately through the blocks, and then has its end fastened to one of them, till it becomes four or five fold: the mechanical power of a luff-tackle is very great, inasmuch that three or four men will draw as much weight with this as seven or eight would with a single rope fastened to the same body. See the article **TACKLE**.

**LUKE**, or *Gospel of St. LUKE*, a canonical book of the New Testament.

Some think it was properly St. Paul's Gospel, and that when that apostle speaks of his Gospel, he means what is called St. Luke's. Irenæus says, that St. Luke digested into writing what St. Paul preached to the gentiles; and Gregory Nazienzen tells us, that St. Luke wrote with the assistance of St. Paul.

"St. Luke, says a modern writer, is pure, copious, and flowing, in his language; and has a wonderful and entertaining variety of select circumstances in his narration of our Saviour's divine actions. He acquaints us with numerous passages of the evangelical history, not related by any other Evangelist; both in his Gospel and Apostolical Acts, he is accurate and neat, clear and flowing, with a natural and easy grace: his style is admirably accommodated to the design of his history; it had a good deal of resemblance to that of his great master St. Paul; and, like him, he had a learned and liberal education. I believe he had been very conversant with the best classics; for many of his words and expressions are exactly parallel to theirs." *Blackwall's Sacred Classics*.

*St. LUKE the Evangelist's Day*, a festival in the Christian church, observed on the eighteenth of October.

**LUMBAGO**, in physic, a violent pain in the

loins, which affects the patient in such a manner that he can scarcely move. It is a scorbutic symptom, and frequently excited by the gout or rheumatism.

**LUMBARIS**, a name given to the arteries and veins which spread over the loins; or an epithet to distinguish those branches of the aorta which carry the blood to the muscles of the loins, to those of the abdomen and other of the circumjacent parts, and also to certain veins which bring back the blood from the loins into the trunk of the vena cava.

**LUMBRICAL**, a name given to four muscles of the fingers, and to as many of the toes. They are in each called the flexors of the first phalanx: those of the fingers arise deep and tendinous, and are inserted into the first phalanges on the side next the thumb: those of the toes have their origin from the tendon of the musculus perforans, and from the interior part of the calcaneum: their termination is at the first phalanx of the several toes.

**LUNA**, in astronomy, the moon. See the article **MOON**.

**LUNA**, among chemists, signifies silver. See **SILVER**.

**LUNAR**, something belonging to the moon; thus we say lunar month, lunar year, lunar dial, lunar eclipse, &c. See the articles **MOON**, **MONTH**, **YEAR**, &c.

**LUNARIA**, moon-wort in botany, a genus of plants whose flower is tetrapetalous and cruciform, it hath six stamina, two of which are shorter than the rest; the fruit is a large, erect, plane, compressed, elliptical pod, opening with two valves, and containing two cells, which inclose a few compressed kidney-shaped seeds.

**LUNATIC**, a person affected with lunacy, the cure of which is to be attempted by evacuations of all kinds; as bleeding, vomiting, cathartics, &c. See **MADNESS**.

**LUNGS**, a part of the human body, which is the cause or instrument of respiration. The lungs are the large viscous of the thorax: they are situated in the two sides of it, with the heart as it were between them; and are connected, by means of the mediastinum, with the sternum and vertebræ; with the heart by means of the pulmonary vessels, and immediately with the aspera arteria. The colour of the lungs, in infants, is a fine florid red; in adults it is darker; and in old people, livid, or variegated with black and white. When inflated, they have some resemblance to the hoof of an ox: and are convex on the upper side, and concave underneath. They are divided into two large lobes, the right and left; the left, which is the smaller, is divided again into three smaller ones. The membrane with which the lungs are surrounded, is continuous with the pleura. The substance of the

## L U R

lungs is spongy, or vesicular, and they seem, indeed, entirely composed of a number of small vessels of a fleshy texture, and of a variety of vessels.

The vessels of the lungs are the bronchia, the bronchial artery and vein, the pulmonary artery and vein, the nerves, and the lymphatics. See **BRONCHIA**, &c.

The uses of the lungs are, 1. To perform the office of respiration, by which the blood is attenuated in the plexus of the arteries called the rete vasculosum. 2. To be assistant to the voice in speaking and to the sense of smelling. They are also emunctories of the blood, and are of many other important services.

**LUNG-WORT**, *Pulmonaria*, in botany. See **PULMONARIA**.

**LUNISOLAR YEAR**, in chronology, a period of years produced by multiplying the cycle of the moon, 19, by 28, that of the sun; the product is 532; in which space of time these luminaries return to the same point in the heavens.

**LUNULA**, in geometry, a plane-figure like a crescent, or half moon, for the quadrature of which, see **QUADRATURE**.

**LUPERCALIA**, in antiquity, a festival of the antient Romans in honour of the god Pan, observed on the fifteenth of February, and so called from the luperi, the priests of that fabulous deity.

**LUPIA**, in surgery, a kind of incysted tumor, called also talpa and testuda. See **ENCYSTED** and **TUMOR**.

**LUPINUS**, *Lupine*, in botany, a genus of plants, the corolla of which is papilionaceous; the vexillum is cordated, roundish, and emarginated; the alæ are oval, and almost of the same length with the vexillum; the carina is divided into two segments at the base: the fruit is a large, oblong, coriaceous, compressed, acuminate pod, containing only one cell, which includes several roundish compressed seeds.

**LUPULMUM**, in botany, a species of trefoil. See the article **TREFOIL**.

**LUPULUS**, the hop, in botany, &c. See the article **HOP**.

**LUPUS**, the wolf, in zoology. See the article **WOLF**.

**LUPUS MARINUS**, the sea-wolf, in ichthyology, constitutes a distinct genus of malacopterygious fishes; with a compressed body, and six or more ossicles in the membrane of the gills. On the back there is only one fin, which extends almost from the head to the tail. It is a very singular fish, growing to four or five feet long.

**LUPUS**, in astronomy, a constellation of the southern hemisphere. See **CENTAUR**.

**LURE**, in falconry, a device of leather, in the form of a bird, with two wings stuck with feathers, and baited with a piece of flesh; wherewith to re-

## L U T

claim or call back a hawk, when at a considerable distance.

**LUSERNE**, or **LUCERNE**. See the article **LUCERNE**.

**LUSTRATION**, in antiquity, sacrifices or ceremonies by which the ancients purified their cities, fields, armies, or people, defiled by any crime or impurity.

**LUSTRE**, the gloss or brightness appearing on any thing, particularly on manufactures of silk, wool, or stuff. It is likewise used to denote the composition or manner of giving that gloss.

The lustre of silks is given them by washing in soap, then clear water, and dipping them in alum-water cold. To give stuffs a beautiful lustre, for every eight pounds of stuff allow a quarter of a pound of linseed; boil it half an hour, and then strain it through a cloth, and let it stand till it is turned almost to a jelly: afterwards, put an ounce and a half of gum to dissolve twenty-four hours; then mix the liquor, and put the cloth into this mixture; take it out, dry it in the shade, and press it: if once doing is not sufficient, repeat the operation. Curriers give a lustre to black leather, first with juice of barberries, then with gum-arabic, ale, vinegar, and Flander's glue, boiled together. For coloured leather they use the white of an egg beaten in water. Moroccos have their lustre from juice of barberries and lemon or orange. For hats, the lustre is frequently given with common water, sometimes a little black dye is added: the same lustre serves for furs, except that for very black furs they sometimes prepare a lustre of galls, copperas, Roman alum, ox's marrow, and other ingredients.

**LUSTRUM**, in Roman antiquity, a general muster and review of all the citizens and their goods, which was performed by the censors every fifth year, who afterwards made a solemn lustration.

**LUTE**, or **LUTING**, among chemists, a mixed, tenacious, ductile substance, which grows solid with drying, and when applied to the junctures of vessels for distillation, stops them up.

When the subject is merely aqueous, linseed meal, ground fine, and well worked up into a stiff paste with the white of an egg, makes a proper luting; it grows hard with heat, and if it happens to crack, it is repaired by a fresh application.

In the distillation of all fermented inflammable spirits and volatile alkaline salts, a paste made of the same meal, well worked up with cold water, answers very well.

In the distillation of mild acids or acetous liquors, a bladder steeped in water, till it grows slimy, makes an excellent luting.

A luting that requires a stony hardness is necessary in the distillation of fossil acids, as vitriol, sea-salt, &c. which is called the philosophical luting, and may be prepared from the calx of copperas and quick-

quick-lime, by boiling the caput mortuum in vitriol, in several parcels of water, till thoroughly washed, then drying the powder and preserving it in a close vessel. This powder is to be rubbed with an equal quantity of quick-lime, and wrought into a paste with the whites of eggs first beat thin; and this luting is immediately to be applied to the vessel, being first a little heated: or beat pure sand and potter's clay together in such proportion with water, till the matter no longer sticks to the fingers; then add a fourth part of common lime, and the drier this is applied, the better, provided it be left ductile, and the cracks are easily stopped up by the same.

To coat vessels in the stronger distillations with a naked fire, beat fat potter's earth and powdered sand with water into a well wrought paste, which will not stick to the fingers, adding a little common lime at the last, and beating them together: then the vessel being exposed to the vapour of hot water, spread the cement all over it equably with the hand, afterwards sprinkle the surface of the coating with hot and dry sand, and let the coat dry slowly in a cool place, minding to fill up the cracks.

The London chemists use for the same purpose sifted wood-ashes, beat up to a due consistence with the white of eggs and a little gum-water. The same service may be performed in a more excellent manner, by a mixture of linseed-oil and cerufs made by insolation or decoction, and afterwards ground upon a marble with fresh cerufs, till the whole be of the consistence of an unguent.

LUTE is also a musical instrument with strings.

LUTHERANS, the Christians who follow the opinions of Martin Luther, one of the principal reformers of the church in the sixteenth century.

LUTHERN, in architecture, a kind of window over the corniche, in the roof of a building, standing perpendicularly over the naked of a wall, and serving to illuminate the upper story.

Lutherns are of various forms, as square, semi-circular, round; called bulls-eyes, flat arches, &c.

LUTRA, the otter, in zoology. See the article OTTER.

LUTUM, among chemists, denotes a lute; and *lutum sapientiæ*, the hermetical seal. See LUTE and HERMETICAL.

LUXATION, *Luxatio*, in surgery, the recess or removal of the moveable extremity of a bone from the hollow or socket in which it naturally moved, accompanied with a hindrance of motion. This removal is either total or partial; the former is a luxation, and the latter a distortion.

LYCANTHROPY, *Lycanthropia*, in physic, a species of madness or melancholy, in which the patients wander about in the night-time, and in every thing imitating the wolves. Some bite and snarl like dogs, and hence it has been called cynanthropy.

The word is derived from the Greek *λυκος*, a wolf, and *ανθρωπος*, a man.

LYCEUM, in Grecian antiquity, an academy situated upon the banks of the Ilissus at Athens. It was composed of porticos and walks, where Aristotle taught philosophy; walking there constantly every day till the hour of anointing, whence he and his followers were called Peripatetics. See PERIPATETICS.

LYCHNIDEA, in botany. See the article PHLOX.

LYCHNIS, campion, in botany, a genus of plants whose flower consists of five petals, the ungues of which are of the same length with the cup, with a plane broad border: it hath ten filaments alternately ranged, and terminated with incumbent antheræ: the fruit is an oblong, oval, unilocular capsule, opening with five valves, containing a number of roundish seeds.

A species (commonly called scarlet-lychnis) is cultivated in our gardens for the sake of its beautiful flowers; it is propagated by sowing its seeds in the spring, and afterwards transplanted where they are to remain: a variety of this species, producing double flowers, is increased by parting the roots in autumn, or from cuttings in June.

LYCIUM, box-thorn, in botany, a genus of plants, whose flower is monopetalous and infundibuliform; the tube is cylindraceous and incurved, and the limb divided into five obtuse segments: the stamina are five very short filaments, topped with erect antheræ: the fruit is a roundish bilocular berry, containing a number of kidney-shaped seeds.

LYCODONTES, in natural history, the petrified teeth of the *lupus piscis*, or wolf-fish, frequently found fossil. They are of different shapes, but the most common kind rise into a semi-orbicular form, and are hollow within, somewhat resembling an acorn cup: this hollow is found sometimes empty, and sometimes filled with the stratum in which it is immersed. Many of them have an outer circle, of a different colour from the rest.

LYCOPERDON, puff-ball, in botany, a genus of funguses, of a fleshy substance like other mushrooms, and roundish shape. They are sometimes sessile, and sometimes stand on a thick pedicle: they produce separate male and female flowers, contained in the cellular fungous substance, which remains a long time confused, and the fructifications not formed: and when they are formed, and the cells distinct, it is but a very short time before the very matter of the cells breaks to powder, and the seeds fall out of the cavities of the placenta; and the whole matter, powder, seeds, and filaments, of the placenta, are discharged altogether in form of a fine dust.

Of this genus there are a great many species, the most remarkable of which is the starry-lycoperdon, with multifid rays, and a stellated osculum.

LYCO-

# LYN

**LYCOPODIUM**, wolf's-claw-moss, in botany, a genus of mosses consisting of branches, furnished with leaves, and producing spikes, formed of squamæ of a different figure from the leaves, at the bases of which are placed bivalvular kidney-shaped antheræ, which is the only discoverable part of the male flowers; the female flower consists of a tetraphyllous calyx, without a pistillum; and the seeds are only a naked corculum, without cotyledon or tunic.

**LYCOPUS**, water hore-hound, in botany, a genus of plants, the flower of which is monopetalous; the tube is cylindraceous, and the border cut in four obtuse segments: it hath two filaments, topped with small antheræ: there is no pericarpium; but the seeds, which are roundish and four in number, are placed in the bottom of the cup.

**LYING-TO**, or **LYING-BY**, in navigation, arranging the sails in such a situation that they counteract each other nearly with equal effort, some of them drawing her forward, and others forcing her back; the effect of which is, that she makes no way through the sea, only a very little to the leeward. The intent of lying by, in general, is to wait for some ship or boat which is approaching or expected; or in the night time to prevent running on land, shoals, or in the way of danger apprehended to be near.

**LYING-TO in a Storm**, is going with a very little sail to keep the ship from rolling violently, and is more properly expressed trying. See **TRYING**.

**LYMPH**, *Lympha*, a fine fluid, separated in the body from the mass of blood, and contained in peculiar vessels.

**LYMPHATICS**, or **LYMPHEDUCTS**, in anatomy, fine small vessels that convey the lymph.

**LYNX**, or **OUNCE**, in zoology, a species of the felis kind, with a truncated tail, a brown body spotted with black; the head is large, but not very

# LYT

long; the forehead is flat; the eyes are very large and fierce; the ears are very large and open, but they terminate in a point at the top, and are there ornamented with a pencil of fine black hairs; the mouth is furnished with very terrible teeth, and there are whiskers about it, as also over the eyes; the neck is long and thick, the breast large and broad, the legs strong, the claws terrible, the tail short and abrupt; and the whole animal large and robust, somewhat less than the lion, very fierce, and remarkable for the quickness of its sight.

**LYRE**, *Lyra*, a musical instrument of the string kind, much used by the ancients. See **CITHARA**.

The lyre, among poets, painters, statuaries, carvers, &c. is attributed to Apollo and the Muses.

**LYRE**, *Lyra*, in astronomy, a constellation of the northern hemisphere, the number of whose stars in Ptolemy's and Tycho's catalogues are only ten, but nineteen in the Britannic catalogue.

**LYRIC**, in general, signifies something sung or played on the lyre; but it is more particularly applied to the ancient odes and stanzas, answering to our airs and songs, and may be played on instruments.

**LYSIMACHIA**, loose-strife, in botany, a genus of plants whose flower is monopetalous and rotated; the limb is divided into five oblong, oval, spreading segments; it hath subulated filaments topped with acuminate antheræ: the fruit is a globose unilocular capsule, opening with ten valves, and contains a number of angulated seeds: the receptacle is large, globose, and punctated.

**LYTHRUM**, willow-herb, in botany, a genus of plants, the corolla of which consists of six oblong, obtuse, patent petals, inserted by their unguis into the indentures of the cup; it hath ten slender stamina; and the fruit is an oblong-acuminate capsule, having two cells, which are filled with a great number of small seeds.

# M.

## M A C

**M**, A liquid consonant, and the twelfth letter of the alphabet.

The sound of this letter is formed by shutting the lips, and thereby intercepting the breath, as it is strongly expressed through the mouth and nostrils jointly. Its sound is always the same in English; it suffers no consonant after it in the beginning of words and syllables, unless in some derived from the Greek, as *amnesty*, &c.

M. in prescription, signifies a maniple, or hand-ful; and at the end of a receipt it imports *misc*, or mingle.

M, in astronomy, &c. denotes meridional, southern; sometimes *meridies*, or mid-day.

M, in law, the brand of a person convicted of manslaughter, and admitted to the benefit of the clergy; it is burnt on the brawn of the left thumb.

M, among the ancients, was a numeral letter, signifying one thousand; and when a dash was added at the top of it, as  $\overline{M}$ , it signified a thousand times a thousand.

MABBY, according to Mr. Boyle, is a kind of wine made from potatoes, and said to be used in Barbadoes.

MACAO, or MACAW, in ornithology, a name given to the larger species of parrots with very long tails.

MACARONIC, or MACARONIAN, an appellation given to a burlesque kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue latinized.

MACCABEES, two apocryphal books of Scripture: so called from Judas Mattathias, surnamed Maccabeus. The first book of the Maccabees is an excellent history, and comes nearest the style and manner of the sacred historians of any extant. It contains the history of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high-priest; that is, from the year of the world 3829 to the year 3869, 131 years before Christ. The second book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria, to exhort

## M A C

them to observe the feast of the dedication of the new altar, erected by Judas on his purifying the temple. After these epistles follows the preface of the author to his history, which is an abridgement of a larger work, composed by one Jason, a Jew of Cyrene, who wrote the history of Judas Maccabeus, and his brethren, and the wars against Antiochus Epiphanes, and Eupator his son. The second book does not, by any means, equal the accuracy and excellency of the first. It contains a history of about fifteen years, from the execution of Heliodorus's commission, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas Maccabeus over Nicanor; that is, from the year of the world 3828, to the year 3843, 147 years before Christ.

MACE, *Macis*, the second coat or covering of the nutmeg.

It is a thin and flat membranous substance, of an oleaginous nature, a yellowish colour, extremely fragrant, and of a pleasant, but acrid and oleaginous taste. It is to be chosen new, not dry, and of a fragrant smell, tough, oleaginous, and of a good yellow.

Mace is carminitive, stomachic, and astringent; it possesses all the virtues of the nutmeg, if taken in a larger dose; and people have become delirious, for some hours, after an immoderate use of it. The oils of mace and nutmeg, whether prepared by distillation or by expression, are so much of the same nature, that they may be indiscriminately used for one another on all occasions. They give ease in cholics, and often in nephritic cases; taken internally from one drop to five or six of the distilled oil, or an unequal quantity of the expressed; and externally, they are of use to rub up paralytic limbs; they also assist digestion, and will often stop vomitings and hiccoughs, only by being rubbed on the regions of the stomach. The nurses have a custom of applying oil of mace, by expression, to children's navels to ease their gripes, and that often with success; and we are assured by authors of cred- it, that, rubbed on the temples, it promotes sleep.

The oils, by distillation, are very properly added to the stronger cathartics in form of pills, and prove excellent correctives.

**MACERATION**, *Maceratio*, in pharmacy, an infusion or soaking of ingredients in water, &c. in order either to soften them, or extract their virtues. It is a kind of digestion.

**MACHINE**, *Machina*, in general, whatever hath force sufficient to raise or stop the motion of a heavy body.

Machines are either simple or compound; the simple ones are the seven mechanical powers, viz. lever, balance, pulley, axis and wheel, wedge, screw, and inclined plane. See **MECHANICAL POWERS, LEVER, BALANCE, &c.**

If the given power is not able to overcome the given resistance when directly applied, that is, when the power applied is less than the weight or resistance given; then the thing is to be performed by the help of a machine made with levers, wheels, pulleys, screws, &c. so adjusted, that when the weight and power are put in motion on the machine, the velocity of the power may be at least so much greater than that of the weight, as the weight and friction of the machine, taken together, is greater than the power. For on this principle depends the mechanism or contrivance of mechanical engines used to draw or raise heavy bodies, or overcome any other force; the whole design of these being to give such a velocity to the power in respect of the weight, as that the momentum of the power may exceed the momentum of the weight. For if machines are so contrived, that the velocity of the agent and resistant are reciprocally as their forces, the agent will just sustain the resistant; but with a greater degree of velocity will overcome it. So that if the excess of velocity in the power is so great as to overcome all that resistance which commonly arises from the friction or attrition of contiguous bodies, as they slide by one another, or from the cohesion of bodies that are to be separated, or from the weights of bodies to be raised; the excess of the force remaining, after all these resistances are overcome, will produce an acceleration of motion proportional thereto, as well in the parts of the machine, as in the resisting body.

**MACHINERY**, in epic and dramatic poetry, is when the poet introduces the use of machines, or brings some supernatural being upon the stage, in order to solve some difficulty, or to perform some exploit out of the reach of human power. The ancient dramatic poets never made use of machines, unless where there was an absolute necessity for so doing; whence the precept of Horace,

*Nec Deus interfit, nisi dignus vindice nodus inciderit.*

It is quite otherwise with epic poets, who introduce machines in every part of their poems; so that nothing is done without the intervention of the

gods. In Milton's *Paradise Lost*, by far the greater part of the actors are supernatural personages: Homer and Virgil do nothing without them; and in Voltaire's *Henriade*, the poet has made excellent use of St. Louis.

As to the manner in which these machines should act, it is sometimes invisibly, by simple inspirations and suggestions; sometimes by actually appearing under some human form; and, lastly, by means of dreams and oracles, which partake of the other two. However, all these should be so managed as to keep within the bounds of probability.

**MACKREL**, in ichthyology, a species of scomber, with five pinnules at the extremity of the back, and a spine at the anus.

**MACROCOSM**, the great world, or universe.

The word is Greek, *μικροκοσμος*, and derived from *μικρος*, great, and *κοσμος*, the world.

**MACROLOGY**, in rhetoric, a too copious style. See the article **STYLE**.

**MACULÆ**, in astronomy, dark spots appearing on the luminous faces of the sun, moon, and even some of the planets; in which sense they stand contradistinguished from faculæ. See the article **FACULÆ**.

These spots are most numerous and easily observed in the sun. It is not uncommon to see them in various forms, magnitudes, and numbers, moving over the sun's disk. They were first of all discovered by the Lyncean astronomer Galileo, in the year 1610, soon after he had finished his new invented telescope. That these spots adhere to, or float upon, the surface of the sun, is evident for many reasons. 1. Many of them are observed to break out near the middle of the sun's disk; others to decay and vanish there, or at some distance from his limb. 2. Their apparent velocities are always greatest over the middle of the disk, and gradually slower from thence on each side towards the limb. 3. The shape of the spots varies according to their position on the several parts of the disk: those which are round and broad in the middle, grow oblong and slender as they approach the limb, according as they ought to appear by the rules of optics.

By comparing many observations of the intervals of time in which the spots made their revolution, by Galileo, Cassini, Scheiner, Hevelius, Dr. Halley, Dr. Derham, and others, it is found that 27 days, 12 hours, 20 minutes, is the measure of one of them at a mean; but in this time the earth describes the angular motion of  $26^{\circ} 22'$ , about the sun's center: therefore say, as the angular motion of  $360^{\circ} + 26^{\circ} 22'$ , is to  $360^{\circ}$ ; so is 27 days, 12 hours, 20 minutes, to 25 days, 15 hours, 16 minutes; which, therefore, is the time of the sun's revolution about its axis.

As to the magnitude of the spots, they are very considerable, as will appear if we observe that some of them are so large as to be plainly visible to the

naked eye; thus Galileo saw one of them in the year 1612; and Mr. Martin assures us, that he knew two gentlemen that thus viewed them within a few years past; whence he concludes, that these spots must therefore subtend, at least, an angle of one minute. Now the diameter of the earth, if removed to the sun, would subtend an angle of but  $20''$ ; so that the diameter of a spot, just visible to the naked eye, is, to the diameter of the earth, as 60 to 20, or as three to one; and, therefore, the surface of the spot, if circular, to a great circle of the earth, is as 9 to 1; but four great circles are equal to the earth's superficies; whence the surface of the spot is, to the surface of the earth, as 9 to 4, or as  $2\frac{1}{4}$  to 1. Gassandus says, he saw a spot whose diameter was equal to  $\frac{1}{20}$  of that of the sun, and therefore subtended an angle at the eye of  $1' 3''$ ; its surface was therefore 5 times larger than the surface of the whole earth.

What these spots are, it is presumed, no body can tell; but they seem to be rather thin substances than solid bodies, because they lose the appearance of solidity in going off the disk of the sun: they resemble something of the nature of scum or scoria, swimming on the surface, which are generated and dissolved by causes little known to us: but whatever these solar spots are, it is certain they are produced from causes very inconstant and irregular; for Scheiner says he frequently saw fifty at once, but for twenty years after scarce any appeared. And in this century the spots were very frequent and numerous till the year 1741, when, for three years successively, very few appeared; and now, since the year 1744, they have again appeared as usual.

These maculæ are not peculiar to the sun, they have been observed in all the planets. Thus Venus was observed to have several by signior Bianchini, in the year 1726. As in Venus, so in Mars, both dark and bright spots have been observed, first by Galileo, and afterwards by Cassini, &c. Jupiter has had his spots observable ever since the invention and use of large telescopes. Saturn, by reason of his great distance on one hand, and Mercury, by reason of his smallness and vicinity to the sun on the other, have not as yet had any spots discovered on their surfaces, and consequently nothing in relation to their diurnal motions and inclinations of their axis to the planes of their orbits can be known, which circumstances are determined in all the other planets, as well as in the sun, by means of these maculæ. See the articles VENUS, MARS, and JUPITER.

The spots, or maculæ, observable on the moon's surface, seem to be only cavities or large caverns, on which the sun shining very obliquely, and touching only their upper edge with his light, the deeper places remain without light; but as the sun rises higher upon them, they receive more light, and the shadow, or dark parts grow smaller and shorter,

till the sun comes at last to shine directly upon them, and then the whole cavity will be illustrated: but the dark, dusky spots, which continue always the same, are supposed to proceed from a kind of matter or soil which reflects less light than that of the other regions. See MOON.

MAD-APPLE, in botany. See the article MELONGENA.

MADWORT, *Alysson*, in botany. See the article ALYSSON.

MADDER, *Rubia*, in botany, a genus of plants, whose flower is monopetalous, campanulated, and divided into four segments; it hath four subulated filaments, which are shorter than the corolla; these are topped by simple antheræ. The fruit consists of two smooth berries growing together, each containing a single, roundish, umbilicated seed.

A species called *Rubia tinctorum sativa*, is much cultivated in Holland, the root being necessary for the use of dyers and callico printers, and is so essential to both manufactures, as neither of those businesses can be carried on without this commodity; and the consumption of it is so great here, as that upon a moderate computation, there is annually so much of it imported from Holland, as the price of it amounts to more than one hundred thousand pounds, which might be saved to the public if a sufficient quantity of it was planted in England, where it may be cultivated to greater advantage than in Holland, the land here being better adapted to grow this plant; but as the growing it in quantity has been for several years discontinued with us, so the method of culture is not well known to many persons here; and as there is at present an inclination in the public to regain this lost branch of trade, (for formerly there was not only enough of this commodity raised in England for our own consumption, but also great quantities exported) and the great premiums offered by the Society for the Encouragement of Arts, Manufactures, and Commerce, to those who raise the greatest quantities of this useful plant, we shall therefore give a description of the plant, and the method of culture, as practised in Holland.

The root is perennial, and composed of many long, thick, succulent fibres; these are joined at the top in a head, and is remarkable for its red colour and firm texture; it is somewhat transparent, and has a yellowish pith in the middle, which is tough, and of a bitterish taste: from the root arises many four-cornered, jointed, annual stalks, which in good land will grow five or six feet long, and, if supported, sometimes seven or eight; they are armed with short herbaceous prickles, and at each joint are placed five or six spear-shaped leaves, that surround the stalk in form of a star: from the joints of the stalks come out the branches which sustain the flowers; they are placed opposite by pairs, each pair crossing the other; these have a few small leaves toward

toward the bottom; the branches are terminated by loose branching spikes of yellow flowers, these appear in June, and are sometimes succeeded by seeds, which never ripen in England

The best madder is cultivated in Schowen, one of the islands of Zealand, which is performed in the following manner:

The land which is designed for madder, if it is strong and heavy, is ploughed twice in autumn, that the frost in winter may mellow it and break the clods, then it is ploughed again in the spring, just before the time of planting; but if the ground is light, then it is ploughed twice in the spring, at the last ploughing it is divided into lands of three feet broad, with furrows between each land four or five inches deep. Madder requires a loomy substantial soil, not too stiff and heavy, nor over light and sandy. The time for planting madder begins toward the end of April, and continues all May, and sometimes, in very backward springs, there is some planted the beginning of June. The young shoots from the sides of the roots are taken off from the mother plant, with as much root as possible, and are planted with a dibber in rows at one foot asunder, and commonly four in a row. The first year the madder is planted, it is customary to plant cabbages or dwarf kidney beans in the furrows between the beds; but there is always great care taken to keep the ground clear from weeds. In September or October, when the young madder is cleaned for the last time that season, the green stalks are carefully spread down over the beds, without cutting off any part; and in November it is covered three or four inches with earth.

The second year, in the beginning of April, which is about the time the young shoots spring forth, the earth on the top of the beds should be scuffed over and raked, to destroy the young weeds, and make the surface smooth and mellow. The succeeding summer, there must be the same care taken to keep the madder clean, not admitting any other crop to be with it, and the succeeding autumn they must be earthed as before.

As madder-roots are seldom dug up the second year, but after it has grown three summers, the culture of the last is the same as the former. In September it is dug up and carried to a stove to be dried; which being done sufficiently, it is afterwards pounded, sifted, and put in casks.

When madder is thus prepared and casked, it is, in Zealand, examined by sworn essayers, and tried if it is not faulty packed up, that is, whether in preparing it is properly manufactured, and to see if every part of the cask is filled with madder of equal goodness and quantity, not burned in drying, nor mixed with dirt.

In medicine, the root is attenuant, and has the credit of being a vulnerary of the first rank. It is

given in chronical cases, where there are obstructions of the viscera; and is good in the jaundice, dropsy, and obstructions of the spleen; its dose is from five grains to fifteen, but is seldom given singly. Madder has one very uncommon property, that is, it will turn the bones red of those animals that have fed upon it some time.

**MADNESS**, *Mania*, a most dreadful kind of delirium without a fever.

Melancholy and madness may very justly be considered as diseases nearly allied; for they have both the same origin, that is, an excessive congestion of blood in the brain: they only differ in degree, and with respect to the time of invasion; melancholy being the primary disease, of which madness is the augmentation. Both these diseases suppose a weakness of the brain, which may proceed from an hereditary disposition; from violent disorders of the mind, especially long continued grief, sadness, anxiety, dread, and terror; from close study and intense application of mind to one subject; from narcotic and stupefying medicines; from previous diseases, especially acute fevers; from a suppression of hæmorrhages, and omitting customary bleeding; from excessive cold, especially of the lower parts, which forces the blood to the lungs, heart, and brain; and from violent anger, which will change melancholy into madness.

It is evident from observation, that the blood of maniac patients is black, and hotter than in the natural state; that the serum separates more slowly and in a less quantity than in healthy persons; and that the excrements are hard, of a dark red or greyish colour, and the urine light and thin.

The antecedent signs of madness are a redness and suffusion of the eyes with blood, a tremulous and inconstant vibration of the eye-lids, a change of disposition and behaviour; supercilious looks, a haughty carriage, disdainful expressions, a grinding of the teeth, and unaccountable malice to particular persons; also little sleep, a violent head-ach, quickness of hearing, incredible strength, insensibility of cold; and, in women, an accumulation of blood in the breasts, in the increase of this disorder.

Diseases of the mind have something in them so different from other disorders, that they sometimes remit for a long time, but return at certain periods, especially about the solstices. It may likewise be observed, that the raving fits of mad people, which keep the lunar periods, are generally accompanied with epileptic symptoms.

This disease, when it is primary or idiopathic, is worse than the symptomatic, that accompanies the hysteric or hypochondriac passion, which is easily cured; as is that also which succeeds intermitting fevers, a suppression of the menses, of the lochia, of the hæmorrhoids, or which is occasioned by narcotics. When the paroxysms are slight in the idiopathic

pathic kind, the cure is not very difficult; but if it is inveterate, and has but short remissions, it is almost incurable. Sometimes this disease terminates by critical excretions of blood from the nose, uterus, or anus; sometimes diarrhoeas and dysenteries will terminate these disorders; and pustules, ulcers, and the itch, have also done the same. As to the cure, bleeding is the most efficacious of all remedies; and where there is a redundancy of thick grumous blood, a vein is first to be opened in the foot, a few days after in the arm; then in the jugular vein, or one in the nostrils with a straw; and last of all the frontal vein, with a blunt lancet, for fear of hurting the pericranium. Tepid baths made of rain or river-water are also convenient; and before the patient enters the bath, he should have cold water poured on his head. Purgatives are likewise useful; but the lenient are to be preferred to the drastic: thus manna, cassia, rhubarb, cream of tartar, or tartar vitriolate, are most convenient, when the disease arises from the hypochondriac passion, a stagnation of the blood in the intestines, or in the ramifications of the vena portæ, especially when taken in decoctions and infusions at repeated intervals, so as to operate in an alterative manner. Some kinds of mineral waters are also highly efficacious in melancholy and madness: but nothing is better for removing the cause of these disorders, than depurated mercury. Particular medicines among vegetables, are balm, betony, vervain, brook-lime, sage, worm-blood, flowers of St. John's-wort, of the lime-tree, and camphire; from animals, ass's blood; among minerals, steel, cinnabar, sugar of lead, and the calx and tincture of silver. Hoffman is of opinion, that nothing better deserves the name of a specific in these diseases than motion and exercise, when duly proportioned to the strength of the body. Sative medicines are good, but not opiates and narcotics, for these induce stupidity and folly: these that are good in an epilepsy, will be here beneficial, such as castor, shavings of hartshorn, the roots and seeds of piony, antiepileptic powders, the valerian root, flowers of the lily of the valley, and of the lime-tree. Boerhaave says, the principle remedy for raving madness is dipping in the sea, and keeping the patient there as long as he can bear it. As a high degree of the itch has terminated these disorders, it may be proper to make issues in the back; but blisters, contrary to Shaw's opinion, are prejudicial; for by stimulating the nervous membranes and the dura mater, they increase the spasmodic stricture, and the motion of the gross and bilious blood through the head and the other parts of the body.

As to the diet, the patient should carefully abstain from salt and smoked flesh, whether beef or pork; from shell fish; from fish of a heavy and noxious quality; from aliments prepared with onions and garlic: all which generate a thick blood.

He should, in general, eat no more than is sufficient to support nature. Small beer, or cold pure water, are the best drink; but sweet and strong wines are highly prejudicial, as is also excessive smoking tobacco. Change of air and travelling may be beneficial.

For the madness proceeding from the bite of a mad dog, see HYDROPHOBIA.

MADREPORA, in botany, a genus of submarine plants, of a stony hardness, but somewhat approaching to the form of other vegetables: it is composed of a main stem, and subdivided into a number of branches, which are full of holes or pores, in a radiated form.

MADRIER, in the military art, a long and broad plank of wood, used for supporting the earth in mining and carrying on a sap, and in making coffers, caponiers, galleries, and for many other uses at a siege. Madriers are also used to cover the mouths of petards, after they are loaded, and are fixed with the petards to the gates or other places designed to be forced open.

MADRIGAL, in the Italian, Spanish, and French poetry, is a short amorous poem, composed of a number of free and unequal verses, neither confined to the regularity of a sonnet, nor to the point of an epigram, but only consisting of some tender and delicate thought, expressed with a beautiful, noble, and elegant simplicity. The madrigal is usually considered as the shortest of all the lesser kinds of poetry, except the epigram: it will admit of fewer verses than either the sonnet or the roundelay; no other rule is regarded in mingling the rhimes, and the different kinds of verse, but the fancy and convenience of the author: however, this poem allows of less license than many others, both with respect to rhyme, measure, and delicacy of expression.

MÆMACTERION, *μακμακτιώνιον*, in ancient chronology, the fourth month of the Athenian year, consisting of only twenty-nine days, and answering to the latter part of September and the beginning of October.

MAGAS, in ancient music, the name of two instruments, the one a stringed kind, and the other a kind of flute, which is said to have yielded very high and very low sounds at the same time.

MAGAS also signifies the bridge of any instrument.

MAGAZINE, a place in which stores are kept of arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheelwrights, &c. may be employed in making every thing belonging to the artillery, as carriages, waggons, &c.

MAGAZINE of a Ship of War, a small storehouse in the after or fore part of a ship's hold, where the

the gun-powder is stowed, and filled into cartridges, bombs, grenadoes, &c. by the gunner and his mates, ready for engagement.

MAGDALEN, or *Nuns of St. MAGDALEN*, an order of religious in the Romish church, dedicated to St. Mary Magdalen, and sometimes called Magdalenettes. These chiefly consist of courtezans, who quitting their profession, devote the rest of their lives to repentance and mortification.

MAGI, or MAGIANS, an ancient religious sect in Persia, and other eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and abominating the adoration of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes, or the good god; as darkness is the truest symbol of Arimanius, or the evil god. This religion was reformed by Zoroaster, who maintained that there was one supreme independant Being; and under him two principles or angels, one the angel of goodness and light, and the other of evil and darkness; that there is a perpetual struggle between them, which shall last to the end of the world; that then the angel of darkness and his disciples shall go into a world of their own, where they shall be punished in everlasting darkness; and the angel of light and his disciples shall also go into a world of their own, where they shall be rewarded in everlasting light.

The priests of the magi, were the most skilful mathematicians and philosophers of the ages in which they lived, inasmuch, that a learned man and magian became equivalent terms. The vulgar looked on their knowledge as more than natural, and imagined them inspired by some supernatural power; and hence, those who practised wicked and mischievous arts, taking upon themselves the name of magians, drew on it that ill signification which the word magician now bears among us.

This sect still subsists in Persia, under the denomination of Gaurs, where they watch the sacred fire with the greatest care, and never suffer it to be extinguished. See the article GAURS.

MAGIC, originally signified only the knowledge of the more sublime parts of philosophy; but as the magi likewise professed astrology, divination, and sorcery, the term magic became odious, being used to signify an unlawful diabolical kind of science, acquired by the assistance of the devil and departed souls.

Natural magic is only the application of natural philosophy to the production of surprising, but yet natural effects. The common natural magic, found in books, gives us only some childish and superstitious traditions of the sympathies and antipathies of things, or of their occult and peculiar properties, which are usually intermixed with many trifling experiments, admired rather for their disguise than for themselves. See EXPERIMENTAL PHILOSOPHY.

MAGIC Square, a square figure formed of a series of numbers in arithmetical progression, disposed into such parallel and equal ranks, as that the sums of each row, as well diagonally as laterally, shall be equal.

MAGISTERY, in chemistry, commonly denotes a white powder, prepared of certain substances by precipitation. These substances are either of the mineral kind, as earth, stones, &c. or vegetables, as herbs, resins, &c. or animals, as bones, horns, and crustaceous parts.

The method of preparing it is thus: take the substance from which you design to prepare the magistry, and bruise or break it grossly; then pour thereon a proper liquor, an acid, &c. in order to its solution or extraction. The solution is precipitated by an affusion of the liquor, or by the matter by whose force that of the solvent is blunted: the precipitated powder may be washed, if necessary, with common water, and afterwards gently dried.

MAGISTERY of *Bismuth*, is made by dissolving bismuth in spirit of nitre, and pouring on it salt water, which precipitates the magistry to the bottom.

MAGISTERY of *Lead*, is made by dissolving saccharum saturni in distilled vinegar, and then precipitating it with oil of tartar per deliquium.

MAGISTERY of *Resins*, or resinous extracts of scammony, jalap, &c. are made by dissolving the matter in spirit of wine, and precipitating it with water.

Mr. Boyle takes magistry to consist in a preparation of a body, whereby it is converted, by means of some additament, into a body of a different kind, as when iron or copper is turned into crystals of Mars and Venus.

MAGISTRATE, any public officer to whom the executive power of the law is committed, either wholly, or in part.

MAGNA CHARTA, the great charter of the liberties of England, and the basis of our laws and privileges.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state, by charter: these liberties and privileges were also granted and confirmed by king Henry I. by a celebrated great charter, now lost; but which was confirmed or re-enacted by king Henry II. and king John. Henry III. the successor of this last prince, after having caused twelve men to make enquiry into the liberties of England in the reign of Henry I. granted a new charter, which was the same as the present magna charta; this he several times confirmed, and as often broke; till in the thirty-seventh year of his reign, he went to Westminster-hall, and there, in the presence of the nobility and bishops, who held lighted candles in their hands, magna charta was read, the king all the while holding his hand to his breast, and

at last solemnly swearing faithfully and inviolably to observe all the things therein contained, &c. then the bishops extinguishing the candles, and throwing them on the ground, they all cried out, "Thus let him be extinguished, and sink in hell, who violates this charter." It is observed, notwithstanding the solemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war against him, when, after various success, he confirmed this charter, and the charter of the forest, in the fifty-second year of his reign. This excellent charter, so equitable and beneficial to the subject, is the most ancient written law in the kingdom: by 25 Edw. I. it is ordained, that it shall be taken as the common law; and by 43 Edw. III. all statutes made against it are declared to be void.

**MAGNESIA**, or **MANGANESE**, in natural history. See **MANGANESE**.

**MAGNESIA ALBA**, in the materia medica, a fine white earth, soluble readily in all acids, the vitriolic as well as the others, into a bitter purgative liquor; and not convertible by fire into quick-lime.

This earth has not hitherto been found naturally pure or in a separate state: it was for several years a celebrated secret in the hands of some particular persons abroad, till its preparation was made public by Lancisi in the year 1717, and afterwards by Hoffman in 1722. It was then extracted from the mother-ley, or the liquor which remains after the crystallization, of rough nitre; either by precipitation with a solution of fixed alkaline salt; or by evaporating the liquor, and calcining the dry residuum, so as to dissipate the acids, by which the earth had been made dissoluble.

The magnesia, in this mother-ley, appears to have proceeded from the vegetable ashes, which are either made ingredients in the compositions from which nitre is obtained, or else added to the elixation of the nitre: for the ashes of different woods, burnt to perfect whiteness, and freed from their alkaline salt, were found to be of the same nature with the true magnesia. But as quick-lime also, in most of the German, French, and other European nitre-works, is commonly employed in large quantity, the earth obtained from the mother-leys of those works is rather a calcareous earth than magnesia. What is now brought from abroad, under the name of magnesia, gives plain proof of its calcareous nature, by its burning into quick-lime, and forming a selenites with the vitriolic acid.

The true magnesia is obtained in great purity, from a filtered solution of sal catharticus amarus; by adding a filtered solution of any alkaline salt, till a fresh addition produces no farther milkiness. The white earth, which precipitates, is to be washed by repeated affusions of hot as well as cold water, and then dried for use.

The magnesia is recommended by Hoffman as an useful antacid, a safe and inoffensive laxative in doses of a dram or two, and a diaphoretic and diuretic, when given in smaller doses, as fifteen or twenty grains. Since this time, it has of late come into great esteem among us, particularly in heartburns, and for preventing or removing the many disorders which children are thrown into from a redundancy of acid humours in the first passages. It is preferred, on account of its laxative quality, to the testaceous and other absorbent earths, which, unless gentle purgatives are given occasionally to carry them off, are apt to lodge in the body, and occasion a costiveness very detrimental to infants. It must be observed, however, that it is not the magnesia itself which proves laxative, but the saline compound resulting from its coalition with acids: if there are no acid juices in the stomach to dissolve it, it has no sensible operation, and in such cases it may be rendered purgative by drinking any kind of acidulous liquors after it. All the other known soluble earths yield with acids, not purgative, but more or less astringent compounds.

**MAGNET**, *Magnes*, loadstone, in natural history, a very rich iron ore, found in large detached masses, of a dusky iron grey, often tinged with brownish or reddish, and when broken appearing something like the common emery, but less sparkling. It is very heavy, considerably hard, of a perfectly irregular and uneven surface, and of a firm structure, but usually with some porous irregularities within. It is found in England, and all other places where there are iron mines.

The word is derived from a city in Lydia, called Magnesia, where this stone was first found.

This famous stone was well known to the ancients, but scarce any other property of it than that of its attracting iron, as we may see in Pliny, B. 36. c. 16. However, it appears, that they knew something of its communicating virtue, particularly Plato, when describing that famous chain of iron rings put together, the first of which was held by a magnet; and Lucretius makes mention of the same magnetic quality operating through the hardest bodies.

But we do not see by any passage in their writings, that they knew any thing of the directive virtue of the loadstone: and we are utterly in the dark as to the time this discovery was first made, as also when it was applied to the use of navigation. It, however, appears, that this discovery was made before the year one thousand one hundred and eighty.

The primary properties of the loadstone are the following: 1. Every loadstone has two points, called poles, which emit the magnetic virtue. 2. One of these poles attracts, the other repels iron, but no other body. 3. This virtue, being the third species of attraction, is communicated to iron very copiously by the touch, which renders it strongly

strongly magnetic. 4. A piece of iron so touched by the loadstone, and nicely suspended on a sharp point, will be determined to settle itself in a direction nearly north and south. 5. The end of the needle touched by the south pole of the stone, will point northwards; and the contrary. 6. Needles touched by the stone, will dip below the horizon, or be directed on the touched part to a point within the earth's surface: this is called the dipping needle. 7. This virtue may also be communicated to iron by a strong attrition all one way. 8. Iron rods or bars acquire a magnetic virtue by standing long in one position. 9. Fire totally destroys this virtue, by making the stone or iron red hot. 10. This power is exerted sensibly to the distance of several feet. 11. It is sensibly continued through the substance of several contiguous bodies or pieces of iron. 12. It pervades the pores of the hardest body. And, 13. equally attracts the iron in vacuo as in open air. These and many more are the properties of a body, not more wonderful than useful to mankind. See the articles POLE, NEEDLE, VARIATION, &c.

The cause of the variation of the needle has remained hitherto without any demonstrative discovery; yet since its declination, and inclination, or dipping, do both of them manifestly indicate the cause to be somewhere in the earth, it has given occasion to philosophy to frame hypotheses for a solution, which makes the earth a large or general magnet or loadstone, of which all the lesser ones are but so many parts or fragments, and being possessed of the same virtue, will, when left to move freely, have the same disposition and similarity of position, and other circumstances.

The most considerable of these hypotheses is that of the late sagacious Dr. Halley, which is this: the globe of the earth is one great magnet, having four magnetical poles or points of attraction, near each pole of the equator two; and that in those parts of the world which lie near adjacent to any one of those magnetical poles, the needle is chiefly governed thereby, the nearest pole being always predominant over the more remote one. Of the north poles, that which is nearest to us he supposes to be in the meridian of the land's end, which governs the variations in European Tartary and the North Sea; the other he places is a meridian passing through California, about 15 degrees from the north pole of the world, which governs the needle in North America, and the oceans on either side. In like manner he accounts for the variations in the southern hemisphere. See Philosophical Transactions, N<sup>o</sup>. 148.

The variation of the needle from the north and south points of the horizon not being the same, but variable in different years, and in a diverse manner, in different parts of the earth, made the doctor farther conjecture, that two of the magnetic poles were fixed, and two moveable; and in order to make this

out, he supposes the external part of the earth to be a shell or cortex, containing within it a magnetic moveable nucleus of a globular form, whose center of gravity is the same with that of the earth, and moveable about the same axis.

Now, if the motions of both the shell and nucleus were the same, the poles of each would always have the same position to each other; but he supposes the motion of the nucleus to be a very small matter less than that of the shell, which yet is scarce sensible in 365 revolutions; and, if so, the magnetic poles of the nucleus will by slow degrees change their distance from the magnetic poles of the shell, and thus cause a variation in that needle's variation, which is governed by the moveable pole of the nucleus, while that variation which respects the fixed poles of the magnetic shell remains more constant; as in Hudson's-bay the change is not observed to be near so fast as in these parts of Europe.

The variation of the needle has, within a century past, undergone a remarkable alteration; for at London it was observed by Mr. Burrows, in the year 1580, to be  $11^{\circ} 15'$  east; after that, in the year 1622, it was observed by Mr. Gunter to be but  $6^{\circ}$  east. In the year 1634, Mr. Gellibrand observed it to be  $4^{\circ} 5'$  east. In 1657, it was observed by Mr. Bond to be nothing at all, that is, the needle pointed directly to the north. After this, in the year 1672, Dr. Halley observed it to be  $2^{\circ} 30'$  westward; and again, in the year 1692, he found it  $6^{\circ}$  west. Since then, in the year 1722, Mr. Graham, by most accurate experiments, found it to be  $14^{\circ} 13'$ , and at present it is between 19 and 20 degrees; and in some places it has been found to be  $23^{\circ}$  westward.

The ingenious Muschenbroeck has, with indefatigable pains and application, made experiments of the attractions and repulsions of loadstones in respect to iron and to each other, but could never find any regular proportion in the increase of attraction in their approach to, or decrease of attraction in their recess from, one another; only that the force of the magnetic virtue did increase in the approach to, and diminish in the recess from, the stone, but not exactly as the distance, nor as the square or cube of the distance, nor as the square or cube of the distance reciprocally, nor in any proportion reducible to numbers; and therefore he very reasonably conjectures, that the repulsions and attractions disturb one another, so as to confound the proportion; nor are we able to hope for any other rule concerning this matter, till a way be found, if ever it can be, of separating the attracting from the repelling parts.

The poles of a loadstone are not to be looked upon as two such invariable points as never to change place; for according to Mr. Boyle, the poles of a little bit of magnet may be changed by applying them to the more vigorous poles of another, as has been confirmed by Dr. Knight, who

can change at pleasure the poles of a natural magnet, by means of iron bars magnetically impregnated. Upon gently cutting a magnet through the middle of its axis, each piece becomes a complete magnet; for the parts that were contiguous under the equator before the magnet was cut, become poles, and even poles of different names; so that each piece may become equally a north or south-pole, according as the section was made nearer the south or north-pole of the large magnet; and the same thing would happen in any other sub-divisions. But upon cutting a magnet longitudinally, there will then be four poles, the same as before the cutting; only that there shall be formed in each piece a new axis parallel to the former, and more or less in the inside of the magnet. We find by experience, that two magnets attract each other by the poles of different denominations; whereas, on the contrary, the two similar poles repel each other.

By a great number of experiments we also learn that the force of a magnet in attraction and repulsion reaches sometimes farther, sometimes not so far. The activity of some reaches to 14 feet, and that of others is insensible within 8 or 9 inches; the sphere of activity is greater on certain days than on others, without its ever appearing that the heat, moisture, or drought of the air contribute any thing to this effect.

No solid or fluid body can any way hinder the mutual action of iron and a magnet upon each other, unless it be iron itself: nor does the excessive heat of iron diminish these effects, though the excessive heat of a magnet diminish its virtue, at least for a time.

The attraction of a magnet newly dug out of a mine, makes it to take up only very small pieces of iron; for which reason it must be armed in order to augment its force: besides this, the arming it unites, directs, and condenses its virtue towards its poles, and causes its emanations to tend entirely towards the mass which is laid thereon.

When you have determined where the poles are, which you may exactly find by placing over the magnet a very fine short needle, which will stand perpendicular over each pole, and no where else; then you must file it very smooth at its poles, so that the axis shall have the greatest length, yet without too much diminishing its other dimensions. To determine the proportions of the armour, the greater the force of the magnet is, the thicker must the pieces of steel be of which it is to consist; and for this purpose try the magnet with several steel-bars, and the greater weight it takes up with a steel-bar on, that bar is to be its armour. Though the attraction of an armed magnet appears considerable, yet very weak causes destroy its effect in a moment; for instance, when an oblong piece of iron is attracted under the pole of an excellent mag-

net, and the pole of a different denomination in another magnet that is weaker is presented to the lower end of this piece of iron, this weaker magnet will very strongly take away the iron. In like manner, if the point of a needle be put under one of the poles of a magnet so as to hang by its head, and present to this head any bar of iron by its upper end, the needle will immediately quit the magnet, in order to adhere to the bar; but if the needle hold by its head to the pole of the magnet, then neither the bar of iron nor a weak magnet shall disengage it; and there is another slight circumstance which makes an armed and vigorous loadstone appear to have no more force, and that is the two great length of the iron which is to be raised by one of the poles.

In order to communicate the magnetic virtue effectually, these methods are made use of: 1. It has been discovered that iron rubbed upon one of the poles of the magnet, acquires a great deal more virtue than from any other part thereof, and this is more considerable from an armed than a naked magnet. 2. The more gently the iron is pressed, and the more it is pressed against the pole, the more magnetical it becomes. 3. It is more convenient to impregnate iron on one pole than on both successively. 4. The iron is much better impregnated by pressing it uniformly, and in the same direction, according to its length, than by rubbing it by the middle; and the extremity which touches the pole last, retains the most virtue. 5. A piece of polished steel, or a bit of pointed iron, receives more virtue than a simple piece of iron of the same figure; and, *ceteris paribus*, a piece of iron that is long, small and pointed, is more strongly impregnated than that of any other form.

The communication of the magnetic virtue does not sensibly impair that of the loadstone; though it has been observed that some magnets have communicated a greater power to iron to raise weights, than they had themselves, but without impairing their own force, or adding any thing to the weight of the iron.

As several ways have been proposed for recovering the decayed virtue of loadstones, but to little purpose, especially that of keeping the stone constantly in steel filings, we shall here relate the remarkable experiment of Mr. Haac for this purpose, as it was attended with great success. This gentleman had a magnet weighing fourteen ounces and a half, armed, which would take up sixteen times its own weight; but having laid it by for some years unused, it lost one fourth part of its virtue, or more; whereupon he hung as much weight to the stone as it would sustain, and so left it for some weeks; then returning, he applied more weight to the former, which it very easily bore, and then repeating the addition of more weight at several periods, in the space of about two years, he found that the stone

stone had not only recovered its former strength, but increased it so far, that it would now take up more than twenty pounds, whereas at first it would not take up fifteen.

*Artificial MAGNET*, a steel bar impregnated with the virtues of the magnet, so as to possess all the properties, and be used instead of the natural loadstone.

There have been several methods proposed for making artificial magnets, but none has yet met with greater success than that of Mr. Canton's gentleman well known in the learned world, and to whom we owe this discovery.

Procure a dozen of bars, six of soft steel, each three inches long, one quarter of an inch broad, and one twentieth of an inch thick; with two pieces of iron, each half the length of one of the bars, but of the same breadth and thickness: also six pieces of hard steel, each five inches and a half long, half an inch broad and three twentieths of an inch thick; with two pieces of iron, of half the length, but the whole breadth and thickness of one of the hard bars; and let all the bars be marked with a line quite round them at one end. Then take an iron poker and tongs, (pl. LXIX. *fig. 3.*) or two bars of iron, the larger they are, and the longer they have been used, the better; and fixing the poker upright between the knees, hold to it, near the top, one of the soft bars, having its marked end downwards, by a piece of sewing silk, which must be pulled tight by the left hand, that the bar may not slide: then grasping the tongs with the right hand, a little below the middle, and holding them nearly in a vertical position, let the bar be stroked by the lower end from the bottom to the top, about ten times on each side, which will give it a magnetic power sufficient to lift a small key at the marked end; which end, if the bar was suspended on a point, would turn towards the north, and is therefore called the north pole, and the unmarked end is, for the same reason, called the south pole. Four of the soft bars being impregnated after this manner, lay the two (*fig. 1.*) parallel to each other, at the distance of one fourth of an inch, between the two pieces of iron belonging to them, a north and a south pole against each piece of iron: then take two of the four bars already made magnetical, and place them together so as to make a double bar in thickness, the north pole of one even with the south pole of the other; and the remaining two being put to these, one on each side, so as to have two north and two south poles together; separate the north from the south poles at one end by a large pin, and place them perpendicularly with that end downward on the middle of one of the parallel bars, the two north poles towards its south, and the two south poles towards its north end: slide them backward and forward three or four times the whole length of the bar,

and removing them from the middle of this, place them on the middle of the other bar as before directed, and go over that in the same manner; then turn both the bars the other side upwards, and repeat the former operation: this being done, take the two from between the pieces of iron, and placing the two outermost of the touching bars in their room, let the other two be the outermost of the four to touch these with; and this process being repeated till each pair of bars have been touched three or four times over, which will give them a considerable magnetic power, put the half dozen together after the manner of the four, (*fig. 2.*) and touch with them two pair of the hard bars placed between their irons, at the distance of about half an inch from each other; then lay the soft bars aside, and with the four hard ones, let the other two be impregnated, (*fig. 5.*) holding the touching bars apart at the lower end near two tenths of an inch, to which distance let them be separated after they are set on the parallel bar, and brought together again before they are taken off; this being observed, proceed according to the method described above, till each pair have been touched two or three times over; but as this vertical way of touching a bar will not give it quite so much of the magnetic virtue as it will receive, let each pair be now touched once or twice over in their parallel position between the irons, (*fig. 6.*) with two of the bars held horizontally, or nearly so, by drawing at the same time the north of one from the middle over the south end, and the south of the other from the middle over the north end of a parallel bar; then bringing them to the middle again, without touching the parallel bar, give three or four of these horizontal strokes to each side. The horizontal touch, after the vertical, will make the bars as strong as they possibly can be made, as appears by their not receiving any additional strength, when the vertical touch is given by a great number of bars, and the horizontal by those of a superior magnetic power. This whole process may be gone through in about half an hour; and each of the large bars, if well hardened, may be made to lift twenty-eight troy ounces, and sometimes more. And when these bars are thus impregnated, they give to an hard bar of the same size its full virtue in less than two minutes; and therefore will answer all the purposes of magnetism in navigation and experimental philosophy much better than the loadstone, which is known not to have a sufficient power to impregnate hard bars. The half dozen being put into a case (*fig. 4.*) in such a manner as that two poles of the same denomination may not be together, and their irons with them as one bar, they will retain the virtues they have received: but if their power should, by making experiments, be ever so far impaired, it may be

restored without any foreign assistance in a few minutes. And if, out of curiosity, a much larger set of bars should be required, these will communicate to them a sufficient power to proceed with, and they may in a short time, by the same method, be brought to their full strength.

**MAGNIFYING**, in philosophy, the making of objects appear larger than they would otherwise do; whence convex lenses, which have the power of doing this, are called magnifying glasses; and of such glasses are microscopes constructed. See **LENS** and **MICROSCOPE**.

**MAGNITUDE**, whatever is made of parts locally extended, or that hath several dimensions; as a line, surface, solid, &c. See the article **LINE**, &c.

The apparent magnitude of a body is that measured by the visual angle, formed by rays drawn from its extremes to the center of the eye; so that whatever things are seen under the same or equal angles, appear equal; and *vice versa*.

**MAGNOLIA**, the laurel-leaved tulip-tree, in botany, a genus of plants, whose flower corolla consists of nine oblong, obtuse, and concave petals; the filaments are short, acuminate, and numerous, terminated by linear antheræ adhering to every side of the filaments. The fruit is an oval strobilus, composed of compressed, roundish, and almost imbricated capsules, which are unilocular, and contain a kidney shaped seed. All the species of magnolia are natives of Carolina, Virginia, or Florida, they are propagated by seeds, which should be procured from where they grow naturally, and on their arrival should be sown immediately on a moderated hot bed, they may also be raised from layers; and could these beautiful trees be so far naturalized to our climate as to endure the severity of our coldest winters, they would make some of the greatest ornaments of our gardens.

**MAHOMETANS**, those who believe and practise the religion of Mahomet.

The fundamental position on which Mahomet erected the superstructure of his religion, was, that there has been from the beginning of the world but one true orthodox belief, which consists in acknowledging one only true God, and obeying such of his messengers and prophets as he has from time to time sent into the world, to reveal his will to mankind. Upon this foundation he sat up for a prophet to extirpate idolatry, which was the religion of the Arabs, his countrymen, and to reform the other abuses crept into religion. The whole substance of his doctrine he therefore comprehended in these two principal articles of faith, "There is but one God, and Mahomet is his prophet;" in consequence of which last article, all such ordinances and institutions as he thought fit to establish, were to be received as obligatory and of divine authority.

The Mahometans divide their religion into two general parts, faith and practice; of which the first is divided into six distinct branches; belief in God, in his angels, in his scriptures, in his prophets, in the resurrection and final judgment, and in God's absolute decrees. The points relating to practice are, prayer, with washings, &c. alms, fasting, pilgrimage to Mecca, and circumcision. In regard to these practical points, Mahomet, it is said, declared, that the practice of religion is founded upon cleanliness, which is one half of faith, and the key of prayer. Alms-giving is thought to be so pleasing in the sight of God, that the caliph Omar Ebn Abdalaziz used to say, prayer carries us half way to God; fasting brings us to the door of his palace; and alms procure us admission: and Mahomet himself used to say of fasting, that it was the gate of religion; and the odour of the mouth of him who fasteth is more grateful to God than that of musk. Besides these they have some negative precepts and institutions of the koran, in which several things are prohibited, as usury, the drinking of wine, all games that depend upon chance, the eating of blood, and swine's flesh, and whatever dies of itself, is strangled, or is killed by a blow or by another beast. These doctrines and practices Mahomet established by the sword, by preaching, and by the alkoran or koran, which contains the principles of his religion; and he and his followers met with such success, as in a few years to subdue half the known world. See **ALCORAN**.

**MAIDEN**, an instrument used in Scotland for beheading of criminals.

This is a broad piece of iron about a foot square, very sharp on the lower part, and loaded above with a very heavy weight of lead. At the time of execution, it is pulled up to the top of a narrow wooden frame, about ten feet high, and as broad as the engine, with mouldings on each side for the maiden to slide in. A convenience is made about four feet from the ground, for the prisoner to lay his neck; and there is a kind of bar so fastened as to keep him from stirring. The prisoner being thus secured, and the sign given, the maiden is let loose, which in a moment separate his head from his body.

**MAIDEN-ASSIZE**, an assize in which no person is condemned to die.

**MAIDEN-HAIR**, *Adiantum*, in botany, a genus of cryptogamous plants, producing no visible flowers; the seeds are a fine dust, lying in oval spots about the edges of the backs of the leaves, which curl over and cover them. As the leaves of all the species of maiden-hair have one general appearance, it is easy to distinguish them from the other plants of the fern kind; the leaves of all the maiden hairs have a slight sweetish roughish taste, and a pleasant but weak smell, very perceptible when boiling water is poured on them. This plant has long been held

held in esteem against disorders of the breast, for promoting expectoration, softening recent coughs, and allaying the tickling in the throat, occasioned by defluxions of the rheum; for these purposes a syrup of the true sort, flavoured with a little orange flower water, has been usually brought from France, and a syrup of the species which grows in Canada made with maple sugar is sometimes received from America. The virtue of maiden-hair is obtainable however to much better advantage by drinking an infusion of the herb as tea, sweetened either with sugar, or by the addition of a little liquorice. The English maiden-hair has been commonly substituted in the pectoral syrups and infusions made among us; the Canada species, which appears to be superior to the others is said to have been long made use of in France, and has lately been introduced into practice in this country.

**MAJESTY**, a title given to kings, which frequently serves as a term of distinction.

**MAIL**, or *Coat of MAIL*, a piece of defensive armour for the body, made of small iron rings, interwoven in the manner of a net.

**MAIM**, **MAIHEM**, or **MAYHEM**, in law, a wound, by which a person loses the use of a member that might have been a defence to him.

**MAIN**, in the sea language, chief, principal, as the main-mast, main-yard, main-sail, main-hatchway, &c.

**MAIN** also implies some continent or great land, as opposed to island: We steered between the island and the main.

**MAIN-BOWLINES**. See **BOWLINES**.

**MAIN-BRACES**. See **BRACES**.

**MAIN-HATCHWAY**. See **HATCHWAY**.

**MAIN JEARS**. See **JEARS**.

**MAIN-LIFTS**. See **LIFTS**.

**MAIN-MAST**. See **MAST**.

**MAIN-SAIL**. See **SAIL**.

**MAIN-SHROUDS**. See **SHROUDS**.

**MAIN-TYE**. See **TYE**.

**MAIN-YARD**. See **YARD**.

**MAINPRISE**, in law, is the receiving a person into friendly custody, who might otherwise be committed to prison, on security given that he shall be forth-coming at a certain time and place appointed. There is a difference between bail and mainprise, for a person mainprised is said to be at large from the day of his being mainprised, till the day of his appearance, and is not liable to be confined by his sureties: but when a person is let to bail by a judge, &c. till a certain day, he is in law always accounted in the ward of his bail during the time, and they may, if they please, keep him in prison.

**MAINTENANCE**, in law, is an unlawful maintaining or supporting a suit between others, by stirring up quarrels, or interfering in a cause in which the person has no concern.

**MAJOR**, in the art of war, the name of several officers of very different ranks and functions; as, 1. Major-general, the next officer to the lieutenant-general: his chief business is to receive the orders from the general, or in his absence from the lieutenant-general of the day; which he is to distribute to the brigade-majors, with whom he is to regulate the guards, convoys, and detachments. When there are two attacks at a siege, he commands that on the left. He ought to be well acquainted with the strength of each brigade, of each regiment in particular, and to have a list of all the field officers. In short, he is in the army what a major is in a regiment. He is allowed an aid-de-camp, and has a serjeant and fifteen men for his guard. 2. Major of a brigade, the officer who receives the orders from the major-general, and delivers them to the adjutants of the regiments at the head of the brigade; where he takes and marches the detachments, &c. to the general rendezvous. He ought to be an expert captain, to know the state and condition of the brigade, and keep a roll of the colonels, lieutenant-colonels, majors, and adjutants. 3. Major of a regiment, the next officer to the lieutenant-colonel, generally promoted from the eldest captain. He is to take care that the regiment be well exercised, to see it march in good order, and to rally it in case of its being broke. He is the only officer among the foot that is allowed to be on horseback in time of action, that he may the more readily execute the colonel's orders, either in advancing or drawing off the regiment. 4. Major of a regiment of horse, is the first captain, who commands in the absence of the colonel. 5. Town-major, the third officer in a garrison, being next to the deputy-governor. He ought to understand fortification, and hath charge of the guards, rounds, patrols, &c. His business is also to take care that the soldiers arms are in good order; he likewise orders the gates to be opened and shut, and gives the governor an account of all that passes within the place.

There are also aids-major, drums-major, &c. so called from their preheminance above others of the same denomination.

**MAJOR**, in logic, the first proposition of a syllogism. See the article **SYLLOGISM**.

**MAJOR and MINOR**, in music, signify imperfect concords, which differ from each other by a semi-tone minor. See **CONCORD**.

**MAJOR-DOMO**, an appellation formerly given to the steward or master of the king's household.

**MAJORANA**, marjoram, in botany, a low plant, with slender, square, branched, woody stalks, and little, oval, somewhat downy leaves, set in pairs: on the tops grow scaly heads of small whitish labiated flowers, whose upper lip is erect and cloven, the lower divided into three segments. It is sown annually in gardens, for culinary as well as medicinal

cinal uses: the seeds, which rarely come to perfection in England, are procured from the south of France, where the plant is said to be indigenous.

The leaves and tops of marjoram have a pleasant smell, and a moderately warm aromatic bitterish taste. Infusions of them in water, in colour brownish, smell pretty strongly, and taste weakly and unpleasantly of the herb: the blackish green tinctures, made in rectified spirit, have less smell, but a stronger and more agreeable taste. In distillation with water, an essential oil is obtained, amounting, as Hoffman observes, to about one ounce from sixty-four of the leaves slightly dried; when carefully drawn, of a pale yellow colour; by age, or too hasty fire in the distillation, contracting a reddish hue; of a very hot penetrating taste, and in smell not near so agreeable as the marjoram itself: the remaining decoction, thus divested of the volatile aromatic matter, is weakly, but unpleasantly, bitterish and austere. Great part of the aromatic matter of the herb rises also in the inspissation of the spirituous tincture, and impregnates the distilled spirit: the remaining extract is stronger in taste than that made with water, its quantity being less, but has not much of the warmth or flavour of the marjoram.

This plant has been chiefly recommended in disorders of the head and nerves, in uterine obstructions and mucous discharges proceeding from what is called a cold cause, that is, from a laxity and debility of the solids, and a sluggish state of the juices, and in the humoural asthmas and catarrhs of old people. The powder of the leaves, thin distilled water, and the essential oil properly diluted, are agreeable errhines, and accounted particularly useful in pituitous obstructions of the nostrils, and disorders of the olfactory organs.

**MAJORITY**, the greater number of persons.

**MAIZE**, a species of grain so generally used for food in America, that it has obtained the name of Indian corn.

The size of its ear differs greatly, according to the fertility of the soil, and the warmth of the climate in which it is cultivated; but at a medium, it is about a span long, and commonly has eight or more rows of grain, each of which usually contains upwards of thirty seeds, of various colours, as red, white, yellow, blue, olive, greenish, blackish, speckled, striped, &c. sometimes in the same field, and the same ear: but the white and yellow are the most common: nor does this diversity of colours ever reach beyond the outside of the grain, the flour of which always is white, with a little tinge of yellow. These seeds, which are as big as large peas, are round at their outer surface, very smooth, and set extremely close, in straight lines. The ear is clothed and armed with several strong thick husks, which defend it not only from unseasonable rains and the cold of the night, for it does not ripen fully in some places till towards the latter end of Septem-

ber, but also from crows and other birds, which, being allured by the sweetness of the grain before it hardens, flock to it in great numbers, suck through the top of the outer covering, and devour as far as they can reach. In the northern colonies, the stalk of this plant, which contains a remarkable sweet pith, and is jointed like a cane, does not grow near so high as in the southern parts. It has long leaves, almost like flags, at every joint, and at top a bunch of flowers, of various colours, highly pleasing to the eye. The northern Indians, far up in the country, have a species of this grain, called Mohawk's corn, which never grows high, and, though planted in June, ripens in due season. The general time of planting it is between the middle of March and the beginning of June, or, more particularly, from the middle of April to the middle of May.

This plant is seldom cultivated in England for use, though it might probably turn to good account, as was lately experienced by a gentleman in Lincolnshire, who planted this corn in an open field, where it ripened perfectly, and yielded an abundant crop. Large quantities of it are raised in Asia and Africa, in several parts of France, in Italy, and North America.

The English in North-America plough the ground thoroughly before the grain is planted. They seldom, if ever, dung the whole face of the field, but sometimes put a little dung in each hill of corn, if they think the ground requires it.

In order to plant the corn, they make trenches or furrows, with a plough, across the field, at certain distances from each other, and cross these with others of the same distance, which divide the field into squares; and where the trenches intersect, the grain is put in, and covered. Three or four grains are commonly planted for each hill. The intermediate ground is afterwards ploughed at leisure, as the plants grow, and want more loose earth for the roots to spread in. The hills are made at the time of weeding; some loose earth being then hoed up over the roots, and round the stems or stalks of the corn.

The corn is planted at different distances in different places. In the north colonies the maize grows low, seldom exceeding four or five feet in height; and the leaves being proportionable small, the plants do not require so much ground as in the southern colonies, where they frequently rise to fourteen or fifteen feet. The space generally allowed for the lowest plants is three feet, and for the highest, five or six.

The panicles, or tassels, contain the *farina fecundans* of the plant, and therefore should not be cut off till the grain in the ear is filled. If the tassels of a whole field should be cut off before that time, there would be no grain at all in the ears. This has been proved by experience.

In the more southern colonies, where hay is scarce,

scarce, and the leaves of this corn are very large, they cut them off for fodder; but in the northern colonies, where there is plenty of hay, and the leaves of the corn are small, they generally neglect cutting off the tassels, and stripping off the leaves. They are left on the stalks, and the cattle being turned into the fields, after the corn is gathered in, eat what they like of them; but they are not esteemed so good as what has been cut in season.

An easy way of taking the grain out of the ears, is, to rub one against another, holding one in each hand.

When the ears are stripped off their husks, they are reckoned in the best state for preservation; much better than when the grain is rubbed off from the ear; for then, say they, insects can get at the soft part of the grain, and eat into it; which they cannot do while the soft part is connected with the cob in the ear, and the hard flinty part of every grain turned outward, and the grains close to each other.

The manner of using this corn in America is various. It has this advantage over wheat, that substance may be drawn from your corn-fields long before the general harvest; for the green ears roasted are delicate food; and as the corn ripens and grows harder, the ears boiled are good eating with butter and salt. When it is ripe, the corn, parched and ground into meal, is the hunting and war provision of the Indians; being light to carry, and affording good nourishment. They mix a little of it with water, and it needs no other cooking, having already passed the fire in the parching. The grain soaked in water will part with its skin when beat in a large mortar with a wooden pestle; then it is boiled and eaten with milk. Being pounded coarsely, dry, it is also boiled and eaten as rice. Bag puddings, and baked puddings made of it properly, are very good. The meal is also boiled with water, to make what they call a hasty-pudding, which they eat with butter and sugar, or with milk. This hasty-pudding or boiled meal, being mixed with twice as much dry wheat flour, and worked into loaves, makes much better and pleasanter bread than flour alone.

MAKING-UP, among distillers, the reducing spirits to a certain standard of strength, usually called proof, by the admixture of water; which should be either soft and clear-river water, or spring water rendered soft by distillation.

MALACHI, or *the Prophecy of MALACHI*, a canonical book of the Old Testament, and the last of the twelve prophets. Malachi prophesied about three hundred years before Christ reproving the Jews for their wickedness after their return from Babylon, charging them with rebellion, sacrilege, adultery, prophaneness, and infidelity, and con-

demning the priests for being scandalously careless in their ministry; at the same time not forgetting to encourage those pious few, who in that corrupt age, maintained their integrity. This prophet distinctly points at the Messiah, who was suddenly to come to his temple, and to be introduced by Elijah the prophet, that is, by John the Baptist, who came in the spirit and power of Elias or Elijah.

MALACHITES, or MOLOCHITES, in natural history, &c. a species of jasper, supposed to be possessed of amuletic virtues. See JASPER and AMULET.

MALACIA, *μαλακία*, in medicine, is a languishing disorder incident to pregnant women, in which they long sometimes for one kind of food, and sometimes for another, and eat it with an extraordinary greediness. When women labouring under this disorder begin to abstain from the improper and absurd things they were fond of, and with less reluctance use laudible and wholesome aliments, it is an infallible sign of a beginning cure and approaching health. Pregnant women are generally freed from the malacia about the fourth month; but if it continues longer it is dangerous because the peccant humours are deeply rooted. For the cure of this disorder in pregnant women, but few medicines are recommended, for fear of abortion; however, gentle medicines may be used for evacuating and corroborating the stomach. In young women labouring under a chlorosis, this distemper is cured by the same medicines that are proper for removing the chlorosis. See the article CHLOROSIS.

MALACOPTERYGIUS, among ichthyologists, an appellation given to one of the five orders of fishes, from their having the ray of their fins bony, but not pointed or sharp at the extremities, like those of acanthopterygious fishes. See the articles FISH and ICHTHYOLOGY.

MALACOSTOMOUS FISHES, those destitute of teeth in the jaws, called in English leather-mouthed; as the tench, carp, bream, &c.

MALAGMA, a cataplasm. See the article CATAPLASM.

MALANDERS, in farriery, are cracks in the bend of a horse's knee, that discharge a sharp indigested matter; they are often the occasion of lameness, stiffness, and the horse's tumbling.

This distemper is cured by washing the parts with a lather of soap warmed, or old chamber-ley; and then applying over the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off: if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it.

Take of Æthiops mineral half an ounce; white vitriol one dram; soft green soap six ounces. Anoint with this often, but first clip away the hair, and

# M A L

and clear the scabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre-balls may be taken advantageously for a fortnight or three weeks.

**MALE**, *Mas*, among zoologists, that sex of animals which have the parts of generation without the body. See the articles **ANIMAL**, **SEX**, and **GENERATION**.

The term male has also, from some similitude to that sex in animals, been applied to several inanimate things: thus we say, a male flower, a male screw, &c. See the articles **FLOWER** and **SCREW**.

**MALICE**, in law, is a premeditated design to do mischief to another.

**MALIGNANT**, among physicians, a term applied to diseases of a very dangerous nature, and generally infectious: such are the dysentery, hospital fever, &c. in their worst stages.

**MALL**, or **SEA-MALL**, in ornithology, the English name of the lesser gull, with a grey back and spotted neck, and about the size of the common tame pigeon.

**MALLEABLE**, a property of metals, whereby they are capable of being extended under the hammer. See the articles **DUCTILITY** and **METAL**.

**MALLEOLUS**, in anatomy, a name given by anatomists to the inferior extremities of the tibia and fibula.

**MALLET**, a kind of large wooden hammer, used by artificers who work with a chissel, as sculptors, masons, and stone-cutters, whose mallets are commonly round; and by joiners, carpenters, &c. who work with square-headed mallets.

*Caulking* **MALLET**, a mallet used by caulkers to drive oakum into the seams of a ship. See the article **CAULKING**.

*Serving* **MALLET**, among sailors, a mallet used in serving ropes. See the article **SERVICE**.

The use of the mallet is to bind the spun-yarn or other line very tight about the rope, to prevent it from being chafed by friction; two or three turns of the spun-yarn, for this purpose, are wound about the body of the mallet, and while one man passes the spun yarn ball, another binds the turns of it on the rope, by turning the mallet round it, which draws it very tight.

**MALLEUS**, in anatomy, a bone of the ear, so called from its resemblance to a mallet, and in which is observed the head, the neck and handle, which is joined to the membrane of the tympanum. See **EAR**.

**MALLOW**, *Malva*, in botany, a genus of plants, whose flower consists of five petals, vertically cordated, plane and coalescing at their base; the filaments are numerous, and topped with reniform antheræ: the fruit consists of a number of capsules, joined together by an articulation, and of an orbicular depressed figure, separating from one another, and opening inwardly: the receptacle, affixed

# M A L

to the capsules, is columnar, and the seed is solitary and kidney-shaped.

The common mallow is so well-known as to require no description; it is one of the five emollient herbs, being loosening, cooling, and mollifying: a cataplasm of the leaves of this plant, eases the sting of bees or wasps.

*Marsh-MALLOW*, *Althæa*. See **ALTHÆA**.

*Tree-MALLOW*. See **LAVATERA**.

*Vervain-MALLOW*. See **ALCEA**.

**MALMSEY**, a rich kind of wine, so called, as being brought from Malvasia, in the Morea.

**MALOPE**, in botany, a genus of plants the flower of which is like that of the common mallow; the fruit is composed of many cells, which are collected in a head, each containing a kidney-shaped seed.

**MALPHIGHIA**, in botany, a genus of plants, the flower of which is composed of five large, hollow, kidney-shaped petals, with long and linear unguis: the stamina are ten broad subulated filaments, topped with heart-shaped antheræ: the fruit is a large globose berry, containing osseous, oblong, obtuse, and angulated seeds, each having an oblong and obtuse kernel.

**MALT**, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short in the beginning of vegetation.

In making malt from barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a bright brown, or reddish colour. Then, this water being drained away, the barley is removed from the steeping-cistern to the floor, where it is thrown into what is called the wet couch; that is, an even heap, rising to the height of about two feet. In this wet couch, the capital part of the operation is performed; for here the barley spontaneously heats, and begins to grow, shooting out first the radicle, and if suffered to continue, then the plume, spire or blade. But the process is to be stopped short at the eruption of the radicle, otherwise the malt would be spoiled. In order to stop it, they spread the wet couch thin over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thicker each time. After this, it is again thrown into a large heap, and there suffered to grow sensibly hot to the hand, as it usually will in twenty or thirty hours time; then being spread again, and cooled, it is thrown upon the kiln to be dried crisp without scorching.

This is the general process of malting, in which almost every malster has his secret, or particular way of working. But to render the operation perfect, the following cautions must be observed: 1. That the barley be newly threshed, or at least newly winnowed. 2. That it be not mixed, or made up of different sorts. 3. That it be not over steeped in the

## M A L

the cistern, or so long as to make it soft. 4. That it be well drained. 5. That it be carefully looked after in the wet couch, so as to stop the first tendency of the blade to shooting. 6. Another caution is, to turn the wet couch inside outmost, if the barley comes, and shoots more in the middle of the heap than on the sides. 7. To keep it duly turning, after it is out of the wet couch. 8. To give it the proper heating in the dry heap. 9. To dry and crisp it thoroughly upon the kiln, but without a fierce fire, so as to be several days in drying a kiln of pale malt. And if these directions be carefully observed, the malt will always be good.

The method of malting Indian corn, or Virginia wheat, is much less laborious; for if this corn be buried two or three inches deep in the earth, and covered with the loose mould dug up to make room for it, in ten or twelve days the corn will sprout and appear like a green field; at which time, being taken up, and washed or fanned from its dirt, it is immediately committed to the kiln, and by this means it becomes good malt. It is observable of this corn, that both its root and blade must shoot to a considerable length, before it will make malt; and perhaps this is the case in all large-bodied grain.

The importation of malt from beyond the seas is prohibited: and on its being exported, it is not only freed from paying the excise of 6*d.* a bushel, but a bounty is allowed by act of parliament, for which see the article CORN.

Malt-liquors have different names, and different virtues, from the different methods of preparing the malt, whence they are distinguished into pale and brown; and from the various methods taken in brewing the liquors, whence they are divided into ale and beer, strong and small, new and old. See BREWING.

The colour of the liquor, and many of its effects, depend on the manner of drying the malt it is brewed with; that which has the palest tinge, is made with malt but slenderly dried; whereas, that which is high coloured, is made with malt that is high dried, or roasted, as it were, in comparison of the other; and amber ale is made of a mixture of both.

Another difference in the preparations of malt-liquors consists in the larger quantity of hops in beer, and the smaller in ale; for hops add something of an alkaline nature to the liquor, and not only render it more easy of digestion and secretion of the body, but while it is in the liquor, prevent its running into such cohesions as would make it ropy, vapid, and sour. For this reason, Dr. Quincy is of opinion, that for one constitution injured by beer, there are numbers spoiled by ale, which is apt to stuff the vessels with slime and viscosity, to make the body unweildy and corpulent, and to pave the way for cachexies, the jaundice, asthma, and the dropsy. The different degrees of strength in malt-liquors also make them produce different effects.

## M A M

The stronger they are, the more viscid part they carry into the blood: they are therefore, in general, the more wholesome for being small; that is, of such a strength as to carry some degree of warmth into the stomach, but not so as to prevent their being proper diluters of our necessary food. Indeed; people of robust constitutions, who labour very hard, may dispense with reasonable quantities of the strongest; especially as their food is frequently poor and slender enough, the deficiencies of which this supplies; and their continual exercise and strength of body, digests and breaks the viscidities of the drink into convenient nourishment: though, in persons of another habit and way of living, they would only produce obstructions and ill humours. As to the age of these liquors, it has somewhat the same effect as hops, for those that are longest kept, are certainly least viscid; for age, by degrees, breaks their viscid parts, and by rendering them smaller, makes them fitter for secretion.

MALT-SPIRITS. See the articles DISTILLERY and SPIRITS.

*Knights of MALTA*, otherwise called *Hospitallers of St. John of Jerusalem*, a religious military order, whose residence is in the island of Malta. The order consists of three estates, the knights, chaplains, and servants at arms: there are also priests who officiate in the churches, friar-servants, who assist at the offices, and donnes or demicrosses; but these are not reckoned constituent parts of the body: the government of the order is mixed, being partly monarchical, and partly aristocratical: the grand master is sovereign. The knights formerly consisted of eight different languages, but now only seven, the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, those who have a right to be candidates for the dignity of grand master, called grand-crosses, and those who are only knights assistants: they never marry, yet have continued from 1090 to the present time. The knights are received into this order either by undergoing the trials prescribed by statutes, or by dispensation.

MALTHA, in antiquity, a kind of cement, of which there were two sorts, native and facitious; one of the latter sort, much in use, consisted of pitch, wax, plaster, and grease. Another kind used by the Romans in their aqueducts, was made of lime slacked in wine, incorporated with melted pitch, and fresh figs. Natural maltha is a kind of bitumen, wherewith the Asiatics plaster their walls; and which being once set on fire, water makes it burn more fiercely.

MALVA, mallows. See MALLOWs.

MALUS, the apple-tree, in botany. See the article APPLE.

MAMALUKES, the name of a dynasty that reigned in Egypt.

The

The Mamalukes were originally Turkish and Circassian slaves, bought of the Tartars by Melic-faleh, to the number of a thousand, whom he bred up to arms, and raised some to the principal offices of the empire. They killed sultan Moadam, to whom they succeeded.

Others say, that the Mamalukes were ordinarily chosen from among the Christian slaves, and that they were the same thing in a great measure with the Janissaries among the Turks. They never married. They first are said to have been brought from Circassia, and some have supposed that they began to reign about the year 869.

MAMMÆ, the breasts, in anatomy, two eminences, more or less round, situated in the anterior, and a little towards the lateral parts of the thorax; their middle part lying almost opposite to the bony extremity of the sixth rib on each side.

In children of both sexes, and in males of all ages, they are commonly no more than cutaneous tubercles, or soft verticæ of a roundish colour, called papillæ, or nipples; each of them being surrounded by a small, thin, and pretty broad circle, more or less of a brownish colour, and an uneven surface, termed areola.

In females, when come to the age of puberty, which is sometimes sooner, sometimes later, a third part is joined to the two former, which is a convex protuberance more or less round, of about five or six fingers in breadth, the papilla and areola being situated near the middle of the convex surface. This is what is properly termed the mamma, and it may be called the body of the breast, when compared with the other two parts. It increases with age, and is very large in women with child, and in those that give suck. In old age it decreases and becomes flabby, losing its natural consistence and solidity.

The body of the breast is partly glandular, and partly made up of fat; or it is a glandular substance, mixed with portions of the membrana adiposa, the cellular pellicles of which support a great many blood-vessels, lymphatics, and serous or lactiferous ducts, together with small glandular molecule, which depend on the former; all of them being closely surrounded by two membranes, continued from the pelliculæ.

The innermost of these two membranes, which is, in a manner, the basis of the body of the mamma, is thick and almost flat, adhering to the musculus pectoralis major. The second or external membrane is thinner, forming a particular integument for the body of the breast, more or less convex, and adhering closely to the skin.

The corpus adiposum of the breast in particular is a spongy cluster, more or less interlarded with fat, or a collection of membranous pelliculæ, which, by the particular disposition of their outsidés, form a kind of membrane in shape of a bag, in which all

the rest of the corpus adiposum is contained. The anterior or outer portion of this bag, or that which touches the skin, is very thin; but that side next the pectoralis major is thick.

The glandular body contains a white mass, which is merely a collection of membranous ducts, narrow at their origin, broad in the middle, and which contract again as they approach the papillæ, near which they form a kind of circle of communication. They are called ductus lactiferi.

The areola is formed by the skin; the inner surface of which sustains a great number of small glandular molecule, of that kind which Morgagni calls glandulæ sebacæ. They appear very plainly all over the areola, even on the outside, where they form little flat eminences, at different distances, quite round the circle.

These tubercles are perforated by small holes, through which a kind of sebaceous or cheesy matter, more or less liquid, may be squeezed out. Sometimes this is a serous liquor, sometimes a milky serum, and sometimes pure milk, especially in nurses; and I have seen both serous and milky drops come out at the same time.

From thence I am inclined to think, that these holes communicate with the lactiferous ducts, and that the tubercles are a kind of auxiliary papillæ added to the true ones. The different liquors that may be squeezed from the same glandular body, give also room to think that the holes in them communicate by their extremities with several other small holes. The tubercle in the center of the areola is termed papilla, or the nipple: it is of different sizes in different ages and constitutions, and in the different conditions of females in particular. In women with child, or who give suck, it is pretty large, and generally longer and higher than it is thick or broad; and when it happens to be short, it causes great uneasiness to the child.

The texture of the nipple is spongy, elastic, and liable to divers changes of consistence. It seems to be made up principally of ligamentary fasciculi, the extremities of which form the basis and apex of the nipple: these fasciculi appear to be gently folded or curled, their whole length; and if, by drawing the fibres out, these folds be destroyed, they return again as soon as that action ceases.

Between these fasciculi lie seven or eight particular tubes, at small distances from each other, and all in the same direction; these tubes end at the basis of the papilla, in the irregular circle of communication of the lactiferous ducts, and at the apex, in the same number of almost imperceptible holes; and as they are closely united to the elastic fasciculi, they are folded in the same manner with them.

The body of the papilla is covered by a thin cutaneous production, and by the epidermis; its outer surface is uneven, being full of small wrinkles; among

among which, those near the circumference of the nipple seem to have a transverse or annular disposition, which, however, is not uniform.

This disposition seems to be owing to the elastic folds; and from this simple structure it is easy to explain how infants in sucking the nipple, and women in drawing the teats of cows, bring out the milk. For the excretory tubes, being wrinkled in the same manner as the fasciculi, do by these folds, as by so many valves, hinder the milk contained in the ducts from flowing out; but when the nipple is elongated, the tubes lose their folds, and the passage becomes straight. Besides this, when they are drawn with a considerable force, the whole body of the breast is increased in length, and contracted in breadth, and thereby the milk is pressed into the open tubes; and thus, by barely pressing the body of the breast, the milk may be forced toward the nipple, and even through the tubes.

The arteries and veins distributed through the mammae are ramifications of the arteriae and venae mammariae, of which one kind comes from the subclaviae, and are called mammariae internae; the other from the axillares, called mammariae externae.

These vessels communicate with each other, with those near them, and with the vasa epigastrica. The nerves come principally from the costales, and by means of these communicate with the great nervi sympathetici.

The use of the breasts, in the nourishment of children, is well known to the world: but it is not certainly known what the papillae and areolae in men can be designed for. Milk has been observed in them in children of both sexes.

**MAMMEA**, in botany, an ever-green tree, which grows to the height of sixty or seventy feet: the leaves are large and stiff; the flower consists of four roundish concave petals, which spread open; the filaments are subulated and numerous, and top'd with roundish antherae; the fruit is a large carnosé berry, inclosing one, two, or three large oval stones.

It grows in great plenty in the Spanish West-Indies, where the fruit is generally sold in their markets. It is of a yellowish green colour when ripe, very grateful to the palate, and is esteemed one of the best fruits of that country.

**MAMMIFORM**, in anatomy, a name given to apophyses of the bone in the back part of the scull, so called from their resembling a breast.

**MAMMILLARY**, **MAMMILLARIS**, in anatomy, an epithet given to two little protuberances, somewhat resembling the nipples of the breast, found under the four ventricles of the brain, and supposed to be the organs of smelling. These are called apophyses mammillares. There is also a muscle called mammillaris, or mastoides, serving to support the head.

**MAMMOTH'S TEETH**, in natural history, certain large fossil teeth, found in great plenty in Russia, and supposed to have belonged to elephants.

**MAN**, *Homo*, in zoology, is justly ranked at the head of the animal part of the creation; making a distinct genus of that order of quadrupeds, which Linnæus calls anthropomorpha, from their resemblance to the human form.

The same author distinguishes the race of mankind, according to their different colours, into the Europeans, or white men; the Americans, or copper-coloured men: the Asiatics, or tawny coloured men: and those of Africa, or blacks.

**MANATI**, in zoology, an animal called by Linnæus *thrichechus*. See **THRICHECHUS**.

**MANCHINEEL**, *hippomane*, in botany, a large tree growing naturally in the West-Indian islands. It hath a smooth brownish bark; the trunk divides upwards into many branches, which are furnished with oblong leaves about three inches long and an inch and a half broad, ending in acute points slightly serrated on their edges, of a ligid green, and standing on short footstalks. The flowers come out in short spikes at the ends of the branches; they are male and female, and both apetalous; the female flower is succeeded by a large globose fruit (of a yellow colour when ripe) inclosing a rough woody shell, with several cells, which contains in each an oblong seed.

The fruit of the manchineel tree is very dangerous to eat, causing violent inflammations in the mouth and throat; the wood is much esteemed in America, for making cabinets, book cases, &c. being very durable, and taking a fine polish; it is also said that the worms will not eat it. As the trees abound with milky caustic juice, so before they are felled, they make fires round their trunks, to burn out their juice, otherwise those who fell them would be in danger of losing their sight, by the juice flying into their eyes; and wherever this falls on the skin, it will raise blisters; if dropt on linen, it immediately turns the part black, and on being washed will come in holes. It is also dangerous working the wood after it is sawed out, for if any of the saw-dust happens to get in the workman's eyes, it causes inflammations and the loss of sight for some time; to prevent which, when they are working it they generally cover their faces with fine lawn.

**MANDAMUS**, in law, a writ that issues out of the King's-Bench, sent to a corporation, commanding them to admit or restore a person to his office.

**MANDARINS**, a name given to the magistrates and governors of provinces in China, who are chosen out of the most learned men, and whose government is always at a great distance from the place of their birth. Mandarin is also a name given by the Chinese to the learned language of the country; for besides the language peculiar to every province,

vince, there is one common to all the learned in the empire, which is in China what Latin is in Europe; this is called the Mandarin tongue, or the language of the court.

**MANDATE**, in law, a judicial commandment to do something.

**MANDATE**, in the canon-law, a rescript of the pope, commanding an ordinary collator to put the person therein named in possession of the first vacant benefice in his collation.

**MANDRAKE**, *Mandragora*, in botany, a plant, whose root is thick, long, and taper, like those of the parsnip: it runs a considerable depth in the ground; it is sometimes single, and at others divided into two or three branches; it is whitish within, and of a rusty ash-colour without; it hath no stalks, the leaves arising immediately from the root, standing erect at first, but when full grown they spread open and lay on the ground; they are more than a foot in length, and four or five inches broad in the middle, growing narrow towards both ends; of a dark green colour and a fetid scent; between these come out the flowers, upon a short footstalk; these are erect, monopetalous, and campanulated. The fruit is a large globose berry, containing two cells, with a fleshy, convex receptacle; the seeds are numerous, and kidney-shaped. Mandrake grows wild in Italy, Spain, Portugal, and other warm countries. The roots will remain sound fifty years or more: but as to the resemblance to a human form, as many assert, it is nothing but an imposture, owing to persons that would deceive the public, who form the fresh roots of briony into such shapes, and shew them for mandrakes. (See the article *BRYONIA*). Many wonderful things have been said of its virtues by different authors; however, they all agree it is a narcotic, and when taken in too large a dose will produce dangerous symptoms. It is reckoned cooling in external applications, and therefore recommended in inflammations of the eyes.

**MANDREL**, a kind of wooden pulley, making a member of the turner's lathe, of which there are several kinds, as the flat mandrels, which have three or more little pegs or points near the verge, and are used for turning flat boards on; the pin mandrels are those which have a long wooden shank to fit into a large hole made in the work to be turned; hollow mandrels are those hollow of themselves, and used for turning hollow work: screw mandrels for turning screws, &c

**MANE**, the hair hanging down from a horse's neck, which should be long, thin, and fine; and if frizzled, so much the better.

**MANEGE**, or **MANAGE**, the exercise of riding the great horse, or the ground set apart for that purpose; which is sometimes covered, for continuing the exercise in bad weather; and sometimes open,

in order to give more liberty and freedom both to the horsemen and horse.

One way or other we may always suppose a center in the middle of the manege ground, for regulating the rounds and volts. Sometimes this center is distinguished by a pillar fixed in it, to which they tie the horse when he begins to learn: upon the side of the manege other pillars are placed, two by two, in order to teach horses to raise the fore quarters, by tying them with ropes. See *PILLAR*.

**MANES**, in the pagan system of theology, a general name for the infernal deities, or gods of hell.

The ancients comprehended under manes, not only Pluto, Proserpine, and Minos, but the souls likewise of the deceased were taken into the number, and esteemed gods of hell. It was usual to erect altars and offer libations to the manes of deceased friends and relations.

**MANGER**, in the sea-language, a small apartment in the fore-part of a ship, which is fenced on the after-part by a sort of bulk-head or barrier; the use of which is to prevent the water, which rushes in at the hawse-holes, or the holes through which the cable goes, from running aft on the lower decks, which would render them extremely uncomfortable to the men, who eat and sleep there. As soon as the water enters at the hawse-holes, which is always the case when the ship pitches deep forward, it is conveyed away again through the side into the sea by several small pipes or channels, called scuppers. See *SCUPPERS*.

**MANGO TREE**, in botany, the name of a vast tree, forty feet in height, and eighteen in thickness, and spreads its numerous branches all around at a great distance, being always green, and bearing fruit once or twice a year, from six or seven years old to an hundred. It is propagated by incision, or sowing the seed, in Malabar, Goa, Bengal, Pegu, and many other countries in the East-Indies.

The fruit is of a round oblong figure, flat, slightly sinuated, or hollowed at the sides, and shaped much like a kidney, bigger than a goose egg, smooth, shining, first green speckled with white, then inclining to yellow, and at last of a gold-colour: it has a yellowish and succulent pulp, not unlike that of a peach, or rather a plumb, first acid, then acido-dulcid, and pleasant to the taste. Within the pulp is contained an oblong, compressed, and languous stone, thin, yet very hard and tenacious, and including a callous oblong kernel, very like an oblong almond, and of the same bigness, and of a bitterish though not unpleasant taste.

There are various sorts of this fruit, as there are of our apples and pears, which are very different, according to the country where they grow: that species which is without a stone, and is very grateful to the palate, seems to us only a variety or a degenerate fruit. The fruit is cut into slices, and eaten,

eaten, either without wine, or macerated in wine; it is also candied, in order to its preservation. Sometimes they open it with a knife, and fill up the middle with fresh ginger, garlic, mustard, and salt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moist, though the Indian physicians affirm the contrary. We make use of pickled mangoes, which are imported to us, as we do of pickled cucumbers, for sauce to roasted meat. The stones roasted are said to cure a looseness, which Garcius found to be true. The wood of the tree, with cinders, is used for burning the carcases of the Pagans, as being consecrated to this rite; whence it serves also for coffins, in which they reposit their dead; it is but of a soft substance, and of short duration.

The stalks supply the place of arequa or caunga, in the chewing of betel; the same calcined and reduced to powder, take away warts. Of the tender leaves, with the bark of the Avanaque, that is, the ricinis, the seed of the cummin and parpadogam, is made a decoction, which is highly beneficial in the cough, asthma, and other affections of the thorax. The bark of the tree pulverised, and taken in chicken broth, is an excellent dissolvent of extravasated and coagulated blood, occasioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a present remedy against the diarrhoea, dysentery, and tenesmus. Of the gum of the tree, and the flowers of rice, with the addition of a small quantity of opium and pepper, are prepared pills, which also cure all sorts of fluxes of the belly. Of the flour of the dried kernels, the natives have the art of preparing various kinds of food.

**MANGANESE, MAGNESIA**, in natural history, a poor kind of iron ore. See **IRON**.

It is a dense heavy substance in its finest pieces; being composed of a number of broad and thick striae irregularly laid together, and much resembling those of native antimony; in these masses it is sometimes reddish, sometimes of a dark grey, and sometimes of a fine pale light grey, approaching to the colour of the finest polished iron: but there is a less perfect kind, in which the whole mass seems only to consist of a number of irregularly figured pieces, of a brittle and somewhat glossy ore, blended very loosely together.

Manganese is found in great abundance in the German and Swedish mines, as also in France, Italy, and England; but ours is not equal in beauty or goodness to the German. It is recommended by authors as an astringent, and ordered to be given after calcination in hæmorrhages: but it is very improper for internal use. It is of great service, however, to the glassmen, in clearing away the greenish colour from their white glass while in fusion. See **GLASS**.

**MANICHEES**, in church history, a sect of Christian heretics in the third century, the followers of Manes, who made his appearance in the reign of the emperor Probus; pretending to be the Comforter, whom our Saviour promised to send into the world. He taught that there are two principles, or gods, coeternal and independent on each other, the one the author of all evil, and the other, of all good; a doctrine which he borrowed from the Persian Magi. He held that our souls were made by the good principle, and our bodies by the evil one, and that the souls of his followers passed through the elements to the moon, and from thence to the sun, where being purified, they then went to God, and became united with his essence; but as for the souls of other men, they either went to hell, or were united to other bodies. He alledged that Christ had his residence in the sun, the Holy Ghost in the air, Wisdom in the moon, and the Father in the abyss of light. He is also charged with denying the resurrection, and condemning marriage; with teaching that Christ was the serpent that tempted Eve; with forbidding the use of eggs, cheese, milk, and wine, as proceeding from the bad principle; with using a different kind of baptism from that of the church; with teaching that magistrates were not to be obeyed, and with condemning the most lawful wars.

**MANICORDON**, or **MANICHORD**, a musical instrument in the form of a spinnet; the strings of which, like those of the clarichord, are covered with little pieces of cloth, to deaden, as well as to soften their sound; whence it is also called the dumb spinnet. It is much used in nunneries, because the nuns may play upon it without disturbing that silence which they are obliged to observe in their cells.

**MANIFESTO**, a public declaration made by a prince in writing, shewing his intentions to begin a war, or other enterprize, with the motives that induce him to it, and the reasons on which he founds his rights and pretensions.

**MANILLE**, in commerce, a large brass ring in the form of a bracelet, either plain or engraven, flat or round.

Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. These people wear them as ornaments on the small of the leg, and on the thick part of the arm above the elbow.

**MANIPULUS**, in Roman antiquity, a body of infantry, consisting of two hundred men, and constituting the third part of a cohort. See the article **COHORT**.

Among physicians, the term *manipulus* signifies a handful of herbs or leaves, or so much as a man can grasp in his hand at once; which quantity is frequently denoted by the abbreviature, *M*, or *m*.

**MANNA**, in the materia medica, a sweet juice obtained

obtained from certain ash-trees in the southern parts of Europe, particularly in Calabria and Sicily; exuding from the leaves, branches, or trunk of the tree, and either naturally concreted, or exsiccated and purified by art.

Juices of the same nature are collected, in the Eastern countries, from other trees and shrubs: and similar exudations are sometimes found on different kinds of trees in Europe, as particularly on the larch in the Briançonois in Dauphiny. How far the manna juices of different vegetables differ from one another, is not well known; but this much is certain, that one and the same tree affords mannas very considerably different, in their colour, in their taste, and in their disposition to assume a solid concrete form: that is, in their purity, or the greater or less admixture of oily or resinous matter.

The best sort of the officinal or Calabrian manna is in oblong pieces or flakes, moderately dry, friable, very light, of a whitish or pale yellow colour, and in some degree transparent. The inferior kinds are moist, unctuous, and brown. Both sorts are said to be sometimes counterfeited by compositions of sugar, honey, and purgative materials: compositions of this kind, in a solid or dry form, may be distinguished by their weight, compactness, and untransparency, as likewise by their taste, which is sensibly different from that of true manna, and with greater certainty by their habitude to menstrua.

This juice liquefies in a moist air, dissolves readily in water, and by the assistance of heat, in rectified spirit also; the impurities only being left by both menstrua. On inspissating the watery solution, the manna is recovered of a much darker colour than at first. From the saturated spirituous solution, great part of it separates as the liquor cools, concreting into a flaky mass, of a snowy whiteness, and a very grateful sweetness: the liquor remaining after the separation of this pure sweet part of the manna, leaves, on being inspissated, an unctuous, dark-coloured, disagreeable matter, in greater or less quantity, according as the manna made use of was less or more pure.

Manna, in doses of an ounce and upwards, proves a gentle laxative; it operates in general with great mildness, so as to be safely given in inflammatory or acute distempers, where the stimulating purgatives have no place. It is particularly proper in stomachic coughs, or those which have their origin in the stomach; the manna, by its sweetness and unctuousity, contributing to obtund as well as to evacuate the offending humours: in this intention, it is sometimes made into a linctus or lohoch, with equal quantities of oil of almonds and of syrup of violets. See LINCTUS.

In some constitutions, however, it acts unkindly, especially if given in considerable quantity, occasioning flatulencies, gripes, and distensions of the belly;

inconveniencies, which may be generally obviated by a small addition of some grateful aromatic.

MANNER, in painting, a habitude that a man acquires in the three principal parts of painting, the management of colours, lights, and shadows, which is either good or bad, according as the painter has practised more or less after the truth, with judgment and study. But the best painter is he who has no manner at all. The good or bad choice he makes is called *goûte*.

MANNERS, in poetry, the inclinations, genius, and humour, which the poet gives to his persons, and whereby he distinguishes his characters. See CHARACTER.

MANOMETER, or MANOSCOPE, an instrument to shew or measure the alterations in the rarity or density of the air. The manometer differs from the barometer in this, that the latter only serves to measure the weight of the atmosphere, or of the column of air over it; but the former the density of the air in which it is found, which density depends not only on the weight of the atmosphere, but also on the action of heat and cold, &c. Authors, however, generally confound the two together, and Mr. Boyle himself gives us a very good manometer of his own contrivance, under the title of a statical barometer. See BAROMETER.

MANOR, an ancient royalty or lordship, formerly called a barony, consisting of demesnes, services, and a court-baron; and comprehending in it messuages, lands, meadow, pasture, wood, rents, an advowson, &c. It may contain one or more villages, or hamlets, or only a great part of a village, &c.

A manor is a noble kind of fee, granted in part to tenants for certain services to be performed, and partly reserved to the use of the lord's family, with jurisdiction over the tenants, for their farms or estates.

There are capital manors or honours that have other manors under them; and also customary manors granted by copy of court roll, the lords of which have power to hold courts, and grant copies, &c.

MANSION, in law, is the chief dwelling-house of a lord within his fee, or the capital messuage or manor-house.

MANSLAUGHTER, generally termed homicide, is killing a person without premeditated malice.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed over one another, to the height of almost six feet, generally cased with tin, and set upon little wheels, so that in a siege, they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot. See plate LXIX. fig. 7.

There are other sorts of mantelets, covered on the

the top, of which the miners make use to approach the walls of a town or castle.

**MANTLE**, or **MANTLE-TREE**, in architecture, the lower part of the chimney, or that piece of timber which is laid across the jaumbs, and sustains the compartment of the chimney-piece. See **CHIMNEY**.

**MANTLE**, or **MANTLING**, in heraldry, that appearance of folding of cloth, flourishing or drapery, that is in any achievement drawn about the coat of arms. It is supposed originally to be the representation of a mantle, or military habit, worn by the ancient cavaliers over their armour to preserve it from rust; or, as others hold, a short covering only worn over the helmet, which in aftertimes was lengthened, and made to hang from the helmet below the whole shield.

The mantle is always said in blazonry, to be doubled, that is, lined throughout with one of the furs, as ermin, pean, viary, &c.

**MANUFACTURER**, one who works up a natural product into an artificial commodity.

**MANURE**, in agriculture and gardening, any thing that is used to enrich, fatten, and improve land.

There are various kinds of manure proper for the different kinds of land we meet with: if the land is loose and sandy, the mud out of ponds, or strong loam, makes a good manure: matle of the blue kind, and clay of the lighter sort, spread over gravelly or sandy land, are of vast advantage to it, by making it more solid and tenacious; cow-dung and hog-dung are also excellent for hot lands.

If the land is stiff, cold, and clayey, sheep and deers dung are esteemed by some the best manure; likewise the dungs of horses, pigeons, hens, geese, &c. are reckoned excellent; also sea and drift sands, or sea-coal ashes, are good manure for these sort of lands: tanners bark, laid in a heap and rotted, is an excellent manure for stiff cold land; and one load of it will improve the ground more, and last longer, than two loads of any other manure: when this is laid on grass, it should be done soon after Michaelmas, that the winter rains may wash it into the earth; and where it is used for corn land, it should be spread on the surface before the last plowing, that it may be turned down for the fibres of the corn to reach it in the spring. Rotten vegetables, of most sorts, also greatly enrich land; so that, where other manure is scarce, these may be used with great success: thus the weeds of ponds, lakes, and ditches, being dragged out just as they begin to flower, and laid on heaps to rot, will make an excellent manure; but it is to be observed, that in rotting these vegetables, it will be proper to mix some earth, mud, or any other such like substance, with them, to prevent their taking fire in their fermentation: it will also be necessary to cover the heaps with earth, mud, or dung, to detain the salts,

otherwise many of the finer parts will evaporate in fermenting.

The refuse of kitchen-gardens, when laid on heaps and rotted, will also afford good manure for corn land: and also fern, mowed down while it is green and tender, and laid on heaps to rot, will make an excellent manure; and by frequently mowing it, this troublesome plant will be destroyed.

The ashes of all kinds of vegetables are also good manure for lands, so that where the ground is overrun with bushes, brambles, &c. if they are grubbed up in summer, dried, and consumed to ashes, and spread over the land, they will greatly improve it.

Rotten wood, and saw-dust when rotted, are a very good manure for strong lands, as are also bones, horns, shells, woollen-rags, &c. and whatever serves too loosen its parts.

But for all stubborn clayey soils, there is no manure so good as the cleansing of the streets of large cities, the parts of tough land will be more expeditiously separated by this, than any other compost, and, where it is to be had, it is of the greatest value both for field or garden land.

**MANUSCRIPT**, in matters of literature, denotes a written book, in contradistinction to a printed one. See **BOOK**.

**MAP**, a plane figure, representing the surface of the earth, or a part thereof, according to the laws of perspective; distinguishing the situation of cities, mountains, rivers, &c.

In maps, these three things are essentially requisite. 1. That all places have the same situation and distance from the great circles therein, as on the globe, to shew their parallels, longitudes, zones, climates, and other celestial appearances. 2. That their magnitudes be proportionable to the real magnitudes on the globe. 3. That all places have the same situation, bearing, and distance, as on the earth itself.

Maps are either universal, which exhibit the whole surface of the earth; or particular, which exhibit some particular part thereof: each kind is called geographical or land maps, in contradistinction to hydrographical or sea maps, representing the seas and sea coasts, properly called charts.

As a map is a representation of some part of the surface of the earth delineated upon a plane, the earth being round, no part of the spherical surface of it can be accurately exhibited upon a plane, and, therefore, some have proposed the making of globular maps; for this purpose, a plate of brass might be hammered, or, at a less expence, a piece of paste-board might be formed into a segment of a sphere, and covered on its convex side with a map projected in the same, as the papers of the common globes are: a map made in this method would shew every thing in the same manner, as it would be seen upon a globe of the same diameter with the sphere upon the segment of which it was delineated: and, indeed,

deed, maps of this sort would be in effect segments of such a globe, but they are not in common use.

The ancients described all the parts of the known earth in one general map; in this view, one of them compares the shape of the earth to the leather of a sling, whose length exceeds its breadth: the length of the then known parts of the earth from east to west was considerably greater than from north to south; for which reason, the former of these was called the longitude, and the other the latitude.

The modern general maps are such as give us a view of an entire hemisphere, or half of the globe; and are projected upon the plane of some great circle, which terminates the projected hemisphere, and divides it from the other half of the globe, as the equator, or the meridian, or horizon of some place: from this circle the projection is denominated, and said to be equatorial, meridional, or horizontal.

Particular maps are such as exhibit to us less than an hemisphere; of this sort are the maps of the great parts, into which the earth is divided, as Europe, Asia, Africa, North-America, South-America; or maps of particular kingdoms, provinces, countries, or of lesser districts.

The projections of the circles in general maps are of two sorts, convex and concave: to understand which, we may imagine the globe, upon which the circles are delineated, to be of thin glass, and that half of it is viewed at a time; now we may be conceived to view this hemisphere either on the convex or concave side, and we may conceive it to be placed at different distances from the eye: from which diversity of our view, there will arise different projections, or pictures of it in a map. If the eye be supposed to be placed in some point of the surface of the sphere to view the concave of the opposite hemisphere, it is called the stereographic projection.

In this projection, the parts about the middle are a little contracted, so as to be too small for the extreme parts, the reason whereof will appear from hence (plate LXX. *fig. 1.*) that if a concave semicircle, with equal divisions, be viewed with the eye in the plane of it continued, at the distance of a semi-diameter from its center, the projection will be a straight line unequally divided, the parts appearing less the nearer to the center; consequently, if two semicircles cutting one another at right angles, drawn upon a concave hemisphere, and marked with equal divisions, be viewed in the manner now described, the projection of them will be straight lines unequally divided, as AC and BD (*fig. 2.*) the parts appearing less the nearer to the center. The stereographic projection is either equatorial, meridional, or horizontal.

The equatorial projection supposes the eye to be situated in one of the poles of the earth, and from thence to view the opposite concave hemisphere, with its circles, projected upon a plane of glass passing through the equator. Thus the eye is supposed

to be in the north pole, in order to view the southern hemisphere; and in the south pole to view the northern hemisphere. Thus *fig. 3.* is a map of the northern hemisphere upon that projection: here the meridians are all straight lines, and the parallels are complete circles.

The meridional projection supposes the eye to be in some point of the equator, and from thence to view the opposite concave hemisphere, projected upon a glass plane passing through some meridian, which a meridian drawn through the eye cuts at right angles. Thus *fig. 7.* is a map of the earth in two hemispheres, projected upon the plane of a meridian passing through one of the Canary-islands called Ferro. This meridian is made choice of, because, by making the projection thereon, one hemisphere contains Europe, Asia, and Africa; and the other North and South America. Here all the meridians are arches of circles, except that drawn through the eye, which is a straight line; and all the parallels are arches of circles, and the equator is a straight line.

M. de la Hire has invented another meridional projection, which comes the nearest of all to the nature of the globe, because the meridians are placed therein at equal distances, the parallels also are nearly equidistant, and consequently the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same as on the globe itself.

In the horizontal projection, the eye is supposed to be in that point of the surface of the globe, which is diametrically opposite to the place upon the horizon of which the projection is made, and from thence to view the opposite concave hemisphere, with its circles projected upon a glass plane, passing through that horizon. Thus, if we project any map of this sort upon the horizon of London, the eye is supposed to be in the place of the antipodes to London, and from thence to view the concave hemisphere. There is a great variety in this sort of projection; for if the place the horizon it is upon, be under the pole, the horizontal projection is the same with the equatorial already described. If the place be under the equator, it is the same with the meridional: if the place be in an oblique sphere, the projection will be different, according to the different latitude of the place; for it will approach nearer to an equatorial or meridional projection, according as the place is situated nearer to one of the poles, or to the equator.

*Fig. 4.* is a map projected upon the horizon of London, whose latitude is  $51^{\circ} 32'$ . The chief advantage of this kind of maps is this, that the place upon the horizon, on which the map is projected, is always in the center of it, and we may see the bearing of places from it.

A particular map is a part of a general one, and may be made upon the same principles, as by projecting

jecting a large hemisphere, and taking so much of it as the map is designed to contain. When we are to delineate a map of a smaller part of the earth, if it be near the equator, the meridians and parallels may be represented by equidistant right-lines. If at some distance from the equator, the parallels may be equidistant straight lines, and the meridians straight lines, a little converging towards the nearest pole; or the meridians may be straight lines, converging towards the nearest pole, and the parallels circular.

When we are to make a map of a very small district, as of a county or hundred, whatever part of the earth it be in, the meridians and parallels may be equidistant straight lines, drawn through every minute, &c. of longitude, according as the largeness of the map will allow. See PLOTTING and SURVEYING.

If the eye be supposed to view the hemisphere at an infinite distance, the projection of its circles, whether it be viewed on the convex or concave side, is called orthographic. In this projection, the parts about the middle are very well exhibited, but the extreme parts are very much contracted. See *Orthographic PROJECTION of the Sphere*.

*Fig. 5.* is a general map of the northern hemisphere projected orthographically upon the plane of the equator. Here the meridians are all straight lines, and the parallels are complete circles. *Fig. 6.* is a general map of an hemisphere, projected orthographically on the plane of the meridian. Here all the meridians are projected into semi-ellipses, except that which is perpendicular to the plane of projection, and which becomes a straight line thereon. This projection has one advantage not to be found in any other general map; namely, that the decrease of the parallels from the equator to the poles, appears therein in true proportion.

The great contraction of the extreme parts in the orthographic projection makes it so deficient in the second quality required in maps, that it is seldom used, except when the disk of the earth, in a solar eclipse, is to be exhibited.

The use of maps is obvious from their construction. The degrees of the meridians and parallels shew the longitude and latitude of places; their bearings from each other appear from inspection; and their distances may be measured by the divisions on the meridian, equator, &c.

**MAPLE**, *Acer*, in botany, a genus of trees producing male and hermaphrodite flowers, each having five ovate petals which spread over the cup. The stamina are eight short filaments, topped with simple antheræ, which are crowned with a cruciform pollen. The fruit consists of a number of capsules, which grow together at the base, and are compressed, roundish, and each terminated by a very large membranaceous ala. The seeds are single and roundish.

The common maple is so well known as to require no description. Most of the different species are propagated by sowing their seeds soon after they are ripe, which is in autumn, and the succeeding year they will be fit to be planted in rows about three feet asunder and two feet distance in the rows, where they may remain three or four years, when they will be large enough to be transplanted where they are intended to remain.

The timber of the common maple is far superior to beech for turners use, particularly dishes, cups, trenchers, &c. and when it abounds with knots (as it very often doth) it is highly esteemed by the joiners for inlaying, &c. and also, for the lightness of the wood, is often employed by those that make musical instruments; and, for the whiteness of it, was formerly in great request for tables, &c.

**MARANTA**, Indian arrow-root, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube of which is oblong, compressed, and crooked, and its limb cut in six segments; it hath one membranaceous filament, with a linear antheræ fastened to the border of the filament. The fruit is a roundish capsule, obscurely trigonal, containing a hard, rough, ovate seed.

**MARBLE**, *Marmor*, in natural history, a genus of fossils, being bright and beautiful stones, composed of small separate concretions, moderately hard, not giving fire with steel, fermenting with, and soluble in acid menstrua, and calcining in a slight fire.

The colours of marbles being a very obvious and striking character, they are arranged according to them, in the following divisions. 1. Of the white plain marbles there are two sorts; the Parian marble of the ancients, and statuary marble of the moderns, an extremely bright and elegant marble; and the Carrara marble; a very fine marble, more compact and close than the former, but less bright. 2. Of the plain yellowish marbles there is only one sort, which is a hard, pale yellow, and glossy marble, found in many parts of Italy. 3. Of the bluish and black marbles there are a great many species, as the Chian marble, Basaltes, &c. 4. Of the plain green marbles there is only one kind, the Lacedæmonian marble of the ancients. 5. The pale-coloured or whitish brown, commonly called Derby-marble. 6. The green marbles with shells. 7. The black Coralloide marble, with and without shells. 8. Of the white variegated marble there are a great many species, variegated with purple, brown, red, blue, &c. 9. Of the brown variegated marbles there are likewise several sorts, some with red veins, others with white, black, or brown veins. 10. Of the yellow veined and variegated marbles some are veined with purple, and others with blue. 11. Of the black variegated marbles, some are veined with white, and others with blue, yellow, red, &c. 12. The green variegated marbles

bles are likewise distinguished by the colour of their veins. 13. The grey spotted marbles are variegated, some with black and others with green spots. 14. The red variegated marble is the Brocatello of the Italians, with white and gold veins.

*Polishing of MARBLE.* is performed by first rubbing them well with a free-stone, or sand, till the strokes of the axe are worn off, then with pumice-stone, and afterwards with emery.

*Colouring of MARBLE.*—The colouring of marble is a nice art, and in order to succeed in it, the pieces of marble, on which the experiments are tried, must be well polished, and clear from the least spot or vein. The harder the marble is, the better it will bear the heat necessary in the operation; therefore, alabaster and the common soft white marble are very improper to perform these operations upon.

Heat is always necessary for the opening the pores of the marble, so as to render it fit to receive the colours; but the marble must never be made red hot, for then, the texture of the marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great; for, in this case, though the marble receive the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike even cold, but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menstruums used to strike in the colours, must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick-lime, and one part pot-ashes, is excellent for some colours; common ley of wood-ashes does very well for others: for some, spirit of wine is best; and, finally, for others, oily liquors, or common white-wine.

The colours which have been found to succeed best with the peculiar menstruums, are these: stone-blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call litmouse, dissolved in common ley of wood-ashes. An extract of saffron, and that colour made of buckthorn berries, and called by the painters sap-green, both succeed well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermillion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as does also a tincture of logwood, in the same spirit. Alkanet root gives a fine colour, but the only menstruum to be used for this is oil of turpentine; for neither spirit of wine, nor any lixivium, will do with it. There is another kind of sanguis draconis called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. *Philosophical Transactions.* N<sup>o</sup>. 268.

Besides these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood, of the purest kind, for a red; gamboge for a yellow; green-wax for a green; common brimstone, pitch, and turpentine, for a brown colour. The marble, for these experiments, must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal armoniac, vitriol, and verdigris, of each equal quantities; white vitriol succeeds best, and all must be thoroughly mixed in fine powder.

The staining of marble to all the degrees of red or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them, with the spirit of wine, in a glass mortar; but, for smaller attempts, no method is so good as the mixing a little of either of these powders with spirit of wine, in a silver spoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and, with a pencil dipped in this, the finest traces may be made on the marble, while cold, which, on the heating it afterwards, either on sand, or in a baker's oven, will all sink very deep, and will remain perfectly distinct in the stone. It is very easy to make the ground colour red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain, with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a slight tincture of it, without the assistance of heat to the marble, gives only a pale flesh colour, but the stronger tinctures give it yet deeper; to this the assistance of heat adds yet greatly; and, finally, the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to marble by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the Canary turnsol, a substance well known among the dyers: this needs only to be dissolved in water, and drawn on the place with a pencil; this penetrates very deep into the marble, and the colour may be increased by drawing the pencil, wetted afresh, several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may

may be kept in regular bounds, by circumscribing its lines with beds of wax, or any other such substance. It is to be observed, that this colour should be laid on cold, and no heat given afterwards to the marble; and one great advantage of this colour is, that it is therefore easily added to marble already stained with any other colours, and it is a very beautiful tinge, and lasts a long time. *Mem. Acad. Par. 1732.*

*Arundel* MARBLES, ancient marbles with a chronicle of the city of Athens inscribed on them, many years before our Saviour's birth; presented to the university of Oxford by Thomas earl of Arundel, whence the name.

MARBLING, the method of preparing and colouring the marbled paper.

There are several kinds of marbled marble paper; but the principal difference of them lies in the forms in which the colours are laid on the ground: some being disposed in whirls or circumvolutions; some in jagged lengths; and others in spots of a roundish or oval figure. The general manner of managing each kind is, nevertheless, the same; being the dipping the paper in a solution of gum tragacanth, or, as it is commonly called, gum-dragon; over which the colours, previously prepared with ox-gall and spirit of wine, are first spread.

The peculiar apparatus necessary for this purpose, is a trough for containing the gum-tragacanth, and the colours; a comb for disposing them in the figure usually chosen; and a burning stone for polishing the paper. The trough may be of any kind of wood; and must be somewhat larger than the sheets of paper, for marbling which it is to be employed; but the sides of it need only rise about two inches above the bottom; for by making it thus shallow, a less quantity of the solution of the gum will serve to fill it. The comb may be also of wood, and five inches in length; but should have brass teeth, which may be about two inches long, and placed at about a quarter of an inch distance from one another. The burnishing stone may be of jasper, or agate; but as those stones are very dear, when of sufficient largeness, marble or glass may be used, provided their surface be polished to a great degree of smoothness.

These implements being thus prepared, a solution of gum-tragacanth must be made, by putting a sufficient proportion of the gum, which should be white, and clear from all foulnesses, into clean water; and letting it remain there a day or two, frequently breaking the lumps and stirring it, till the whole shall appear dissolved, and equally mixed with the water. The consistence of the solution should be nearly that of strong gum-water, used in miniature painting; and if it appear thicker, water must be added, or if thinner, more of the gum. When the solution is thus brought to a due state, it must be passed through a linen cloth, and then

being put into the trough, it will be ready to receive the colours.

The colours employed for red are carmine, lake, rose-pink, and vermillion; but the two last are too hard and glaring, unless they are mixed with rose-pink, or lake, to bring them to a softer cast: and with respect to the carmine and lake, they are too dear for common purposes: — for yellow, Dutch pink and yellow oker may be employed: — for blue, Prussian blue and verditer may be used: — for green, verdigrise, a mixture of Dutch pink and Prussian blue, or verditer, in different proportions: — for orange, the orange-lake, or a mixture of vermillion, or red lead, with Dutch pink: — for purple, rose-pink and Prussian blue.

These several colours should be ground with spirit of wine till they be of a proper fineness; and then, at the time of using them, a little fish-gall, or in default of it, the gall of a beast should be added, by grinding them over again with it. The proper proportion of the gall must be found by trying them; for there must be just so much as will suffer the spots of colour, when sprinkled on the solution of the gum-tragacanth, to join together, without intermixing or running into each other.

When every thing is thus prepared, the solution of the gum-tragacanth must be poured into the trough; and the colours, being in a separate pot, with a pencil appropriated to each, must be sprinkled on the surface of the solution, by shaking the pencil, charged with its proper colour over it; and this must be done with the several kinds of colour desired, till the surface be wholly covered.

When the marbling is proposed to be in spots of a simple form, nothing more is necessary; but where the whirls or snail-shell figures are wanted, they must be made by means of a quill; which must be put among the spots to turn them about, till the effect be produced. The jagged lengths must be made by means of the comb above described, which must be passed through the colours from one end of the trough to the other; and will give them that appearance; but if they be desired to be pointed both ways, the comb must be again passed through the trough in a contrary direction; or if some of the whirls or snail-shell figures be required to be added, they may be yet made by the means before directed.

The paper should be previously prepared for receiving the colours, by dipping it over night in water; and laying the sheets on each other with a weight over them. The whole being thus ready, the paper must be held by two corners, and laid in the most gentle and even manner on the solution covered with the colours; and there softly pressed with the hand, that it may bear every where on the solution. After which it must be raised and taken off with the same care, and then hung to dry across a proper cord, subtended near at hand for that purpose:

Pose : and in that state it must continue, till it be perfectly dry. It then remains only to give the paper a proper polish ; in order to which it is first rubbed with a little sope ; and then must be thoroughly smoothed by the glass polishers, such as are used for linen, and called the calender glasses. After which it should be again rubbed by a burnisher of jasper or agate ; or, in default of them, of glass ground to the highest polish : for on the perfect polish of the paper depends in a great measure its beauty and value.

Gold or silver powders may be used, where desired, along with the colours ; and require only the same treatment as them, except that they must be first tempered with gum-water.

Marbling of books or paper is performed thus : dissolve four ounces of gum-arabic into two quarts of fair water ; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of intermixture upon the gum-water, which must be put into a trough, or some broad vessel ; then with a stick curl them, or draw them out in streaks, to as much variety as may be done. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly ; which done, take them off, and the plain impression of the colours in mixture will be upon the leaves ; doing as well the ends as the front of the book in the like manner.

Marbling a book on the covers is performed by forming clouds with aqua fortis, or spirit of vitriol mixed with ink, and afterwards glazing the covers. See the article BOOK-BINDING.

MARCASITES, *Marchasitæ*, in natural history, are defined to be compound inflammable metallic bodies, of a hard and solid substance, of an obscurely and irregularly foliaceous structure, of a bright glittering appearance, naturally constituting whole strata, though sometimes found in detached masses ; very freely giving fire with steel ; not fermenting with acid menstruums ; and when put into the fire, yielding a blue sulphureous flame, and afterwards calcining into a purple powder.

There are only three known species of this genus : 1. The silver-coloured marcasite, found in vast abundance in lead and tin-mines. 2. The gold-coloured marcasite. 3. The heavy pale-white marcasite.

Marcasites were at first supposed to be almost all pure gold or silver, according to their colour : but experience has shewn, that if they contain any metal at all, no method has hitherto been found of working them to advantage. In Germany, indeed, they extract sulphur and vitriol from the silver marcasite, which two substances are always contained in it ; and besides these, it has usually a quantity of arsenic. It has been recommended as

a styptic, after being calcined ; but as the arsenic may not be all carried off by that operation, its use as a medicine seems extremely dangerous.

MARCGRAVE, or MARGRAVE, a degree of honour in Germany answering to our marquis. See the article MARQUIS.

MARCGRAVIA, in botany, a genus of plants whose corolla is monopetalous and of a conico-ovate figure ; the stamina are numerous, and the fruit is a globose coriaceous berry, with a number of cells containing a great many small seeds wrapped in a soft pulp.

MARCH, in chronology, the third month in the year, consisting of thirty-one days. See the articles MONTH and YEAR.

MARCIONITES, Christian heretics in the second century, thus denominated from their leader Marcion, who maintained, that their were two principles or Gods, a good and a bad one. Origen affirms, that he held there was a God of the Jews, a God of the Christians, and a God of the Gentiles. It is said that he denied the resurrection of the body, condemned marriage, and taught that our Saviour, when he descended into hell, discharged Cain, the Sodomites, and other impious wretches, out of that place of torment. He rejected all the Old Testament, and received only part of St. Luke's Gospel, and ten of St. Paul's Epistles, in the New.

MARCOSIANS, a sect of Christian heretics in the second century, so called from their leader Marcus, who represented the supreme God as consisting not of a trinity, but a quaternity, viz. the ineffable, silence, the father, and truth. He held two principles, denied the reality of Christ's sufferings, and the resurrection of the body, and had the same fancies concerning the æons as Valentinus. See the articles ÆONS and VALENTINIANS.

The marcosians, it is said, made pretences to greater perfection than either St. Paul or St. Peter ; and being persuaded that nothing could hinder their salvation, freely indulged themselves in the practice of vice.

MARDIKERS, or TOPASSES, a mixed breed of Dutch, Portuguese, Indians, and other nations, incorporated with the Dutch at Batavia, in the East-Indies.

MARE, the female of the horse-kind. See the article HORSE.

Such mares as are designed for breeding, ought to be as free from defects as possible, and should, no more than the stallions, have either moon-eyes, watery-eyes, or bloodshot-eyes ; they should have no splint, spavin, or curb, nor any natural imperfection ; for the colts will take after them : but choice should be made of the best and ablest, the most high spirited, best coloured, and finest shaped ; and the natural defects that may be in the stallion, should

should be amended in the mare, as well as that which is amiss in the mare should be amended in the stallion.

As for her age, she may be covered when three years old; but the most convenient time is after four, when she will nourish her colt best; and tho' she may breed till she is thirteen, yet she is not fit for it when she is past ten, for the colt of an old mare is commonly heavy. Before a mare is covered, she should be in the house about six weeks, during which time she should be well fed with good hay and oats well sifted; and in order to render her conception the more certain, near a quart of blood may be taken from each side of her neck, about five or six days before covering. Another method to bring a mare in season and make her retain, is to give her, for the space of eight days before you bring her to the horse, about two quarts of hempseed in the morning, and as much at night; and if she refuses to eat it, to mingle it with a little bran or oats, or else to let her fast for a while: and if the stallion also eat of it, it will greatly contribute to generation.

Mares go with foal eleven months and as many days as they are years old; and therefore the properest time for covering them is in the beginning of June, that she may foal the May following, when there will be plenty of grass, which will afford the mares a great abundance of milk for nourishing their foals: but a mare should never be covered while she is bringing up her foal, because the foal to which she is giving suck, as well as that in her belly, will be prejudiced by it, and she herself sooner spent. After covering, let her, for three weeks or a month, have the same diet as before, and be kept clean in the stable till the middle of May, with her feet well pared and thin shod: take her in again about the latter end of September, if not before, and keep her to the end of her foaling. If she cannot readily bring forth, hold her nostrils so as to stop her taking wind; and if that will not do, dissolve madder, to the quantity of a walnut, in a pint of ale, and give it her warm. In case she cannot void her secundine, or after-burden, boil two or three handfuls of fennel in running-water, then put half a pint of that liquor into as much sack, or, for want thereof, into a pint of ale, with a fourth part of salad-oil, mixed together, and pour it luke-warm into her nostrils, holding them close for some time: otherwise give her green wheat, or rye, the last of which is best.

If the mare has but little milk, boil as much as you can get from her, with the leaves of lavender and spike, and bathe the udder with it warm, till the knobs and knots are dissolved. She should now drink only white water (which is bran put into water;) give her also sweet mashes: and a month after foaling let her have a mash with some brimstone or fayn in it.

MARIGOLD, in botany. See CALENDULA.

*African* MARIGOLD. See TAGETES.

*Corn* MARIGOLD. See CHRISANTHEMUM.

*Fig* MARIGOLD. See MESEMBRYANTHEMUM.

*French* MARIGOLD. See TAGETES.

*Marsh* MARIGOLD. See CALTHA.

MARJORAM, in botany. See MAJORANA and ORIGANUM.

MARITIME, something relating to, or bounded by the sea: thus, a maritime province, or country, is one bounded by the sea; and a maritime kingdom, or state, is one that makes a considerable figure, or is very powerful, at sea.

MARK, in commerce, a certain note which a merchant puts upon his goods, or upon the cask, hoghead, &c. that contains them, in order to distinguish them from others.

*St. MARK the Evangelist's Day*, a festival of the Christian church, observed April 25.

*St. MARK's Gospel*, a canonical book of the New Testament, being one of the four Gospels.

St. Mark wrote his Gospel at Rome, where he accompanied St. Peter, in the year of Christ 44. Tertullian and others pretend, that St. Mark was no more than an amanuensis to St. Peter, who dictated this Gospel to him; others affirm that he wrote it after St. Peter's death. Nor are the learned less divided as to the language this Gospel was wrote in; some affirming it was composed in Greek, others in Latin. Several of the ancient heretics received only the Gospel of St. Mark; others among the Catholics, rejected the twelve last verses of this Gospel. The Gospel of St. Mark is properly an abridgment of that of St. Matthew.

MARK, or MARC, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into eight ounces, or sixty-four drams, or one hundred and ninety-two deniers, or penny-weights, or one hundred and sixty esterlines, or three hundred mailles, or six hundred and forty felins, or four thousand six hundred and eight grains. In Holland, the mark-weight is also called troy-weight, and is equal to that of France. When gold and silver is sold by the mark, it is divided into twenty-four carats. See the article CARRACT.

MARK, is also used among us for a money of account, and in some other countries for a coin.

The English mark is two-thirds of a pound sterling, or thirteen shillings and four-pence; and the Scotch mark is of equal value in Scotch money of account. The mark-lubs, or Lubec-mark, used at Hamburg, is also a money of account, equal to one-third of the rix-dollar, or to the French livre; each mark is divided into sixteen sols-lubs. Mark-lubs is also a Danish coin equal to sixteen sols-lubs. Mark is also a copper and silver coin in Sweden. See the article EXCHANGE.

MARKET, a public place in a city or town in which

which live cattle, provisions, or other goods, are set to sale; and also a privilege, either by grant or prescription, by which a town is enabled to keep a market.

**MARLE**, *Marga*, a kind of dry, soft, fossil earth, used for manuring land.

The word is derived from the old Celtic *marga*, mentioned by Pliny, and afterwards called *margilla*.

The principal sorts of marle are the white and red. Too much of it thrown on the ground is found to burn it. Marle is burnt like other stone for making of lime.

It is a very material circumstance in the marling of land, to find out how much the land requires of this manure; and, till experience has thoroughly shewn this, it is better to err in laying on too little than too much; because the latter is a fault not to be remedied. It is to be observed also, that marle never makes so great an improvement on land the first year, as it does afterwards.

*Dice MARLE*, in husbandry, a name given by the people of Staffordshire to a reddish marle, that breaks into small square pieces like dice, or else into thin flakes, in the manner of lead ore, and looks smooth on the surface.

**MARLINE**, amongst seamen, a small cord or line, used to fasten the strops of blocks, &c. See **BLOCK**.

**MARLINE-SPIKE**, a kind of iron pin, with a large head, and tapering at the other end to a point. It is employed to penetrate the twists or strands of rope in the time of splicing, &c. which is joining the end of one rope to another. See the article **SPLICE**.

The marline-spike is also used for many other purposes of a similar nature.

**MARMALADE**, a confection of plums, apricots, quinces, &c. boiled with sugar to a proper consistence.

**MARMOR**, marble. See **MARBLE**.

**MARMOTTE**, in zoology, the largest animal of the mus or rat kind, with a long naked tail and tawney body; it is near as big as a hare, and breeds only on the tops of mountains in Switzerland. Its feet are somewhat like those of a bear.

**MARONITES**, in church-history, a sect of Christians near mount Libanus in Syria, who are in communion with the church of Rome, and have their patriarch, archbishops, bishops, &c.

**MARQUE**, or *Letters of MARQUE*, in military affairs, are letters of reprisal, granting the subjects of one prince or state liberty to make reprisals on those of another.

Letters of marque, among us, are extraordinary commissions granted by authority, for reparation to merchants, taken by strangers at sea; and reprisals is only the retaking or taking of one thing for another.

**MARQUETRY**, or **INLAID-WORK**, is a curious work composed of several fine pieces of wood, of various colours, fastened in thin slices on a ground,

and sometimes enriched with other matters, as silver, brass, tortoise-shell, and ivory; with these assistances the art is now capable of imitating any thing; whence it is by some called the art of painting in wood.

The ground on which the pieces are to be arranged and glued, is usually of well-dried oak or deal, and is composed of several pieces glued together, to prevent its warping. The wood to be used in marquetry is reduced into leaves of the thickness of a line, or the twelfth part of an inch, and is either of its natural colour, or stained, or made black to form the shades by other methods: this some perform by putting it in sand heated very hot over the fire; others, by steeping it in lime-water and sublimate; and others, in oil of sulphur. The wood being of the proper colours, the contours of the pieces are formed according to the parts of the design they are to represent: this is the most difficult part of marquetry, and that which requires the most patience and attention.

The leaves to be formed, of which there are frequently three, four, or more joined together, are, after they have been glued on the outermost part of the design, whose profile they are to follow, put within the chaps of the vice; then the workman pressing the treddle, and thus holding fast the piece, with his saw runs over all the out-lines of his design. By thus joining or forming three or four pieces together, not only time is saved, but also the matter is the better enabled to sustain the efforts of the saw, which, how fine soever it may be, and how slightly soever it may be conducted by the workman, except this precaution were taken, would be apt to raise splinters, and ruin the beauty of the work. All the pieces having been thus formed by the saw, and marked, in order to their being known again, each is vaneered, or fastened in its place, on the common ground, with the best English glue; and this being done, the whole is set in a press to dry, planed over, and polished with the skin of the sea-dog, wax, and shave-grass, as in simple vaneering, and the fine branches and more delicate parts of the figures are touched up and finished with a graver.

**MARQUIS**, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

Marquisses were not known in England till king Richard II. in the year 1337, created his great favourite, Robert Vere, the earl of Oxford, marquis of Dublin; since which time there have been many creations of this sort, though at present there is but one English and two Scotch marquisses. The manner of creating a marquis differs in nothing from that of a duke, except the difference of the titles, and the marquis's being conducted by a marquis and an earl, while a duke is led by a duke and a marquis;

quis; he is also girt with a sword, has a gold verge put into his hand, and his robe or mantle is the same as those of a duke, with only this difference, that a duke's mantle has four guards of ermine, and a marquis's only three and a half. The title given him, in the style of the heralds, is most noble and potent prince. His cap is the same as a duke's, and the difference between their coronets consists in the duke's being adorned with only flowers or leaves, while the marquis's has flowers and pyramids with pearls on them, intermixed, to shew that he is a degree between a duke and an earl.

**MARRIAGE**, a contract both civil and religious, between a man and a woman, by which they engage to live together in mutual love and friendship, for the ends of procreation, &c.

**MARROW**, *Medulla*, in anatomy, has various significations: the white substance of the brain, in contradistinction from the cortical part, is called the spinal marrow; but, properly, marrow denotes that soft oleaginous substance contained in the cavity of the bones.

Every bone in the body of any considerable thickness, has either a large cavity, or is full of little cells; in both the one and the other is marrow contained in proper vesicles that open into one another.

In the larger bones this fine oil, by the gentle heat of the body, enters some narrow passages, which lead to certain fine canals excavated in the substance of the bone; and from these other cross passages, not directly opposite to the former, carry the marrow still farther into more longitudinal canals placed nearer the surface of the bone. All this contrivance is, that the marrow may supple the fibres of the bones, and render them less apt to break.

By latter observations, blood-vessels have been found in the bones, so that they are nourished in the same manner as the other parts of the body. Besides we find that many bones grow, and yet have no marrow in them, as the horns of deer, lobsters claws, &c.

All marrows are mollifying, rarefying, give relief by friction under lassitudes and incarnate ulcers.

**MARRUBIUM**, hore-hound, in botany, a genus of plants, whose flower is monopetalous and labiated, the upper lip of which is erect, semibifid, and acute, and the under lip reflexed and cut into three segments, the seeds are four and contained in the cup. The common hore-hound, has a woody fibrous roots from which arise several hairy square stalks which are furnished with hoary roundish leaves, wrinkled and crenated on their edges; the flowers proceed in whorles from the joints of the stalks in June, and are of a white colour, the whole plant has a strong disagreeable smell, and grows wild in

many parts of England: it is aperient and powerfully resolves viscid humours, and by some is accounted a specific in moist asthma's, and in all diseases of the breast and lungs: the dose in infusion is from half a handful, to a handful, the dried leaves may be given to a dram or two.

**MARS**, in astronomy, one of the superior planets, moving round the sun in an orbit between those of the earth and Jupiter. See the article **PLANET**.

For the diameter of this planet, and its mean distance from the sun, see the articles **DIAMETER** and **DISTANCE**.

The character of this planet is  $\delta$ , the eccentricity of its orbit 141, supposing the distance of the earth from the sun 1000 equal parts; the inclination of its orbit to that of the earth is  $1^{\circ} 51'$ ; the periodical time in which it performs its revolution round the sun, is 686 days, 23 hours,  $27' 30''$ ; its revolution round its own axis 24 hours  $40'$ ; and its parallax,  $30''$ . See the articles **CHARACTER**, **EXCENTRICITY**, &c.

In the achronical rising of this planet, that is, when it is in opposition to the sun, it is found twice as near the earth as the sun, which is a phenomenon that has greatly discredited the Ptolemaic hypothesis. This planet, as well as the rest, borrows its light from the sun and has its increase and decrease of light like the moon; and it may be seen almost bisected when in its quadratures with the sun, or its perigæon; but is never corniculated or falcated, as the inferior planets.

Dr. Hook, in 1665, observed several spots in this planet, which having a motion, he concluded the planet to have a turbinated motion round its center. In 1666, M. Cassini observed several spots in the two hemispheres of Mars, which by continuing his different observations very diligently, he found to move by little and little from east to west, and to return in the space of 24 hours  $40'$  to their former situation. Whence both the motion and period or natural day of that planet were determined. See the article **MACULÆ**.

Mars always appears with a ruddy troubled light, whence we conclude that it is encompassed with a thick cloudy atmosphere, which by disturbing the rays of light in their passage and re-passage through it, occasion that appearance. Besides the ruddy colour of Mars, we have another argument of his being encompassed with an atmosphere, and it is this, that when any of the fixed stars are seen near his body, they appear extremely obscured and almost extinct; and if this be the case, a spectator in Mars would scarce ever see Mercury, unless perhaps in the sun at the time of conjunction, when Mercury passes over his disk, as he sometimes appears to us in form of a spot. An eye in Mars will

see Venus at about the same distance from the sun as Mercury appears to us, and the earth about the same distance from the sun that Venus appears to us; and when the earth is found in conjunction with and very near the sun, the eye in Mars will see the earth horned or falcated, and its attendant, the moon, of the same figure, and at its utmost distance from the earth not above fifteen minutes of a degree: and as this planet's distance from the sun is to the distance of the earth and sun as  $1\frac{1}{2}$  to 1; therefore a spectator in Mars would see the sun's diameter less by one third than it appears to us, and consequently the degree of light and heat which Mars receives from the sun, is less by one third than that received by the earth; this proportion will however, admit of a sensible variation, on account of the great excentricity of this planet.

Though the period or year of this planet as has been already observed, is nearly twice as long as ours, and his natural day, or the time in which the sun appears above his horizon, setting aside the consideration of twilight, is almost every where equal to his night; yet it appears that in one and the same place, on his surface, there will be but very little variety of seasons, or scarce any difference of summer and winter: and the reason is that the axis of his diurnal rotation is nearly at right angles with the plane of his orbit. It will be found notwithstanding, that places situated in different latitudes, that is, at different distances from his equator, will have very different degrees of heat, on account of the different inclination of the sun's rays to the horizon, as it is with us when the sun is in the equinoxes.

From this consideration Dr. Gregory endeavours to account for the appearance of the fasciæ in Mars, which are certain swaths or fillets seen in this planet, and posited parallel to his equator; for as among us, the same climate has at different seasons very unequal degrees of heat, but as in Mars it is otherwise, the same parallel having always a pretty equal degree of heat, it follows that these spots may probably be formed in Mars, or in his atmosphere, as snow and clouds are in ours, viz. by the constant different intentions of heat and cold in the different parallels, and so come to be extended in circles or belts parallel to his equator, or the circle of his diurnal motion. And this same principle may, perhaps solve the phenomenon of Jupiter's belts, that planet, like Mars, having a perpetual equinox. See the article JUPITER.

MARS, among chemists, denotes iron, as being supposed to be under the influence of that planet. See the article IRON.

*Crocus of MARS.* See CROCUS MARTIS.

MARINE implies in general the whole navy of a kingdom or state, comprehending all the royal dock-yards, and the officers, artificers, seamen, fol-

diers, &c. employed therein, as well as the shipping employed by the merchants for military or commercial purposes, together with whatever relates to navigation, ship-building, sailors, and marines.

The history of the marine affairs of any one state is a very comprehensive subject, much more than of all nations. Those who would be informed of the maritime affairs of Great Britain, and the figure it has made at sea in all ages, may find abundance of curious matter in Selden's *Mare Clausum*, and from his time to ours, we may trace a series of facts in Lediard's and Burchet's Naval History; but above all, in the Lives of the Admirals, by the accurate and judicious Dr. Campbell.

Not only the preservation of that share of commerce we at present possess, but its future advancement, and even the very being of Britain, as an independent empire, and a free people, depend no less on the good condition and the wise regulation of our affairs of the marine, than on the superiority of its naval power. The Delphian oracle being consulted by the Athenians on the formidable armament and innumerable forces of Xerxes, returned for answer, "that they must seek their safety in wooden walls." To which we may affirm, that whenever this nation in particular has recourse to her floating bulwarks for her security and defence, she will find strength, wealth, and glory, to be the happy and infallible consequence.

That the legislature has ever been attentive to this great and important object will appear from the following account of the laws that have been enacted relating to the affairs of the British marine.

So early as 5 Rich. II. c. 3. it was enacted, that none of the king's subjects should bring in or carry out any merchandize, but in English ships, on pain of forfeiting all the merchandize otherwise conveyed, or the value thereof; but 6 Rich. II. ordains, that the above statute shall only take place where able ships belonging to the king's subject are to be found; for where they are not to be had, the merchants are allowed to hire other ships. By 4 Hen. VII. c. 10. it was enacted, that no Gascoign or Guieune-wines, &c. should be imported into this realm but in English vessels: and that none should freight any merchandize in any stranger's ship, if he could have sufficient freight in a denizen's ship, under the penalty of forfeiting all merchandize not thus shipped, to be divided between the king and the seizer: but this act, so far as it related to the above wines, was repealed by statute 32 Hen. VIII. c. 14. and a rate was ordered of what should be paid for the freight of the several sorts of merchandize in ships from the port of London to other places, and from thence to London. By 1 Eliz. c. 13. it was enacted, that if the owner of any merchandize should in the time of peace, embark or unload any part thereof, (masts, pitch, tar and corn, only excepted)

out of, or into any foreign ship, he should pay custom as an alien.

By the act of navigation, 12 Car. II. c. 18. it is enacted, that no goods shall be imported into, or exported out of, any territories belonging to, or that may hereafter belong to his majesty, his heirs and successors, in Asia, Africa, or America, in any other ships besides such as belong to the people of England, Ireland, Wales, or the town of Berwick upon Tweed, and whereof the master and three-fourths of the mariners are English, on pain of forfeiting both the ship and lading, one third part to the king, another to the governor of the country where such default shall be, if seized there, otherwise that third also to the king, and the other third to him that will seize or sue for the same. And commanders at sea, having the king's commission, are to bring in as prize all such ships, and on their being condemned, one moiety is to be for the use of such commanders and their companies, and the other moiety to the king. No goods of the growth or manufacture of Muscovy, or of the produce of the Turkish empire, shall be imported into England, Ireland, &c. in any ship or vessel not English built, or not belonging to the people of England, Ireland, &c. and navigated as aforesaid; except vessels built at the place from whence the goods came, or of such port where they can only be, and usually are shipped, on pain of forfeiting the ship and goods; and all wines of the growth of France and Germany, and divers goods and merchandize from Spain, Portugal, Russia, &c. which shall be imported into the places aforesaid, in any other ship than what doth belong to England, Ireland, &c. and are navigated as aforesaid, shall be deemed aliens goods, and pay accordingly. And no foreign built vessel shall pass as a ship belonging to England, Ireland, Wales, &c. till the owner makes it appear to the chief officer of the customs, in the port next to the place of his abode, that he is not an alien, and takes an oath that it was *bona fide* bought of such persons, expressing the sum given, and the time and place when and where, &c. and that no foreigner has a share in it. Also none shall load in any bottom, if strangers or owners, part-owners, or master, and of which three-fourths of the mariners at least are not English, any goods whatsoever from one port or creek of England, Ireland, Wales, Guernsey, Jersey, or the town of Berwick, to another port of the same, on pain of forfeiting such goods and vessel.

The 22 and 23 Car. II. c. 11. ordains, that where any goods shall be laden on board only English ship of the burden of two hundred tons, or upwards, and mounted with sixteen guns or more, if the master yields up such ship or goods to any Turkish vessel, or any pirate, without fighting, upon proof thereof in the admiralty, he shall be incapable of taking charge of any English vessel: and

masters of English ships, though not of that burden, nor mounted as aforesaid, that shall yield without fighting to a Turkish ship or pirate, that has not at least double the number of guns, shall be liable to the penalties of this act. If any inferior officers or mariners of a ship, shall refuse to fight when commanded, or utter words to discourage others, they shall lose all their wages due, and be imprisoned not exceeding six months; and mariners laying violent hands on their commanders, to hinder them from fighting in defence of their ships, shall suffer death as felons. When any English ship shall have been defended by fight, and brought to her port, in which fighting any of her men have been wounded or slain, the judge of the admiralty, or his surrogate, &c. where she shall arrive, upon the petition of the master and seamen, may call so many as he shall be informed are the adventurers and owners, and by advising with them, levy upon the respective owners such sums as he himself, and the major part of them present, shall judge reasonable, not exceeding two per cent of the ship and goods; which money shall be distributed among the master, officers, and seamen, or the widows and children of the slain, according to the direction of the judge, with the approbation of three or more of the adventurers. By 5th and 6th of William and Mary, c. 24. every person who shall build, or cause to be built, any ship of three decks, containing 450 tons, and mounted with thirty-two pieces of ordnance, having ammunition, &c. proportionable, shall for the first three voyages which the said ship shall make to any foreign parts, receive a tenth of the customs called the subsidy of tonnage and poundage, payable for merchandize exported and imported in such ships; but if after the end of the three first voyages, ships so built, shall be altered so as to become less defensible than they were at first, then they shall be forfeited and lost.

By 2 Ann. c. 9. owners of ships might navigate during the war with France, with masters, and only one half of the mariners English: and by 3 and 4 Ann. c. 13. any ships might be navigated by foreign seamen; and foreigners serving on board any English ship for two years, were to be deemed natural-born subjects, &c.

By 4 Geo. I. c. 12. and 11 Geo. I. c. 29. if any officer or mariner belonging to any ship or vessel, shall wilfully cast away, burn, or destroy the ship to which he belongeth, or in any-wise direct or procure the same to be done, with intent to prejudice a person that shall have granted any insurance thereon, or any merchant who shall load goods therein, or any owner of such vessel, the persons offending shall on conviction be adjudged guilty of felony without benefit of clergy.

The 5th of Geo. II. c. 20. enacts, that no commander of any ship outward-bound shall receive on board any gun-powder, either as merchandize or stores

stores for the voyage, except for his majesty's service, before such ship shall be at Blackwall, in the river Thames; and all masters of ships coming into the river, shall put on shore all powder either before the arrival of their ships at the said place, or within twenty-four hours after they come to anchor there, upon pain of forfeiting 5*l.* for every 50 pounds weight of gun-powder on board, and in like proportion for a less quantity. And no guns shall be kept loaded with shot in merchant ships between London-bridge and Blackwall, or fired before the rising, or after the setting of the sun, under the penalty of 5*l.* and for every gun so fired, 10*s.* And if any pitch, tar, rosin, or other combustible matter shall be heated or melted by fire in any ships, every person so offending, shall, for every offence, forfeit 5*l.* And ships are liable to be searched by an elder brother, appointed by the master, wardens, and assistants of the Trinity-house at Deptford. In case any ship shall be moored in the mouth or at any other part of St. Saviour's dock, except such ships as shall be loading or delivering their cargoes, and others, not exceeding two at a time, that shall lie at Shipwright-yard, at the north-west corner of the said dock, during the time they shall be repairing, the master of such ship shall forfeit 20*s.* for every day she shall continue to be laid up and moored.

By 6 Geo. II. c. 29. masters of ships lying in the river Thames who have occasion for ballast, shall pay 1*s.* per ton colliers, other ships 1*s.* 3*d.* and foreign ships 1*s.* 7*d.* per ton, to the corporation of the Trinity-house at Deptford; who shall pay ballast-men 9*d.* a ton, for raising and carrying it, &c. and it shall be lawful for any master of a ship to appoint two persons to go on board any lighter bringing ballast to such ships, to inspect the marks thereof; and every ballast-man shall immediately before the delivery of ballast to any ship, trim such lighter, so as to make it swim at equal marks at the stem and stern, and pump all the water out, &c. and the master, wardens, and assistants of the Trinity-house, are to make good to the master, the quantity or value of the ballast which shall be found deficient, or forfeit 50*l.* one moiety to the poor, and the other to the person suing for it. The 7th of Geo. II. c. 15. ordains, that no owners of ships shall be liable to any loss by reason of embezzlement by the master or mariners, of any goods shipped on board, or for any act done by them, without the privity or knowledge of such owners, further than the value of the ship, and amount of the freight during the voyage, in which such embezzlement of the master or mariners shall be committed; and if several persons shall suffer damage by the means aforesaid, and the value of the ship and cargo should not be sufficient to make compensation, then the freighters shall receive satisfaction in average, in proportion to their respective losses, to

be ascertained on a bill in equity, exhibited for a discovery thereof, and of the value of such ship and freight. But nothing in this act shall discharge any remedy, which any person may have against the master and mariners, in respect of an embezzlement. See the articles FREIGHT, INSURANCE, &c.

MARINES, or MARINE FORCES, a body of soldiers raised for the sea-service, and trained to fight either in a naval engagement, or in an action ashore.

The great service of this useful corps was manifested frequently in the course of the late war, particularly at the siege of Belleisle, where they acquired a great character, although lately raised, and hardly exercised in military discipline. At sea they are incorporated with the ship's crew, of which they make a part, and many of them learn in a short time to be excellent seamen, to which their officers are ordered by the admiralty not to discourage them, although no sea-officer is to order them to go aloft against their inclination. In a sea-fight their small arms are of very great advantage in scouring the decks of the enemy; and when they have been long enough at sea to stand firm when the ship rocks, they must be infinitely preferable to seamen if the enemy attempts to board, by raising a battalion with their fixed bayonets to oppose him. See the article BOARDING.

The marine forces of Great-Britain in the time of peace are stationed in three divisions; one of which is quartered at Chatham, one at Portsmouth, and another at Plymouth. By a late regulation they are ordered to do duty at the several dock-yards of those ports, to prevent embezzlement of the king's stores, for which a captain's guard mounts every day; which certainly requires great vigilance, as so many abuses of this kind have been committed, that many of the inhabitants, who have been long used to an infamous traffic of this kind, expect these conveyances at certain periods, as their due, and of course resent this regulation in the highest degree as an infringement of their liberty as Englishmen.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as earl marshal, knight-marshal, or marshal of the king's house, &c.

MARSHAL, or MARESCHAL, *of France*, an officer of the greatest dignity in the French armies. When two or more mareschals are in the army, the eldest commands.

MARSHALLING a coat, in heraldry, is the disposal of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

MARSHMALLOW, in botany. See the article ALTHÆA.

MARSHY LANDS, those liable to be over flowed

ed by the sea, or large rivers, for the draining of which, see the articles DITCH, DRAIN, &c.

MARSILEA, in botany, a genus of plants of the fern kind; the flowers are male and female, but without cup or corolla; the male flower consists of four subulated antheræ, and placed on a hemispherical-convex body; the female flower consists of a roundish pericarpium with four cells, in each of which are contained several roundish seeds. Under this genus is comprehended the *salvinia* of Micheli.

MARSUPIALIS MUSCULUS, in anatomy, a muscle otherwise called the internal obturator. See OBTURATOR.

MARTIAL, among physicians, an appellation given to the preparations of iron.

MARTIAL LAW, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it: for though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

MARTIN, *Martes*, in zoology, a species of mustela, of a blackish brown colour, and with a pale throat: it is about the size of the common cat, but more slender. See MUSTELA.

MARTIN is also the name of a bird of the hirundo kind, of a black colour, and with the throat white.

MARTINGALE, in the manege, a thong of leather fastened to one end of the girths under the belly of a horse, and at the other end to the muf-roll, to keep him from rearing.

MARTLETS, in heraldry, little birds represented without feet, and used as a difference or mark of distinction for younger brothers, to put them in mind that they are to trust to the wings of virtue and merit, in order to raise themselves, and not to their feet, they having little land to set their feet on.

MARTYNIA, in botany, a genus of plants, whose flower is monopetalous and campanulated, gibbous at the base, and containing a honey juice: the fruit is an oblong gibbous capsule, dividing into two parts, including a ligneous wrinkled nut, terminating with two incurved horns, and containing four cells, each including an oblong seed.

MARTYR, in the Christian sense of the word, is one who lays down his life for the Gospel, or suffers death for the sake of his religion.

The festivals of the martyrs are of very ancient date in the Christian church, and may be carried back at least till the time of Polycarp, who suffered martyrdom about the year of Christ 168. On these days the Christians met at the graves of the martyrs, and offered prayers and thanksgivings to God for the examples they had afforded them; they celebrated the eucharist, and gave alms to the poor; which, together with a panegyric oration or sermon, and

reading the acts of the martyrs, were the spiritual exercises of these anniversaries.

MARTYROLOGY, in the church of Rome, is a catalogue or list of martyrs, including the history of their lives and sufferings for the sake of their religion.

MARVEL of Peru, in botany. See the article MIRABILIS.

MARUM, Syrian-mastic, in botany, a low shrubby plant, with leaves like those of thyme, but hoary; the flowers are of the labiated kind, and grow in whorled spikes; they appear in July and August.

Marum is propagated by slips or cuttings in the summer months, and afterwards transplanted in a warm dry situation; but the greatest difficulty is to preserve it from cats, who are so fond of it, that they will come a considerable distance and destroy it; but if there are great quantities of it together, they will but little damage it.

Marum is reputed cephalic, and good in all disorders of the nerves, and also for stopping hæmorrhages.

MARY MAGDALEN'S DAY, a festival of the Romish church, observed on the twenty-second of July.

MASCULINE, or MASCULINE-GENDER, among grammarians, that belonging to the male. See GENDER.

MASON, a person employed under the direction of an architect, in the raising of a stone building.

The chief business of a mason is to make the mortar, raise the walls from the foundation to the top, with the necessary retreats and perpendiculars; to form the vaults, and employ the stones as delivered to him. When the stones are large, the business of hewing or cutting them belongs to the stone-cutters, though these are frequently confounded with masons: the ornaments of sculpture are performed by carvers in stone or sculptors. The tools or implements principally used by them are the square, level, plumb-line, bevel, compass, hammer, chissel, mallet, saw, trowel, &c. See the articles SQUARE, &c.

MASONRY, in general, a branch of architecture, consisting in the art of hewing or squaring stones, and cutting them level or perpendicular, for the uses of building; but in a more limited sense, masonry is the art of assembling and joining stones together with mortar.

Hence arises as many different kinds of masonry, as there are different forms and manners for laying or joining stones. Vitruvius mentions several kinds of masonry used among the ancients, three of hewed stones, viz. that in form of a net, that in binding, and that called the Greek masonry; and three of unhewed stones, viz. that of an equal course, that

of an unequal course, and that filled up in the middle; and the seventh was a composition of all the rest, each in their order.

Net-masonry, called by Vitruvius *reticulatum*, from its resemblance to the meshes of a net, consists of stones squared in their courses, and so disposed as that their joints go obliquely; and their diagonals are the one perpendicular, and the other level. This is the most agreeable masonry to the eye, but it is very apt to crack. See plate LXIX. *fig. 8.*

Bound-masonry, that in which the stones were placed one over another, like tiles; the joints of their beds being level, and the mounters perpendicular, so that the joint that mounts and separates two stones, always falls directly over the middle of the stone below. This is less beautiful than the network; but it is more solid and durable. See *fig. 9.*

Greek-masonry, according to Vitruvius, is that where after we have laid two stones, each of which makes a course, another is laid at the end, which makes two courses, and the same order is observed throughout the building; this may be called double binding, in regard the binding is not only of stones of the same course with one another, but likewise of one course with another course. See *fig. 10.*

Masonry by equal courses, called by the ancients *isodomum*, differs in nothing from the bound-masonry, but only in this, that its stones are not hewn. See *fig. 11.*

Masonry by unequal courses, called *pseudisodomum*, is also made of unhewn stones, and laid in bound-work; but then they are not of the same thickness, nor is there any equality observed, excepting in the several courses; the courses themselves being unequal to each other. See *fig. 12.*

Masonry filled up in the middle, called by the ancients *empletion*, is likewise made of unhewn stones, and by courses; but the stones are only set in order as to the courses.

*Fig. 13.* A, the courses; B, the parts filled up; C, a coat of plaster.

Compound masonry is of Vitruvius's proposing, so called as being formed of all the rest. In this, the courses are of hewn stones; and the middle being left void, is filled up with mortar and pebbles thrown in together: after this, the stones of one course are bound to those of another course, with cramp-irons fastened with melted lead.

*Fig. 14.* E, the stones cramped; F, the cramps; G, the middle part filled up.

*Fig. 15.* represents another sort of compound masonry, the middle of which is stone, and the edges boards.

All the kinds of masonry now in use may be reduced to these five, viz. bound masonry; that of brick-work, where the bodies and projectures of the stones inclose square spaces or pannels, &c. set with bricks; that de moilon, or small work, where the courses are equal, well squared, and their edges or

beds rusticated; that where the courses are unequal; and that filled up in the middle with little stones and mortar.

MASQUE, or MASK, a cover for the face, with suitable apertures for the eyes and mouth.

MASQUES, in architecture, denotes certain grotesque faces, used to fill vacant places, as friezes, pannels of doors, keys of arches, &c.

MASQUERADE, an assembly of persons masked, and dressed in peculiar habits, meeting to dance and divert themselves.

MASS, *Missa*, in the church of Rome, the office or prayers used at the celebration of the eucharist; or in other words, consecrating the bread and wine into the body and blood of Christ, and offering them so transubstantiated, as an expiatory sacrifice for the quick and the dead. As the mass is in general believed to be a representation of the passion of our blessed Saviour, so every action of the priest, and every particular part of the service, is supposed to allude to the particular circumstance of his passion and death.

MASSALIANS, a set of enthusiasts who sprang up about the year 361, in the reign of the emperor Constantius, who maintained that men have two souls, a celestial, and a diabolical, and that the latter is driven out by prayer. They pretended to prophecy, and affirmed that they could see the Trinity with their corporeal eyes; and believed that the Holy Ghost descended visibly upon them, especially at the time of their ordination, when they trod the devil under foot, and danced upon him.

MASSETER, in anatomy, a muscle which has its origin in the lower and interior part of the jugum, and its end at the external superficies of the angle of the jaw. The ductus Stenonianus, or salivary duct of Steno, passes over this muscle.

MASSIVE, among builders, an epithet given to whatever is too heavy and solid: thus a massive column is one too short and thick for the order whose capital it bears; and a massive wall is one whose openings or lights are too small in proportion.

MASSORA, in matters of literature, a critical work, containing remarks on the verses, words, letters, and vowel-points of the Hebrew text of the Bible; a work more laborious than useful, such poor observations being beneath the notice of men of learning.

MAST, in ship building, a large strong post, or pole, of timber, standing erect in a ship to carry sail, whereby she is enabled to make her progress through the sea.

Among the ancient Grecians every ship had several masts: we are nevertheless informed by Aristotle, that at first there was only one mast, which being fixed in the middle of the ship, the hole into which the foot of it was inserted, *μεσοδμη*; in Latin, *modius*; and in English, the *step*. The parts

# M A S

of the mast were these: *πτερνα*, or the foot; *λινας*, or, according to *Athenæas*, *λινος*, or *τραχηλος*, to which the sail was fixed; *καρχησιον*, the pulley by which the ropes were turned round; *θωρακιον*, built in the manner of a turret, for soldiers to stand upon and cast their darts; above this was a piece of wood, called *ικριον*, the extremity of which was termed *ηλακκτη*, on which hung a ribband, called, from its continual motion, *επισειων*, turning round with the wind; this is termed in English, the *vane*.

With regard to the moderns, the masts of their ships generally consist of three pieces, joined together lengthwise, viz. the lower-mast, the top-mast, and the top-gallant-mast. The top-mast stands at the head of the lower-mast, and the top-gallant-mast at the head of the top-mast in the same manner, and either of the two latter can be occasionally taken down; but the lower-mast as it is settled on the keel of the ship, can only be removed by hoisting it out or cutting it away.

A little below the head of the lower-mast is fixed the frame of the top, which rests upon the hounds of the mast; through this frame the top-mast is hoisted, after which, the head of it passes through the cap, which is a block of wood with two holes in it, one of which rests on the head of the lower-mast, and the other serves as above to keep the top-mast steady. When the top-mast is thus hoisted up to its utmost extent, and kept steady above by the cap, and below by the top-frame, a large bar of wood or iron is thrust through a square hole in the heel of it, cut for that purpose; and this bar extending across the middle of the top-frame, the whole weight of the top-mast rests upon it; as does the top-gallant-mast in the same manner at the head of the top-mast.

As every mast is composed of three pieces, it will be also necessary to inform our readers that all ships, properly so called, are furnished with three masts, viz. the main-mast, the fore-mast, and mizen-mast. Those which have only two or one mast, are not called ships by seamen, but vary their names according to their method of rigging. Of two masts, there are snows, brigs, blanders, ketches, buffes, schooners, and hermaphrodites, among the English. Among the Spaniards and Italians, settees, barco-longas, feluccas, &c. Those of one mast are sloops, tartans, bean-cods, shallops, &c.

In the British navy, masts are proportioned to the extreme breadth of the ship from out to out.

Proportion for the length of masts, Anno 1745.

|                            |          | Guns.     |

| 1000: fore-top-<br>mast :: | { 480: } | fore-top- { 100, 90, 80,     |
|                            | { 505: } | gallant-mast { all the rest. |

The proportion for masting ships in the merchants service, is generally regulated by the judgment and experience of the commander.

The main and fore-mast in all ships down to 60 guns, one inch diameter to every yard in length.

For 50 and 40 guns, twenty-seven twenty-eighths of an inch diameter to one yard in length.

For 24 guns, twelve thirteenths of an inch in diameter to one yard in length.

All top-masts are nine-tenths of an inch in diameter to one yard in length.

The fore-top-mast as big as the main-top-mast.

The top-gallant-mast, one inch to a yard.

The mizen-mast, fifteen twenty-seconds of an inch to one yard in length.

The mizen-top-mast, five-sixths of an inch to one yard in length.

The bowsprit, an inch and a half to one yard.

The jib-boom, seven-eighths of an inch to a yard. See the articles BOWSPRIT and JIB-BOOM.

MASTER, *Magister*, in general, is a title of authority; as the grand master of Malta, the master of St. Lazarus, &c.

MASTER of a *Ship of War*, an officer who has the charge of navigating the ship from port to port, under the direction of the captain; the management and disposition of the sails, the conducting the ship in all extremities of danger, and directing her motions in the time of action, more particularly belongs to him; as also to superintend the provisions, and see that none are permitted to come aboard but such as are wholesome and sweet: he is also to take care that they are safely stowed by his mates and quarter-masters; these are also employed to superintend the navigation when he is off the deck, and to assist wherever his duty is concerned.

MASTER of a *Merchant-Ship*, the officer who commands and directs her course, manages her landing, and all other affairs.

MASTER at *Arms*, in the marine, an officer, whose

## M A S

whose business it is to confine and plant centries over the prisoners in a ship of war; to observe that all the lights and fire are put out when the evening gun fires, only such as are allowed by proper authority, or which are under the inspection of centries: he is also to attend the side when any boats come aboard, and search carefully that no spirituous liquors are brought into the ship, but what are permitted by the commanding-officer. He is likewise to teach the sea-men the exercise of the small arms, to which they generally have a great aversion; for this purpose, in large ships, the master at arms has several corporals under him to assist in his office, and relieve the centries and each other. See the article **CORPORAL**.

**MASTER Attendant**, in the king's dock-yards, an officer whose duty it is to observe that all the ships, which are laid up, or said to be in ordinary, are properly moored, cleaned, and kept in order; for which purpose he is often to visit and examine them; he also attends the musters in the dock-yard, to observe that all the men registered on the books do their duty: he has likewise the charge of the moorings, which are fixed in the river or harbour where he resides, and these he is always to keep in good repair, that they may be ready to moor the ships of war when necessary, which employment he must also see securely performed: he removes the ships from one place to another in the harbour, and pilots them into and out of the docks, &c. See the articles **DOCK-YARD**, **ORDINARY**, and **MOORINGS**.

**MASTER Shipwright**. See the article **SHIPWRIGHT**.

**MASTER of Arts** is the first degree taken up in foreign universities, and for the most part in those of Scotland; but the second in Oxford and Cambridge; candidates not being admitted to it till they have studied seven years in the university. See the article **DEGREE**.

**MASTERS in Chancery**, in ordinary, of which there are twelve, the master of the rolls being chief, are usually chosen out of the barristers of the common law, and sit in chancery, or at the rolls, as assistants to the lord chancellor and master of the rolls.

**MASTER GUNNER**. See **GUNNER**.

**MASTER of the Horse**, a great officer of the crown, who orders all matters relating to the king's stables, races, breed of horses; and commands the equerries and all the other officers and tradesmen employed in the king's stables. His coaches, horses, and attendants are the king's, and bear the king's arms and livery.

**MASTER of the Ordnance**, a great officer who has the chief command of the king's ordnance and artillery.

**MASTER of the Revels**, an officer who orders all

## M A S

things relating to the performance of plays, masks, balls, &c. at court.

**MASTER of the Rolls**, a patent officer for life, who has the custody of the rolls of parliament and patents which pass the great seal, and of the records of chancery, as also commissions, deeds recognizances, which being made of rolls of parchment, gave rise to the name.

**MASTERWORT**, in botany. See the article **IMPERATORIA**.

**MASTICH**, in the materia medica, a concrete resin, obtained in the island Chio from the Lentisk tree, brought over in small yellowish transparent grains or tears. From transverse incisions made in the bark of the tree, about the beginning of August, the resin exudes in drops, which running down and concreting on the ground, are thence swept up. The tree is raised also in several parts of Europe; but no resin has been observed to issue from it in these climates; nor do all the trees of this species in the island Chio itself, afford this commodity. See the article **LENTISCUS**.

This resin has a light agreeable smell, especially when rubbed or heated: in chewing, it first crumbles, soon after sticks together, and becomes soft and white like wax, without impressing any considerable taste.

Mastich is recommended, in doses from half a scruple to half a dram, as a mild corroborant and restraining, in old coughs, hemoptyses, diarrhoeas, weakness of the stomach, &c. It is given either in substance, divided by other materials; or dissolved in spirit, and mixed with syrups; or dissolved in water into an emulsion by the intervention of gum-arabic or almonds: the decoctions of it in water, which some have directed, have little or nothing of the virtue of the mastich.

**MASTICATION**, *Masticatio*, in medicine, the action of chewing, or of agitating the solid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into small pieces, impregnated with saliva, and so fitted for deglutation, and a more easy digestion.

**MASTICATORIES**, in medicine, such remedies as are taken in at the mouth; and chewed in order to promote the evacuation of the salival humour, as tobacco, ginger, pepper, sage, rosemary, thyme, mastich, &c.

**MASTIGADOUR**, **MASTICADOUR**, or **SLABBERING BIT**, in the manege, a snaffle of iron, all smooth, and of a piece, guarded with paternosters, and composed of the halves of great rings, made into demi-ovals, of unequal bigness; the lesser being inclosed within the greater, which ought to be about half a foot high. See the article **BIT**.

**MASTOIDES**, in anatomy, the same with *mammillaris*; being applied to such processes in the body

as

as have the appearance of breasts or dugs; arising in a broad basis, and terminating in an obtuse top. Mastoides is sometimes applied to the muscle which supports the head, proceeding from the neck-bone and breast-bone, and terminating in the process of the mammiformis.

**MAT**, among sailors, a sort of web or texture, formed of a variety of foxes, each of which consists of a certain number of rope yarns twisted together; the foxes are consequently larger or smaller, in proportion to the size of the mat required.

Mats are used to fasten on the outsides of the shrouds, and backstays, to prevent them from being chafed or fretted by the motion of other ropes which bear against them; also to lash on several block-strops, &c. for the same purpose; the largest sort of them are called panches. See the article **PANCH**.

**MATCH**, a kind of rope slightly twisted, and prepared to retain fire for the uses of the artillery, mines, fireworks, &c.

It is made of hempen tow, spun on the wheel like cord, but very slack; and is composed of three twists, which are afterwards again covered with tow, so that the twists do not appear: lastly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole be consumed: the hardest and driest match is generally the best.

**MATCHING**, in the wine-trade, the preparing vessels to preserve wines and other liquors, without their growing sour or vapid. The method of doing it, as directed by Dr. Shaw, is as follows: melt brimstone in an iron ladle, and when thoroughly melted, dip into it slips of coarse linen cloth; take these out, and let them cool: this the wine-coopers call a match; take one of these matches, set one end of it on fire, and put it into the bung-hole of a cask; stop it loosely, and thus suffer the match to burn nearly out: then drive in the bung tight, and set the cask aside for an hour or two. At the end of this time examine the cask, and you will find that the sulphur has communicated a violent pungent and suffocating scent to the cask, with a considerable degree of acidity, which is the gas and acid spirit of sulphur. The cask may after this be filled with a small wine, which has scarce done its fermentation, and bunging it down tight, it will be kept good and will soon clarify: this is a common and very useful method, for many poor wines could scarce be kept potable even a few months without it.

**MATE of a Ship of War**, an officer under the master, whose duty it is to observe the navigation of the ship, and to keep the log strictly marked; to trim the sails in the fore-part of the ship, and to superintend all affairs relating to the cables, moorings, and riding of the ship; to command the boats in which provisions and water are brought to the ship,

and assist in stowing them after they arrive aboard. See the articles **LOG**, **MASTER**, and **TRIM**.

**MATE of a Merchant Ship**, the officer who commands the ship in absence of the commander, and shares the duty with him.

The number of mates both in ships of war and merchantmen, is in proportion to the size of a ship: a first rate man of war has six mates, and an East-India-man the same number.

**MATERIA SUBTILIS**, denotes a fine subtle matter which the Cartesians suppose to pervade and penetrate freely the pores of all bodies, to fill up all their pores so as not to leave the least vacuity or interstice between them; they had recourse to this machine to support the doctrine of an absolute plenum, and to make it consistent with the phenomenon of motion, &c. See the article **CARTESIAN PHILOSOPHY**.

**MATERIA CHEMICA**, a term used by authors to express such bodies as are the peculiar objects of chemical experiments.

**MATERIA MEDICA** comprehends all the substances either used in medicine in their natural state, or which afford preparations that are so; these belong partly to the animal, partly to the vegetable, and partly to the fossil kingdom.

**MATHEMATICS**, that science which considers magnitudes either as they are computable or measurable; that part which relates to number only, is called arithmetic; and that which relates to measure in general, whether length, breadth, depth, motion, force, &c. is called geometry.

The word is Greek, *μαθηματικη*, signifying the same thing, which is derived from *μαθητης*, a disciple, and that from *μανθανω*, to teach.

The first who cultivated mathematics after the flood were the Assyrians and Chaldeans, from whom, says Josephus, they were carried by Abraham to the Egyptians, and among these Aristotle fixes the first rise of mathematics. From Egypt, 584 years before Christ, they passed into Greece through the hands of Thales; after him came Pythagoras, who paid a particular regard to arithmetic, fetching the greatest part of his philosophy from numbers; he first, according to Laetius, abstracted geometry from matter; and to him we owe the doctrine of incommensurable magnitude, the five regular bodies, besides the principles of music and astronomy. To him succeeded Anaxagoras, Oenopides, Briso, Antipho, and Hippocrates of Scio, who all applied to the quadrature of the circle, duplication of the cube, but the last with most success, and Proclus mentions him as the first compiler of mathematical elements.

Democritus excelled in mathematics as well as physics. The next is Plato, who not only improved geometry, but introduced it into physics. Out of his school proceeded a croud of mathematicians,

ticians, among whom was Leodamus, who improved the analysis first invented by Plato; Theætetus, who wrote on elements, and Archytas, who first applied mathematics to use in life. These were succeeded by Neocles and Theon. Eudoxus excelled in arithmetic and geometry, and was the first founder of a system of astronomy. Menechonus improved the elements.

Aristotle's works are stored with mathematics; out of whose school came Eudemus and Theophrastus; the first wrote of numbers, geometry, and invisible lines; the later a mathematical history. To Aristeus, Isidorus, and Hypsicles, we owe the book of solids, which, with the other books of elements, were improved and methodised by Euclid, who died 284 years before Christ.

An hundred years after Euclid, came Eratosthenes and Archimedes; cotemporary with the latter was Conon. Soon after came Apollonius Pergæus, whose conics are still extrant. Hipparchus and Menelaus wrote on the subtenses in a circle, the latter on spherical triangles. Theodorus's three books of spherics are still extant.

In the year 70, Ptolomy of Alexandria was born; he was succeeded by Plutarch the philosopher; after him was Eutocius, who commented on Archimedes, and occasionally mentions several inventions on the duplicature of the cube. To Ctesibius of Alexandria we owe our pumps; and Geminus came soon after, whom Proclus prefers to Euclid himself.

Diophantus of Alexandria was a great master of numbers, and first inventor of algebra. Nicomachus is celebrated for his arithmetical, geometrical, and musical works; Serenus, for his books on the section of the cylinder; Proclus, for his comments on Euclid; and Theon is, by some, thought to be the author of Euclid's Elements. Pappus of Alexandria flourished in the year 400, and his books of Mathematical Collections are still extant.

Dr. Barrow gives a most elegant description of the excellence and usefulness of mathematical knowledge, in his Inaugural Oration, upon being appointed professor of mathematics at Cambridge.

The mathematics, he observes, effectually exercise, not vainly delude, nor vexatiously torment studious minds with obscure subtilties; but plainly demonstrate every thing within their reach, draw certain conclusions, instruct by profitable rules, and unfold pleasant questions. These disciplines likewise enure and corroborate the mind to a constant diligence in study; they wholly deliver us from a credulous simplicity, most strongly fortify us against the variety of scepticism, effectually restrain us from a rash presumption, most easily incline us to a due assent, perfectly subject us to the government of right reason. While the mind is abstracted and elevated from sensible matter, distinctly views pure forms, conceives the beauty of ideas, and investi-

gates the harmony of proportions; the manners themselves are sensibly corrected and improved, the affections composed and rectified, the fancy calmed and settled, and the understanding raised and excited to more divine contemplations.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred astronomy, optics, geography, hydrography, hydrostatics, mechanics, fortification, navigation, &c. See the articles *ASTRONOMY*, *OPTICS*, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence, it is easy to put an end to all mathematical controversies, by shewing either that our adversary has not stuck to his definitions, or has not laid down true premises, or else, that he has drawn false conclusions from true principles, and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

*MATRICARIA*, feverfew, in botany. See *FEVERFEW*.

*MATRICULA*, a register kept of the admission of officers and persons entered into any body or society, of which a list is made.

*MATRIX*, *Uterus*, the womb, in anatomy, that part of the female of any kind, where the foetus is conceived and nourished till the time of its delivery. See *UTERUS*.

*MATRIX* also denotes a place proper for the generation of vegetables, minerals, metals.

*MATRIX*, in letter-foundry. See the article *FOUNDRY*.

*MATRONALIA*, a festival of the ancient Roman matrons, from whom it had its name. It was celebrated on the calends of March, in honour of the god Mars; and was to the Roman ladies what the festival of the Saturnalia was to their husbands; for at this time they served their women-slaves at table, and received presents from their husbands.

*MATROSSES* are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and spunging the great guns. They carry firelocks, and march along with the store waggons, both as a guard, and to give their assistance in case a waggon should break down.

*MATTER*, *Materia*, in physiology, whatever is extended and capable of making resistance: hence, because all bodies, whether solid or fluid, are extended and do resist, we conclude that they are material,

teral, or made up of matter. The Cartesians, it is true, make matter to consist in extension alone; but extension without resistance, is nothing but mere space. That matter is one and the same thing in all bodies, and that all the variety we observe arises from the various forms and shapes it puts on, seems very probable, and may be concluded from a general observation of the procedure of nature in the general formation and destruction of bodies. Thus, for instance, water, rarefied by heat, becomes vapour; great collections of vapours form clouds; these condensed descend in the form of hail or rain; part of this collected on the earth constitutes rivers, another part mixing with the earth enters into the roots of plants, and supplies matter to, and expands itself into various species of vegetables. In each vegetable it appears in one shape in the root, another in the stalk, another in the flowers, another in the seeds, &c. From hence various bodies proceed; from the oak, houses, ships, &c. from hemp and flax we have thread; from thence our various kinds of linen; from thence garments; these degenerate into rags, which receive from the mill the various forms of paper; hence our books; which by fire are converted partly into water, partly into oil, another part into air, a fourth part into salt, and a fifth into earth; which are called the elements of bodies; and which, mixed with common earth, are again resuscitated in various forms of bodies.

Sir Isaac Newton thinks it highly probable, that God in the beginning formed matter into solid, massy, impenetrable, moveable particles, or atoms, of such sizes and figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and that these primitive particles being solids, are incomparably harder than any porous bodies compounded of them, even so hard as never to wear or break in pieces; no ordinary power being able to divide what God himself made one in the first creation. While these particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of things depending on them may be changed. Water and earth, composed of old worn particles and fragments of particles, would not be of the same nature and texture now, with water and earth composed of intire particles in the beginning; and therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations of motions of these permanent particles, compound bodies being apt to break, not in the midst of solid particles, but where these particles are laid together, and only touch in a few points. See the article ATOM.

**MATTER in Deed**, in law, signifies a particular matter of fact to be proved by some deed, and is fre-

quently mentioned with matter of record; as where a man, during his absence abroad in the king's service, is sued to an exigent; in which case, if such person would take advantage of this matter in deed, he must alledge it before a scire facias for execution is awarded against him, otherwise he can have no relief but from matter of record; that is, some error in the proceedings appearing upon the face of the record.

**MATTHEW**, or *Gospel of St. MATTHEW*, a canonical book of the New-Testament.

St. Matthew wrote his Gospel in Judea, at the request of those he had converted, and it is thought he began it in the year 41, eight years after Christ's resurrection. It was written, according to the testimony of all the ancients, in the Hebrew or Syriac language, which was then common in Judea; but the Greek version of it, which now passes for the original, is as old as the apostolical times. St. Matthew's view in writing his Gospel, was chiefly to shew the royal descent of Jesus Christ, and to represent his life and conversation among men. No one of the Apostles enters so far into the particulars of the actions of Jesus Christ, or has given so many rules for the conduct of life. If we compare him with the other three evangelists, we may observe a remarkable difference in the order and succession of our Saviour's actions, from chap. iv. to chap. xiv. 13. Some have imputed this variation of St. Matthew to mere chance; and others, to choice and design: however, it can be no prejudice to the truth of the facts, which are the essential part of the Gospel; and as to the order of time, the sacred authors were not always solicitous about it.

**St. MATTHEW the Evangelist's Day**, a festival of the Christian church, observed on September the twenty-first.

**St. MATTHIAS's Day**, a festival of the Christian church, observed on the twenty-fourth of February.

**MATTINS**, the first canonical hour, or the first part of the daily service in the Romish church.

**MATURATION**, in surgery, the same with suppuration. See SUPPURATION.

**MAUNCH**, in heraldry, the figure of an ancient coat sleeve, borne in many gentlemen's escutcheons.

**MAUNDY-THURSDAY**, is the Thursday in Passion-week, which was called Maunday or Mandate Thursday, from the command which our Saviour gave his Apostles to commemorate him in the Lord's Supper, which he this day instituted; or from the new commandment which he gave them to love another, after he had washed their feet as a token of his love to them.

Our Saviour's humility in washing his disciples feet, is commemorated on this day by most Christian kings, who wash the feet of a certain number of poor people, not indeed with their own royal hands

hands, but by the hands of their lord almoner, or some other deputy.

**MAUROCENIA**, in botany, a genus of plants, whose flower consists of five oval petals, which spread open; it hath five subulated filaments, topped with obtuse antheræ: the fruit is an oval berry with one or two cells, each containing a single oval seed.

**MAUSOLEUM**, a magnificent tomb, or funeral monument. The word is derived from Mausolus, king of Caria, to whom Artimisia, his widow, erected a most stately monument, esteemed one of the wonders of the world, and called it, from his name Mausoleum.

**MAXILLA**, the jaws, or those parts of an animal in which the teeth are set.

The jaws are shorter in the human frame than in that of any other animal, in proportion to the size of the body; and this is a circumstance that adds greatly to the beauty of the face. The upper jaw is composed of thirteen bones, twelve of which are in pairs: these are, 1, the lachrymal; 2, the nasal; 3, the jugal; 4, the maxillar; 5, the spongiosum inferius; 6, the palatine; the thirteenth is an odd bone, and is called the vomer. These several bones of the upper maxilla are united to one another by a kind of juncture, which appears equal and even, and is called by anatomists *junctura per harmonium*.

The maxilla inferior, or lower jaw, is that moveable bone of the head which contains the lower series of teeth; this is composed of two bones which unite in the middle of the chin, by the intervention of a cartilage, which hardens as the child grows, and at length becoming bony, joins the two bones into a continued one, resembling the Greek  $\nu$ . It consists of two tables, between which there is a spongy substance, which in children is medullary. The fore-part is shallow, and just sufficient to contain the sockets of sixteen teeth. It has two processes, the coronoide and condyloides; four foramina or holes for the passage of blood-vessels and nerves, and six pair of muscles, of which two are depressors and four elevators; the depressors are called the platysmia myoides, and the biventer; and the four pair of elevators are, the crotaphites, the masseters, and the internal and external pterygoidæi, which see, under their several names. There is also the maxillary gland, situated on the inside under the lower jaw-bone. See the article **GLAND**.

**MAXIMUM**, in mathematics, denotes the greatest quantity attainable in any given case.

If a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then, on the contrary, grows lesser or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

The rule therefore to determine any flowing

quantity in any equation proposed, to an extreme value, is, having put the equation into fluxions, let the fluxion of that quantity (whose extreme value is sought) be supposed equal to nothing: by which means all those members of the equation in which it is found, will vanish, and the remaining ones will give the determination of the maximum or minimum required.

**Problem I.** To divide a given right line into two such parts, that their product, or rectangle, may be the greatest possible. This is the case, when the line is bisected, or divided into equal parts.

In any mechanical engine, the proportion of the power to the weight, when they ballance each other, is found by supposing the engine to move, and reducing their velocities to the respective directions in which they act; for the inverse ratio of these velocities is that of the power to the weight according to the general principle of mechanics. But it is of use to determine likewise the proportion they ought to bear to each other, that when the power prevails, and the engine is in motion, it may produce the greatest effect in a given time. When the power prevails, the weight moves at first with an accelerated motion; and when the velocity of the power is invariable, its action upon the weight decreases, while the velocity of the weight increases. Thus the action of a stream of water or air upon a wheel, is to be estimated from the excess of the velocity of the fluid above the velocity of the part of the engine which it strikes, or from their relative velocity only. The motion of the engine ceases to be accelerated when this relative velocity is so far diminished, that the action of the power becomes equal to the resistance of the engine arising from the gravity of the matter that is elevated by it, and from friction; for when these ballance each other, the engine proceeds with the uniform motion it has acquired.

**Prob. II.** Let  $a$  denote the velocity of the stream,  $u$  the velocity of the part of the engine which it strikes when the motion of the machine is uniform, and  $a-u$  will represent their relative velocity. Let  $A$  represent the weight which would ballance the force of the stream when its velocity is  $a$ , and  $p$  the weight which would ballance the force of the same stream if its velocity was only  $a-u$ ; then  $p:A::$

$\frac{a-u^2}{a^2} : a^2$ , or  $p = A \times \frac{a-u^2}{aa}$  and  $p$  shall represent the action of the stream upon the wheel. If we abstract from friction, and have regard to the quantity of the weight only, let it be equal to  $qA$  (or be to  $A$  as  $q$  to 1) and because the motion of the machine is supposed uniform,  $p = q \times A = \frac{A \times a - u^2}{au}$ , or  $q = \frac{a-u^2}{aa}$ . The momentum of this weight is  $qAu =$

$\frac{A u \times a - u^2}{a a}$ ; which is a maximum when the fluxion of  $\frac{a \times a - u^2}{a a}$  vanishes, that is, when  $u \times a - u^2 = 2 u u \times a - u = 0$ , or  $a - 3 u = 0$ . Therefore, in this case, the machine will have the greatest effect if  $u = \frac{a}{3}$ , or the weight  $q A = \frac{A \times a - u^2}{a a} = \frac{4 A}{9}$ . That is, if the weight that is raised by the engine be less than the weight which would ballance the power in the proportion of 4 to 9; and the momentum of the weight is  $\frac{4 A a}{27}$ .

Prob. III. Suppose that the given weight P (plate LXVI. fig. 6.) descending by its gravity in the vertical line, raises a given weight, W, by the cord P M W, (that passes over the pulley M) along the inclined plane B D, the height of which, B A, is given; and let the position of the plane B D be required, along which W will be raised in the least time from the horizontal line A D to B.

Let  $A B = a$ ,  $B D = x$ ,  $t =$  time in which W describes B D; then the force which accelerates the motion of W is  $P - \frac{a W}{x}$ ,  $t t$  is as  $\frac{x x}{P x - a W}$ , and if we suppose the fluxion of this quantity to vanish, we shall find  $x = \frac{2 a W}{P}$ , or  $P = \frac{2 a W}{x}$ ; consequently the plane B D required is that upon which a weight equal to  $2 W$  would be sustained by P; or if B C be the plane upon which W would sustain P, then  $B D = 2 B C$ . But if the position of the plane B D be given, and W being supposed variable, it be required to find the ratio of W to P, when the greatest momentum is produced in W along the given plane B D; in this case W ought to be to P as B D to B A +  $\sqrt{B D + B A} + \sqrt{B A}$ .

Questions of this kind may be likewise demonstrated from the common elementary geometry, of which the following may serve as an example:

Problem IV. Let a fluid, moving with the velocity and direction A C (fig. 7.) strike the plane C E, and suppose that this plane moves parallel to itself in the direction C B, perpendicular to C A, or that it cannot move in any other direction; then let it be required to find the most advantageous position of the plane C E, that it may receive the greatest impulse from the action of the fluid. Let A P be perpendicular to C E in P, draw A K parallel to C B, and let P K be perpendicular upon it in K; and A K will measure the force with which any particle of the fluid impels the plane E C, in the direction C B. For the force of any such particle being represented by A C, let this force be resolved into A Q, parallel to E C, and A P perpendicular to it; and it is manifest, that the latter A P only has any effect upon the plane C E. Let this force A P be resolved into

the force A L, perpendicular to C B, and the force A K parallel to it; then it is manifest, that the former, A L, has no effect in promoting the motion of the plane C E, in the direction C B. Let E M and E N be perpendicular to C A and C B, in M and N; and the number of particles, moving with directions parallel to A C, incident upon the plane C E, will be as E M. Therefore the effort of the fluid upon C E, being as the force of each particle, and the number of particles together, it will be as  $A K \times E M$ ; or, because A K is to A P ( $= E M$ ) as E N to C E, as  $\frac{E M^2 E M \times E N}{C E}$ ; so that

C E being given, the problem is reduced to this, to find when  $E M^2 \times E N$  is the greatest possible, or a maximum. But because the sum of  $E M^2$  and of  $E N^2 (= C M^2)$  is given, being always equal to  $C E^2$ , it follows that  $E N^2 \times E M^2$  is greatest when  $E N^2 = \frac{1}{3} C E^2$ ; for when the sum of two quantities A C and C B (fig. 8.) was given, A C  $\times$  C B<sup>2</sup> is greatest when  $A C = \frac{1}{3} A B$ , as will be very evident if a semicircle is described upon A D. But when  $E N^2 \times E M^2$  is greatest, its square root E N  $\times$  E M<sup>2</sup> is of necessity at the same time greatest. Therefore the action of the fluid upon the plane C E in the direction C B is greatest when  $E N^2 = \frac{1}{3} C E^2$ , and consequently  $E M^2 = \frac{2}{3} C E^2$ ; that is, when E M, the sine of the angle A C E, in which the stream strikes the plane, is to the radius, as  $\sqrt{2}$  to  $\sqrt{3}$ ; in which case it easily appears from the trigonometrical tables, that this angle is of  $54^\circ 44'$ .

Several useful problems in mechanics may be resolved by what we have just now shewn. If we represent the velocity of the wind by A C (fig. 7.) a section of the sail of a windmill perpendicular to its length, by C E, as it follows from the nature of the engine, that its axis ought to be turned directly to the wind, and the sail can only move in a direction perpendicular to the axis, it appears, that, when the motion begins, the wind will have the greatest effect to produce this motion, when the angle A C E in which the wind strikes the sail is of  $54^\circ 44'$ . In the same manner, if C B represent the direction of the motion of a ship, or the position of her keel, abstracting from her lee-way, and A C be the direction of the wind, perpendicular to her way, then the most advantageous position of the sail C E, to promote her motion in the direction C B, is when the angle A C E, in which the wind strikes the sail, is of  $54^\circ 44'$ . The best position of the rudder, where it may have the greatest effect in turning round the ship, is determined in like manner.

MAY, *Maius*, the fifth month of the year, consisting of thirty-one days. See the articles MONTH and YEAR.

MAYOR, the chief magistrate of a city or town, chosen annually out of the aldermen.

MEAD,

**MEAD**, a liquor made of honey, and held in great estimation by most of the northern nations, but perhaps not esteemed here so much as it might deserve, if due care was taken to prepare it properly.

All the writers who have hitherto treated of this subject, have given into a capital error with regard to the strength of this liquor, by directing too great a proportion of honey to be dissolved in the water. The usual practice of making it so strong as to bear an egg, is very wrong. The liquor is thereby rendered a mere stum, and this bad quality is still increased by the long boiling generally practised. It scarcely possible to procure honey so pure, but that some bee-bread, wax, or other substance is mixed with it, and this cannot be perfectly separated from it, but by boiling. On this account the boiling of mead seems indisputably necessary. In order the more effectually to separate these impurities from the liquor, it will be adviseable to mix some whites of eggs with it before it is put on the fire, and it will be particularly necessary to skim off the thick scum that rises, the moment the liquor begins to boil; and this must be attentively continued so long as it boils. The only method of boiling being here to separate the impurities, and to make a perfect union of the water and the honey, both which purposes are very soon obtained, it evidently appears that the boiling need be of but very short duration. This becomes here more peculiarly necessary, because the liquor will be the less disposed to ferment kindly, the longer the boiling has been continued. It is perhaps owing to the single article of long boiling, that mead has hitherto lain under so great discredit; because it then never fermented sufficiently to take off its luscious sweetness; whereas had it undergone a due fermentation, that sweetness would have gone off, and the mead would have attained a fine racy flavour.

Some notable housewives have added hops to their mead. This helps to take off its sweetness, and, as the bitterness of the hop goes off, gives it a pleasant flavour. A ferment is here, as in all liquors that are boiled, generally wanted to bring on a perfect fermentation: but as the least taint in the ferment is communicated to the whole liquor, particular care should be taken that it be very sweet and good. Mead, judiciously managed on these principles, will keep for years, and be improved by age.

**MEADIA**, in botany, the same with the dodecatheon of Linnaeus. See **DODECATHEON**.

**MEADOW**, in its general signification, means pasture, or grass land, annually mowed for hay; but is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them in the winter, without spoiling the sward.

Too much or too little water is almost equally prejudicial to meadows, but the best land for mea-

dows is a rich soil, that has a moist bottom, especially where a small brook may be brought over it, and where there is such a descent that the water will not lodge: these are better than those by great rivers, where the crops are often lost.

Those that may be overflowed at pleasure, are called water-meadows; these should never be overflowed till the end of March, except once or twice in winter, when there are such floods as bring down a great deal of soil from the upper-lands, and if the season should prove dry, it will be of great service to the grass, if the meadows are overflowed again; but then the cattle should not be turned in till the sward is dry enough to bear their weight. Miller recommends the weeding of meadows in April and October, with a spaddle, and rolling them with a heavy roller in spring and autumn. See **PASTURE**.

**MEAN**, in general, denotes the middle between two extremes: thus we say, mean distance, mean proportion, &c.

**MEASLES**, in medicine, a cutaneous disease, attended with a fever, in which there is an appearance of eruptions that do not tend to suppuration.

The measles are in general not dangerous, unless from an insalubrious epidemical constitution of the year, which sometimes renders them malignant: which may be known by a sudden loss of strength, coldness of the extreme parts, great restlessness, and a delirium. Those who die of the measles are generally suffocated on the ninth day. Some have a looseness, which continues several weeks, and brings on a mortal tabes. Some have a slow fever, with an atrophy and a swelling of the abdomen, which are fatal; and when a cough and hoarseness remain after the disease, a consumption will follow without speedy assistance.

If children are suspected to abound with crudities in the intestines, it will be proper to evacuate with half a grain of tartar emetic, and syrup of succory with rhubarb. When there are worms, anthelmintics should be given. In adults abounding with blood, phlebotomy is necessary on the first days; and as soon as the eruption is ended a gentle cathartic is proper: in a cough, nothing is better than oil of almonds fresh drawn, mixt with syrup of capillaire; half a spoonful of which should be often given in water-gruel. The patient should keep his bed for two days after the first eruption, and take absorbent and diaphoretic powders, to which half a grain of saffron may be added; these should be taken every night from the first onset of the disease, till the patient recovers, encreasing or diminishing the dose according to his age. If after the measles disappear, they should be followed by a difficulty of breathing, a fever, and other symptoms of an inflammation of the lungs, let blood be taken freely from the arm, once, twice, or three times, as occasion shall require, leaving a due space between each bleeding, and give

## M E A

divided into as many equal parts as the time is conceived to be divided into; the quantity of space answering to such an article of time is the measure of the velocity. See the article **VELOCITY**.

MEASURE, in a legal and commercial sense, denotes a certain quantity or proportion of any thing bought, sold, valued, or the like. Measures are then various, according to the various kinds and dimensions of the things measured. Hence arise linear or longitudinal measures, for lines or lengths; square measures, for areas or superficies; and solid or cubic measures, for bodies and their capacities. All which again are very different in different countries, and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c.

*Long MEASURES, or MEASURES of Application.*

The English standard long measure for commerce, or that whereby the quantities of things are ordinarily estimated in the way of trade, is the yard, containing three English feet. Its divisions are the foot, span, palm, inch, and barley-corn; its multiples the pace, fathom, pole, furlong, and mile. The proportions these severally bear to each other, are expressed in the following table:

| Barley-corns |      | English MEASURES of Length. |      |      |      |     |      |      |       |      |   |      |   |        |   |      |    |         |   |       |
|--------------|------|-----------------------------|------|------|------|-----|------|------|-------|------|---|------|---|--------|---|------|----|---------|---|-------|
| 3            | Inch | 3                           | Palm | 3    | Span | 1   | Foot | 1    | Cubit | Yard | 1 | Pace | 2 | Fathom | 2 | Pole | 40 | Furlong | 8 | Mile. |
| 9            |      | 9                           |      | 9    |      | 1   |      | 3    |       | 3    |   | 1    |   | 1      |   | 2    |    | 1       |   |       |
| 27           |      | 12                          |      | 4    |      | 2   |      | 5    |       | 2    |   | 2    |   | 3      |   | 110  |    | 320     |   |       |
| 36           |      | 18                          |      | 6    |      | 2   |      | 6    |       | 4    |   | 5    |   | 3      |   | 132  |    | 420     |   |       |
| 54           |      | 36                          |      | 12   |      | 4   |      | 16   |       | 11   |   | 16   |   | 5      |   | 176  |    | 560     |   |       |
| 108          |      | 60                          |      | 20   |      | 6   |      | 24   |       | 22   |   | 24   |   | 8      |   | 288  |    | 840     |   |       |
| 180          |      | 72                          |      | 24   |      | 8   |      | 32   |       | 30   |   | 32   |   | 10     |   | 360  |    | 1120    |   |       |
| 216          |      | 96                          |      | 32   |      | 10  |      | 40   |       | 36   |   | 40   |   | 12     |   | 480  |    | 1440    |   |       |
| 594          |      | 108                         |      | 66   |      | 22  |      | 66   |       | 60   |   | 66   |   | 22     |   | 880  |    | 2240    |   |       |

N. B. The aunes or ells of Amsterdam, Haerlem, Leyden, the Hague, Rotterdam, and other cities of Holland, as also that of Nuremberg, being all equal, are comprehended under that of Amsterdam; as those of Osnabrug are under those of France; and those of Bern and Basil are equal to those of Hamburg, Francfort, and Leipzig.

For the subdivisions and multiples of each of these measures of length, see the article AUNE, &c.

For the proportion of the feet of the principal nations in Europe, compared with the English foot, see the article FOOT.

*Square, or Superficial MEASURES.* English square or superficial measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard: the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the following table:

## English Square-MEASURES.

| Inches  | Feet  | Yards | Paces  | Poles | Rood | Acre. |
|---------|-------|-------|--------|-------|------|-------|
| 144     | 12    | 3     | 4      | 1     | 40   | 1     |
| 1296    | 36    | 9     | 12     | 3     | 1    | 1     |
| 3600    | 60    | 25    | 27     | 7½    | 4    | 1     |
| 39204   | 272¼  | 30¼   | 10.89  | 1     | 1    | 1     |
| 1568160 | 10890 | 1210  | 435.6  | 40    | 1    | 1     |
| 6272640 | 43560 | 4840  | 1743.6 | 160   | 4    | 1     |

Grecian square-measures were the plethron, or acre, by some said to contain 1444, by others 10000 square feet; and the aroura, the half of the plethron. The aroura of the Egyptians was the square of 100 cubits.

*Cubical MEASURES, or Measures of Capacity for Liquids.*—The English measures were originally raised from troy-weight; it being enacted by several statutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine-measure, the divisions and multiples whereof were to form the other measures; at the same time it was also ordered, that there should be but one liquid measure in the kingdom: yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard-gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter standard are raised two several measures, the one for ale, the other for beer.

The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches; and on this supposition the other measures raised therefrom, will contain as in the following table: yet by actual experiment, made in 1688, before the lord-mayor and the commissioners of excise, this gallon was found to contain only 224 cubic inches: it was however agreed to continue the common supposed contents of 231 cubic inches; so that all computations stand on their old footing. Hence as 12 is to 231, so is 14½ to 281½ the cubic inches in the ale-gallon: but in effect the ale-quart contains 70½ cubic inches, on which principle the ale and beer-gallon will

## M E A

will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the following tables:

English MEASURE of Capacity for Liquids.  
Wine-measure.

In the modern liquid-measures of foreign nations, it is to be observed, that their several vessels for wine, vinegar, &c. have also various denominations, according to their different sizes, and the places wherein they are used. The Woeders of Germany, for holding Rhenish and Moselle wines, are different in their gauges; some containing 14 aumes of Amsterdam measure, and others more or less. The aume is reckoned at Amsterdam for 8 steckans or 20 verges, or for  $\frac{2}{3}$  of a ton of 2 pipes; or 4 barrels of France or Bourdeaux, which  $\frac{1}{3}$  at this latter place is called tiercon, because 3 of them make a pipe or 2 barrels, and 6 the said ton. The steckan is 16 mingles, or 32 pints; and the verge is, in respect of the said Rhenish and Moselle and some other sorts of wine, of 6

M E A

mingles; but in measuring brandy, it consists of  $6\frac{1}{2}$  mingles. The aume is divided into 4 anckers, and the ancker in to 2 steckans, or 32 mingles. The ancker is taken sometimes for  $\frac{1}{24}$  of a ton, or 4 barrels, on which footing the Bourdeaux barrel ought to contain at Amsterdam (when the cask is made according to the just gauge)  $12\frac{1}{2}$  steckans, or 200 mingles, wine and lees; or 12 steckans, or 192 mingles racked wine; so that the Bourdeaux ton of wine contains 50 steckans, or 800 mingles, wine and lees; and 48 steckans, or 768 mingles of pure wine. The barrels or poinçons of Nantes and other places on the river Loire, contain only 12 steckans Amsterdam measure. The wine ton of Rochelle, Cognac, Charente, and the Isle of Rhé, differs very little from the ton of Bourdeaux, and consequently from the barrels and pipes. A ton of wine of Chalosse, Bayonne, and the neighbouring places, is reckoned 60 steckans, and the barrel 15, Amsterdam measure.

The muid of Paris contains 150 quarts, or 300 pints, wine and lee; or 280 pints clear wine; of which muids 3 make a ton, and the fractions are,

|                 |                |                |
|-----------------|----------------|----------------|
| The muid        | } containing { | 36 setiers     |
| The setier      |                | 4 quarts       |
| The quart       |                | 2 pints        |
| The pint        |                | 2 chopins      |
| The chopin      |                | 2 demi-setiers |
| The demi-setier |                | 2 poiffons.    |

The muid is also composed of pipes, or poinçons, quarteaux, queves, and demiqueves: these poinçons of Paris and Orleans contain about 15 fleckans Amsterdam-measure, and ought to weigh with the cask 666 lb. a little more or less. In Provence they reckon by milleroles, and the millerole of Toulon contains 66 Paris-pints, or 100 pints of Amsterdam, nearly; and the Paris-pint is nearly equal to the English wine-quart.

The butts or pipes from Cadiz, Malaga, Alicante, Benecarlo, Saloe, and Mataro, and from the Canaries, from Lisbon, Oporto, and Fayal, are very different in their gauges, tho' in affightments they are all reckoned two to the ton.

Vinegar is measured in the same manner as wine; but the measures for brandies are different: these spirits from France, Spain, Portugal, &c. are generally shipped in large casks called pipes, butts, and pieces, according to the places from whence they are exported, &c. In France, brandy is shipped in casks called pieces at Bourdeaux, and pipes at Rochelle, Cognac, the Isle of Rhé, and other neighbouring places, which contain some more and some less: even from 60 to 90 Amsterdam-verges or veertels, according to the capacity of the vessels, and the places they come from, which being reduced into barrels, will stand as follows, viz.

|                                   |    |          |               |
|-----------------------------------|----|----------|---------------|
| At Rochelle, Cognac, the Isle of  | 27 | veertels | } per barrel. |
| Rhé, and the country of Anunis    | 29 | veertels |               |
| At Nants, and several places of   | 32 | verges   |               |
| Bretagne and Anjou — —            | 30 | veertels |               |
| At Bourdeaux, and different parts | 30 | verges   |               |
| of Guienne — —                    | 27 | verges   |               |
| At Amsterdam, and other cities of |    |          |               |
| Holland — —                       |    |          |               |
| At Hamburg and Lubeck — —         |    |          |               |
| At Embden — —                     |    |          |               |

In Provence and Languedoc, brandy is sold by the quintal, the casks included; and at Bruges, in Flanders, the verges are called festers of 16 stops each, and the spirit is sold at so much per stop.

Olive-oil is also shipped in casks of various sizes, according to the custom of the places where it is embarked, and the conveniency of stowage. In England it is sold by the ton of 236 gallons; and at Amsterdam by the ton of 717 mingles, or 1434 pints. In Provence it is sold by millerols of 66 Paris-pints: from Spain and Portugal it is brought in pipes, or butts, of different gauges; at the first place it is sold by roves, whereof 40 go to the butt; and at the latter place by almoudas, whereof 26 make a pipe. Train-oil is sold in England by the ton, at Amsterdam by the

MEASURES of Capacity for Things dry. English dry or corn-measures are raised from the Winchester-gallon, which contains  $272\frac{1}{4}$  solid inches, and ought to hold of pure running water 9 pounds 13 ounces. This seems to stand on the foot of the old wine-gallon of 224 cubic inches, 12 being to  $14\frac{2}{3}$  as 224 to  $272\frac{1}{4}$ ; but by an act of parliament made in 1697 it is decreed, that a round bushel,  $18\frac{1}{2}$  inches wide, and 8 deep, is a legal Winchester-bushel. Now such a bushel will only hold 2150.42 cubic inches, consequently the gallon will hold 268.8 cubic inches, the divisions and multiples whereof are in the following table:

English Dry or Corn-MEASURE.

| Solid inches |      |        |               |
|--------------|------|--------|---------------|
| 33.6         | Pint |        |               |
| 268.8        | 8    | Gallon |               |
| 537.6        | 16   | 2      | Peck          |
| 2150.4       | 64   | 8      | 4 Bushels     |
| 17203.2      | 512  | 64     | 32 8 Quarter. |

In the several parts of Europe, salt, which is a more staple and current commodity than any other, is bought and sold by different measures, according to the several places of its dispatch: at Amsterdam it is sold by the cent of 404 measures, or scheppels, which cent is reckoned to be seven lasts, or 14 tons, and the last is to weigh 4000 lb. the seven lasts making 28000 lb. called the cent of salt, which also contains 208 facks; though some of this commodity is much heavier than others. In the cities of France, salt is sold by the muid, whose size varies according to the different places of its manufacture and dispatch. At Paris this measure is reckoned to contain 12 setiers, or 48 minots, which minot is also divided into other measures. The cent of salt from Marans, Brouage, Sude, and the Isle of Rhé, contain 28 stricken muids, and each muid 24 boiseaux, which yields at Amsterdam  $11\frac{1}{2}$  lasts, or 23 tons, more or less. In Copenhagen, the said cent renders only  $9\frac{1}{2}$  lasts, the last being reckoned here equal to 18 tons, and 50 lasts to correspond with 52 of Coningsberg, at which place the cent produces about 10 lasts, or 40,000 lb. At Riga the said cent yields the same measure as at Coningsberg, and about  $6\frac{1}{4}$  lasts of Riga, make the great cent of Amsterdam. The said French cent produces at Dantzick from  $11\frac{1}{2}$  to 12 lasts, of which lasts from  $7\frac{1}{4}$  to  $7\frac{1}{2}$ , make likewise the great cent of Amsterdam. At Stetin in Pomerania, the French cent yielded 10 lasts, making 40,000 measure and weight of the said place. In Portugal it is bought by the muid, of which four make a last, and seven the cent of Amsterdam. At Alamat and Ivica it is sold by the modin, which weighs from  $27\frac{1}{2}$  to 28 hundred weight English.

MEASURE of Wood, for firing. See the article CORD of Wood.

MEASURE for Horses, is the hand, which by statute contains four inches.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable. See METRE.

MEASURE, in music, the interval or space of time which the person who beats time takes between the rising and falling of his hand, in order to conduct the movement sometimes quicker and sometimes slower, according to the music or subject that is to be sung or played. See TIME.

MEATUS AUDITORIUS, in anatomy, the auditory passage. See the article EAR.

MECHANICS, that branch of mathematics which considers motion and moving powers, their nature and laws, with their effects in machines.

The knowledge of mechanics is one of those things, says Mr. Mac Laurin, that serves to distinguish civilized nations from barbarians. It is by this science, that the utmost improvement is made of every power and force in nature; and the motions of the elements, water, air, and fire, are made

made subservient to the various purposes of life: for however weak the force of man appears to be, when unassisted by this art; yet, with its aid, there is hardly any thing above his reach. It is distinguished, by Sir Isaac Newton, into practical and rational mechanics; the former of which treats of the mechanical powers, viz. the lever, ballance, axis and wheel, pulley, wedge, screw, and inclined plane. See the articles LEVER, BALLANCE, &c.

Rational mechanics comprehends the whole theory of motion; shews, when the powers or forces are given, how to determine the motions that are produced by them; and, conversely, when the phenomena of the motions are given, how to trace the powers or forces from which they arise. See MOTION.

MECHANICAL, an epithet applied to whatever relates to mechanics; thus we say, mechanical powers, causes, &c. See the articles POWER, CAUSE, &c.

The mechanical philosophy is the same with what is otherwise called corpuscular philosophy. See the article CORPUSCULAR.

MECHANICAL, in mathematics, denotes a construction of some problem, by the assistance of instruments, as the duplicature of the cube and quadrature of the circle, in contradistinction to that which is done in an accurate and geometrical manner.

MECHANICAL Curve, is a curve, according to Descartes, which cannot be defined by any algebraic equation: and so stands contradistinguished from algebraic or geometrical curve.

Leibnitz and others call these mechanical curves transcendental, and dissent from Descartes in excluding them out of geometry. Leibnitz found a new kind of transcendental equations, whereby these curves are defined: but they do not continue constantly the same in all points of the curve, as algebraic ones do.

MECHOACAN, in the materia medica, the root of an American convolvulus, brought chiefly from a province in Mexico of the same name, in thin transverse slices, like jalap, but larger and whiter.

This root was first introduced about the year 1524, and continued in esteem for a considerable time, as a mild cathartic, of very little taste or smell, not liable to offend the stomach, of slow operation, but effectual and safe: by degrees it gave place to jalap, which has now, among us, almost wholly superseded its use. It seems to differ from jalap only in being weaker: the resins obtained from the two roots have the same qualities, but mechoacan scarcely yields one sixth part so much as jalap does, and hence requires to be given in much larger doses to produce the same effects. The dose of the mechoacan in substance is from one dram to two or more.

MECONIUM, in medicine, a black thick fœces gathered in the intestines of infants, and brought with them into the world at the time of their birth. The retention of these fœces is one of the diseases to which infants are liable.

MECONIUM, in pharmacy, the extract of English poppies.

MEDAL, a piece of metal in the form of coin, intending to convey to posterity the portrait of some great person, or the memory of some illustrious action.

The parts of a medal are the two sides, one of which is called the face, or head, and the other the reverse. On each side is the area, or field, which makes the middle of the metal; the rim, or border; and the exergue; and on the two sides are distinguished the type, or the figure represented, and the legend, or inscription.

There was formerly no difference between money and medals. An old Roman had his purse full of the same pieces that we now preserve in cabinets. As soon as an emperor had done any thing remarkable, as gaining a victory, giving up a tax, or the like, it was immediately stamped on a coin, and became current through his whole dominions. This was a pretty device to spread abroad the virtues of an emperor, and make his actions circulate; and thus a fresh coin was a kind of gazette, that published the latest news of the emperor.

MEDALLION, or MEDALION, a medal of an extraordinary size, supposed to be anciently struck by the emperors for their friends, and for foreign princes and ambassadors; but that the smallness of their number might not endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins.

Medallions, in respect of the other coins, were the same as modern medals in respect of modern money: they were exempted from all commerce, and had no other value but what was set upon them by the fancy of the owner. Medallions are so scarce that there cannot be any set made of them, even though the metals and sizes should be joined promiscuously.

MEDEOLA, in botany, a genus of the hexandria-trigynia class of plants, the flower of which consists of six oblong, patent, and revolute petals: the fruit is a berry of a roundish form, with three cells, in each of which is contained a single cordated seed.

MEDIAI, or ALLIGATION MEDIAL, in arithmetic. See ALLIGATION.

MEDIANA, a vein formed by the concurrence of the cephalic and basilic veins in the bend of the elbow.

MEDIASTINUM, in anatomy, is a double membrane continuous to the sternum, situated unde-

der it, and adhering firmly to it. It divides the cavity of the thorax longitudinally into two parts: but as it is not exactly under the middle of the sternum, but somewhat to the left-side, the right part of the thorax is larger than the left.

**MEDIASTINUM CEREBRI**, the same with the transverse septum of the brain. See **BRAIN**.

**MEDIATE**, or **INTERMEDIATE**, something that stands between and connects two or more terms, considered as extremes; in which sense it is opposed to immediate.

**MEDICAGO**, in botany, a genus of the diadelphia-decandria class of plants, with a papilionaceous flower, and a long compressed and crooked pod for its fruit.

This genus comprehends the medicago, medica falcata, and cochleata of authors.

**MEDICINE**, *Medicina*, or *Physic*, the art of healing, which, according to Boerhaave, consists in the knowledge of those things, by whose application life is either preserved sound and healthy, or, when disordered, again restored to its pristine healthiness.

Medicine is undoubtedly of the same date with diseases, and diseases are almost as ancient as the world itself. Men were long each his own physician; and it is hard to fix the time when it first was made an art and profession. In certain countries those who had been cured of some disease, wrote down how and by what remedies it had been affected, and deposited those accounts in the temples for the instruction of others in the like case. In other places, as Egypt and Babylon, the sick were exposed in public, that such as passed by, who might have been cured of the same disease, might give them advice.

The Egyptians cultivated medicine both more anciently and more learnedly than any other people. The Greeks disputed that glory with them, or at least followed them very close in it.

Before the Trojan war, Chiron the Thessalian, surnamed the Centaur, who was Achilles's governor, made himself famous by the cure of wounds, and knowledge of simples. *Æsculapius*, Chiron's disciple, did not give place to his master. Celsus places Pythagoras, Empedocles, and Democritus, in the number of celebrated physicians.

Physicians were distinguished into different classes, namely, empirics, because they followed experience almost entirely; others, of whom Hippocrates was the chief, joined reason with experience, hence called dogmatic or rational. Hippocrates first applied himself to the study of natural things in general, and afterwards to that of the human body in particular. He made a great proficiency in all the parts of physic. He was born 460 years before Christ, and was cotemporary with Democritus. He compiled a body of Greek medicine, which

continued a long time sacred and unaltered, and was the standing practice of many ages. At length Aretæus the Cappadocian digested it into an orderly body; after which it was several times altered and improved, till at length it was taken in hand by Galen of Pergamos, who lived in the year 131. He ascribed all he knew to Hippocrates, and explained every thing by the rigid doctrines of the peripatetics; and did both a great deal of service, and a great deal of mischief to the art; he being the first who introduced the doctrine of the elements, the cardinal qualities, the degrees, the four humours, &c. into medicine; and on which he made the whole art depend.

Other famous physicians after Hippocrates, were Diocles Carystius, Praxagoras, Chrysippus, Erasistrates, Herophilus, Serapion, Apollonius, Glaucias, Heraclides, Tarentinus, Dionysius, Crito, Menodotus, Theodas, Asclepiades, Themison, Theſſalus, Soranus, Cælius Aurelianus, Celsus, Oribasius, Aetius, Alexander Trallianus, Paulus Ægineta, Actuarius, Myrepsus, &c.

Physic had for some time got almost entirely into the hands of the Arabians, till the end of the fifteenth century, when the original authors, most of which they had translated, came to be read in their own language; at length, the immortal Harvey, overturning the whole theory of the ancients, by the discovery of the circulation of the blood, laid a new and certain basis for medicine. Since his time, it is improved by sure discoveries in anatomy, chemistry, mechanics, &c.

It does not appear that physicians were very common among the Hebrews, especially for internal maladies; but for wounds, fractures, bruises, and all external injuries, they had physicians who understood the dressing of them, and the application of certain medicaments, as rosin, balm, fat, &c. The Jewish authors speak very unfavourably of physicians.

We are told by Pliny, that Archagathus of Peloponnesus was the first physician that came to Rome in the consulship of L. Æmilius and L. Julius, A. U. C. 535. That is, the Romans, till his arrival, used only the simple empiric kind of physic, such as was practised by the first men. It seems, however, that several physicians came from Greece to Rome, though Cato had opposed it with his whole power.

Till Pliny's time, of all professions, that of medicine, as gainful as it was, was the only one no Roman had followed, because they thought it below them.

Without entirely deciding, as to the merit of the ancient and modern physic, they have each their peculiar advantages, which render both highly estimable; and no doubt but the experience of many ages must have added considerable lights to the knowledge

knowledge of the ancients. The new discoveries which have enriched the physic of the moderns may give it the preference to that of the ancients.

The physic of the ancients is perhaps to be preferred to that of the moderns, in being less profuse of medicines in sickness, and less desirous to precipitate cures; in observing the motions of nature with more attention, and assisting them with greater confidence; and in being contented to divide the honour of the cure with nature, without arrogating the whole glory of it to itself.

Physic, however useful and salutary, has had the misfortune of being made the butt of great men, especially among the Romans. Cato declared himself most strenuously against physicians, as we see in a letter to his son preserved by Pliny; but it is to be observed, that he means only the physicians from Greece. Pliny the naturalist was of much the same way of thinking, but his complaints extend only to persons of no repute, authority, or learning.

Extremes are not to be admitted upon this head, in which blind confidence and ill-grounded contempt may be equally dangerous.

In short, whether we consider our bodies or our medicines, physic must be very precarious. Our bodies are more compounded and unequal than other bodies are; most other creatures live on a simple diet, and are regular in their appetites; whereas man feeds almost upon every thing, and, where appetite fails, invention is called in to swell the account by high sauces and rich spices. Hence proceed such variety of diseases as distract the physician's skill. A healthy constitution is easily restored when out of order, nature in a great measure does its own work; whereas, in a disordered body, a physician must give a new constitution before he can perfect the cure.

Though our *materia medica* be large enough, and to look into our dispensatories, one would think no disease incurable; yet the mischief is, all those fine medicines do not always answer in the application, nor have they been found so sovereign in our bodies, as they are in our books: all which things have so distracted our physicians that they vary even in the most common method. In one age alkalies are in fashion, and in the next acids begin to recover credit: bleeding is practised by one nation, and condemned by their neighbours, &c.

Medicine is divided into five principal branches: the first considers the human body, life, and health, and the effects flowing therefrom; this is called physiology, the doctrine of the œconomy or use of the parts; and its objects are called *res naturales*, or things according to nature.

The second branch considers the diseases of the human body, their differences, causes, and effects: as it considers diseases, it is called pathology; as it enquires into the causes, ætiology; when it exa-

mines their differences, it is called nosology; and when it explains their effects, symptomatology. The objects of this branch are called *res preternaturales*, or beyond nature.

The third branch considers the signs or symptoms, and how to apply them to use; so as to judge both in a sound and diseased body what is or will be the degree, order, and effect of the health or disease. This is called *semieiotica*. Its objects are things both natural, non-natural, and preternatural.

The fourth branch considers the remedies and their use, whereby life may be preserved; whence it is called *hygieine*. Its objects are what we strictly call non-natural.

The fifth furnishes the *materia medica*, its preparation and manner of exhibiting, so as to restore health; and is called *therapeutica*, comprizing the *diætetica*, *pharmaceutica*, *chirurgica*, and *iatrica*.

**MEDICINES**, *Medicamenta*, whatever substances serve to restore health.

**MEDIETAS LINGUÆ**, in law, signifies a jury, or inquest impanelled, of which the one half are natives of this land, and the other foreigners.

**MEDITULLIUM** is used by anatomists for that spongy substance between the two plates of the cranium, and in the interstices of all laminated bones. See the article **DIPLOE**.

**MEDIUM**, in logic, the mean or middle term of a syllogism, being an argument, reason, or consideration for which we affirm or deny any thing: or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

**MEDIUM**, in philosophy, that space or region through which a body in motion passes to any point; thus æther is supposed to be the medium through which the heavenly bodies move; air, the medium wherein bodies move near our earth; water, the medium wherein fishes live and move; and glass is also a medium of light, as it affords it a free passage. That density or consistency in the parts of the medium, whereby the motion of the bodies in it is retarded, is called the resistance of the medium, which together with the force of gravity, is the cause of the cessation of the motion of projectiles.

*Subtile*, or *Ætherial* **MEDIUM**. See **ÆTHER**.

**MEDLAR**, *Mespilus*, in botany, &c. See the article **MESPILUS**.

**MEDULLA**, **MARROW**, in anatomy. See **MARROW**.

**MEDULLA OBLONGATA**, is the lower and medullary part of the cerebrum and cerebellum, formed into a kind of tail, and extended to the great foramen or hole in the occipital bone of the cranium, where it gives origin to the spinal marrow, and to the nerves of the brain. See the articles **BRAIN** and **NERVE**.

**MEDULLA SPINALIS**, or spinal marrow, is a continuation of the medulla oblongata of the brain,

and

and forms, as it were, a tail to that part. It is included in a kind of bony canal, formed by the vertebræ, and in this is continued from the head to the extremity of the os sacrum. Its length is therefore the same with that of the spina dorsæ, which is different in persons of different stature. Its thickness, in general, is nearly equal to that of a finger; but it is not uniformly of the same diameter throughout. Its substance, in the upper-part, as far as to the last vertebra of the thorax, is the same with that of the medulla oblongata of the brain, but somewhat tougher and more firm: they are externally of a medullary substance, that the nerves may easily make their way out; internally cineritious, and of the same nature with the cineritious or cortical part of the brain; but the lower part of them, from the last vertebra of the thorax to the extremity of the os sacrum, is fibrous and very tenacious, and is called *cauda equina*. The division of the spinal marrow is formed by means of a fissure; it is by this separated into a right and left part, or into two columns; but this separation is not continued to the center. Its proper integuments are no less than six: these are, 1. the bony canal, formed by the cavities of the twenty-four vertebræ, and the os sacrum: 2. the tunica, which is very strong, and connects the vertebræ within: 3. the cellular, or adipose coat, which, in fat persons, always contains more or less fat, and seems destined by nature to soften the former: 4. the dura mater, which is stronger in the upper-part, and finer and weaker in the lower; this loosely incloses the medulla in the spine, and in its anterior part is firmly connected with the vertebræ: 5. the tunica arachnoides, which in its anterior part, adheres very firmly to the pia mater, but in its posterior part is loose and fluctuating: 6. the pia mater, which surrounds every part of the spinal marrow, and all the nerves that arise from it, and enters also its longitudinal division. The arteries and veins of the spinal marrow enter at the apertures of the vertebræ, which give passage out to the nerves; they make a multitude of anastomoses, and are derived from the vertebrals of the neck, the intercostals and the lumbar. The nerves of the spine are thirty-one, or as others count them, thirty-two pair. These are composed each of a multitude of fibres, arising from the anterior and posterior parts of the medulla: these fibres afterwards unite, and are connected by, and covered with membranes, and in that state they constitute what we call nerves.

The uses of the spinal marrow are, to give origin to the before-mentioned pairs of nerves, which are principally distributed to the limbs and external parts; and to secrete and prepare a nervous fluid.

MEDUSA'S HEAD, in astronomy. See the article ALGOL.

MEDUSA'S HEAD, in botany, the English name for a species of euphorbium. See EUPHORBIVM,

MEI, or MISERERE MEI, in medicine. See MISERERE.

MEL, HONEY. See the article HONEY.

MELAMPYRUM, cow-wheat, in botany, a genus of plants, whose flower is monopetalous and ringent. The fruit is an oblong, acuminate, compressed capsule, with two cells, containing two ovate twin seeds.

MELANCHOLY, in medicine, a species of madness, being a kind of a delirium without a fever, usually attended with fear, heaviness, and sorrow, without any apparent cause. It is infinitely varied according to the temperament and ideas of the person affected therewith. See MADNESS.

The word is Greek, *μελαγχολία*, and formed of *μελας*, black, and *χολη*, bile or gall.

The causes evidently productive of melancholy are observed to be,

1. All things which fix, exhaust, or disturb the nervous fluid of the brain; such as violent and sudden frights, intense thinking upon any subject, excessive love, watchings, solitude, fear, and hysteric disorders.

2. Such things as hinder and disturb the generation, reparation, circulation, and various secretions and excretions of the blood, especially in the spleen, stomach, omentum, pancreas, mesentery, intestines, liver, uterus, and hæmorrhoidal vessels: so that, of consequence, melancholy may be produced by the hypochondriacal disorder; by acute diseases ill cured, and especially a phrenitis and burning fever; by an excess of all the secretions and excretions; by such aliments and drinks as are cold, tenacious, terrestrial, tart, and astringent; by violent heat long protracted and parching the blood; as also by a stagnant, moist, and cloudy air.

3. A naturally black, hairy, dry, slender, and robust constitution of body, a middle age, a quick, penetrating, and discerning genius.

If this disorder continues long, it produces stupidity, epilepsies, apoplexies, madness, convulsions, blindness, surprising fancies, laughter, weeping, sighing, sighs, eructations, flatulencies, anxieties; an urine sometimes copious and limpid like water, and at others highly thick; a retention, accumulation of the excrementitious blood in the vessels of the abdominal viscera, and often a sudden excretion of it; obstinate costiveness, frequent spitting of a thin matter, and an incredible ability of enduring watchings, hunger, and cold.

This disorder has often been cured by a supervening unseemly itch, sometimes resembling an elephantiasis; by numerous and large varices; by a copious discharge from the turgid hæmorrhoidal veins; and an evacuation of the black bile by vomit and stool.

Patients labouring under this disorder are generally injured by all medicines which impair the strength, and evacuate too forcibly; as also by those which

which throw the humours into too violent commotions, whether cordials, or medicines of whatever denomination.

Hence the best method of curing this disorder is, after a due observation of the first causes and the variety of patients constitutions, to accommodate various medicines to these causes, and various constitutions.

The several intentions of cure to be pursued, therefore, are, 1. To rouse, augment, and regulate the fluids of the brain and nerves; which is done, first, by diverting the mind from its usual object to others of an opposite nature: secondly, by inducing cautiously another disposition, or affection of mind, opposite to melancholy: thirdly, by humouring the perverse and false turn of the imagination: or, fourthly, by frequently opposing it with great vigour.

2. To remove those obstructions which are either the cause, or the effect, of a perverted imagination, by softening, incising, and stimulating the obstructing matter, by means of mineral waters, whey, visceral, hepatic, and antihypochondriac decoctions, waters invigorated with lixivial or compound salts, laxative preparations of mercury, emetics, motion, exercise, riding, sailing, uterine medicines, and such as promote the lochia, remedies which procure hæmorrhoidal discharges, baths, liniments, and plasters.

3. To alleviate the symptoms by venesection, immersion in cold waters, and the use of carminatives and opiates.

4. After due evacuations, to exhibit such things as are from experience known to exhilarate the mind, and corroborate all the parts of the body.

From what has been said, it is obvious that the perfect cure of this disorder, as well as of a great many others falsely accounted incurable, consists in the correction of the bilis atra, or melancholic humour.

When melancholy increases so far as to bring on an agitation of the fluids of the brain, capable of driving the patient into a raging fury, the disorder is called madness.

This only differs in degree from a dejected melancholy, is its offspring, arises from the same causes, and is generally to be cured by the same medicines.

In madness the muscles are generally surprisngly strong, the patient is afflicted with watchings, incredibly capable of enduring hunger and cold, distracted by terrible imaginations, and subject to those disorders called lycanthropia and cynanthropia; which see.

It is observable, that, upon dissecting those who have died of madness, the brain has been found dry, hard, and friable, with its cortical substance of a yellow colour, and its vessels turgid, varicose, and distended with black and viscid blood.

It is also observable, that, during this disorder, all the excretions have, in like manner, almost ceased.

Unexpected precipitation into the sea, and a submerision in it, continued as long as possible, constitute the principal remedy for it.

Madnesses, obstinate against all remedies, have often been removed upon the approach of varices, hæmorrhoidal discharges, dysenteries, dropsies, copious spontaneous hæmorrhages, tertian and quartan fevers.

Such a sort of madness sometimes arises after the body is, by an autumnal, violent, and long-continued intermittent fever, weakened and exhausted, both by the force of the disease, and repeated venesections and purgings. The madness is also generally brought on again by these very means.

This species of the disorder is only to be cured by the use of restoratives, cardiacs, and corroboratives, long persisted in; but, if it is treated with evacuation, it brings on an atrophy, a weakness, and an unsurmountable foolishness.

But a madness arising in robust vigorous persons, in the flower of their age, or of hot and plethoric habits, is to be cured by repeated venesections, interposing a brisk purge between each; and when the disorder is alleviated, it is to be treated with opiates and cardiacs. *Boerhaave's Aphorisms.*

MELANE, among physicians. See the article ALPHOS.

MELANTERIA, in natural history, a very beautiful fossil, of a dense, compact, and regular texture, and of an extremely bright pale yellow, resembling nothing so much as the purest gold: it is remarkably heavy, and is usually found in little irregular masses, of the bigness of a pigeon's egg, which are broken with a slight blow; but it is usually met with in the form of a fine gold-coloured efflorescence or vitriolic and pyritical bodies; or in loose, shattery, and friable masses, of a more dusky yellow, in which latter state, it so much resembles a native sulphur, that it is frequently mistaken for one: however, it is not inflammable, but calcines in the fire to a greyish powder, which by burning longer, changes to a deep and fine purple.

MELANTHIUM, in botany, a genus of plants whose flower consists of six ovato-oblong, patent petals, with six erect slender filaments, topped with globose antheræ: the fruit is an ovate trigonal capsule, with three cells, which contain a number of compressed semi-ovate seeds.

MELAPODIUM, in botany, a genus of plants whose flower is compound and radiated; the particular hermaphrodite corollulæ are situated in the disk, and the female ones form the rays: the stamina are five very small filaments, topped with tubulose cylindraceous antheræ: the seeds are oval, compressed, three-cornered, and placed on a conic paleaceous receptacle.

ME-

**MELASSES**, or **MOLASSES**. See the article **MOLASSES**.

**MELASTOMA**, in botany, a genus of plants, the flower of which consists of five roundish petals, with ten short filaments inserted in a ventricose cup; these are terminated by long erect antheræ, a little curved: the fruit is a roundish quinquelocular berry, containing many small seeds.

**MELCHITES**, in church history, the name given to the Syriac, Egyptian, and other Christians of the Levant. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect professed Greeks; but they are governed by a particular patriarch, who resides at Damas, and assumes the title of Patriarch of Antioch.

**MELCHIZEDECIANS**, in church history, a sect which arose about the beginning of the third century, and affirmed, that Melchizedech was not a man, but a heavenly power, superior to Jesus Christ; for Melchizedech, they said, was the intercessor and mediator of the angels, but Jesus Christ was so only for men, and his priesthood only a copy of that of Melchizedech. This heresy was revived in Egypt by one Hierax, who pretended that Melchizedech was the Holy Ghost.

**MELEAGRIS**, the turkey, in ornithology. See **TURKEY**.

**MELES**, the badger, in zoology. See the article **BADGER**.

**MELIA**, the bead-tree, in botany, a genus of plants, whose flower consists of a small monophyllous cup, cut into five obtuse segments at the top, with five narrow lanceolated petals which spread open, and a cylindraceous nectarium: the stamina are ten small filaments, inserted in the top of the nectarium, terminated by oblong antheræ: the fruit is a soft globular drupe, containing a roundish nut, having five furrows and five cells, each containing an oblong seed.

**MELIANTHUS**, honey-flower, in botany, a genus of plants whose flower is composed of four lanceolated petals, which are reflexed at their points: the fruit is a quadrangular capsule, containing four globose seeds.

**MELICA**, in botany, a genus of plants, whose flower is composed of two valves, not aristated: it hath no pericarpium; but the seed, which is single and ovate, is included in the corolla.

**MELICERES**, in surgery, a kind of encysted tumours, so called when their contents are of the consistence of honey; but when this is of the consistence of paste, they are called a *theromata*.

**MELILOT**, in botany, a species of trifolium: it grows naturally in several parts of England: the flowers are produced in long slender spikes, which come out from the wings of the stalks; they are papilionaceous, and of a bright yellow colour.

In pharmacy, melilot is scarce ever given internally; but in external use, it is a great emollient, resolvent, and digestive: it is a good ingredient in cataplasms and fomentations, and also in clysters. The flowers are recommended by some, in infusion, as a remedy against the fluor albus.

**MELISSA**, baum, in botany. See the article **BAUM**.

**MELITTIS**, in botany, a genus of plants, whose flower is monopetalous and ringent; the upper lip is plane, erect, and roundish, and the lower one is trifid and obtuse: the seeds, which are four in number, are placed in the bottom of the cup.

**MELOCHIE**, in botany, a genus of plants, whose flower consists of five large, cordated, spreading petals: the fruit is a roundish capsule, having five cells, each containing a single seed.

**MELODY**, in music, the agreeable effect of different sounds, ranged and disposed in succession; so that melody is the effect of a single voice or instrument, by which it is distinguished from harmony. See **HARMONY**.

**MELON**, in botany, makes a distinct genus of plants, the flowers of which consist only of one leaf each, and are wide at the mouth, and divided into several segments, wholly resembling the flowers of cucumbers: of these also, some are male or sterile flowers, having no embryo fruit; others are fruitful or female flowers, having an embryo, which ripens into a large fruit of an oval figure, sometimes smooth, sometimes rough, divided into three cells, and containing oblong seeds; each of these cells seems also to be divided into two.

There are great varieties of melons, but the best sorts we know of are the Romana and Cantaleupe melons, so called from the places where they have been first propagated in Europe, though they originally came from some parts of Asia. They are raised on hot-beds, nearly in the same manner as those of cucumbers; but the earth in which they grow, should be much stronger, and not more than two plants to one light; these, as they advance in growth, should be trained thin and regularly, so as to prevent confusion among the branches, being previously pinched off at the second joint, which produces lateral shoots, whose extremities should also be pinched off when they have five or six joints; this will occasion fresh branches to issue forth, which produce the fruit; these branches should likewise be pinched off at the joint beyond the fruit, which will help to set them, they being very liable, in bad weather, to turn yellow and come to nought; therefore, they are not set with certainty till they are arrived to the size of a hen's egg. Some, to set the fruit, use the method of taking the male flower, and striking its farina into the eye of the female flower, in order to impregnate the fruit, which is very proper, particularly to those early-raised plants, that can

can admit of but a small share of air being given them on account of its coldness. (See the article *Generation of PLANTS*). The fruit, when fully grown, should be often noticed for their being cut at a proper time, which is known by the stalk cracking round the part which join to the fruit, as likewise by the smell; but for those kinds of Cantaloupe melons whose rinds are thick, it is necessary to let them be on the branch a day longer than the other sorts after they have shewn the marks of ripeness; and if they are cut early in the morning, before the sun has warmed them, they will be much higher flavoured.

It may be necessary to observe, that the larger the glasses are, the better it will be for the plants, and the greater number of fruit will be obtained, which will also be larger and richer flavoured than those raised in the contracted glasses commonly used, which are not above four feet and a half in depth, which greatly prevents the plants from extending themselves, and makes it necessary either to pinch them too close, to keep them within the frame, or else the box must be raised to let them out underneath when the season will not admit of it, but this is to be understood of those which are raised in February or March; about six feet is a very good width for a melon-frame.

The first season for sowing melon-seeds is in January, and the last the latter end of April or beginning of May.

The seeds of melons are reckoned among the greater cold seeds; they are esteemed cooling and diuretic; they serve to make emulsions, but at present they are not so much noticed as formerly.

**MELONGENA**, mad-apple, in botany, a genus of plants, whose flower is monopetalous, with a short tube, and the limb cut into five segments, which are plicated and reflexed; the stamina are five small subulated filaments, terminated by oblong connivent antheræ. The fruit is a smooth, egg-shaped berry, with a fleshy pulp, having one cell, which contains a number of roundish compressed seeds.

A species whose fruit is white and much resembling an egg, is raised with us in the spring, on a common hot-bed, from seed, and afterwards transplanted in borders or pots as other annual plants are; these are preserved merely for the shew of the fruit; but in the warm parts of the globe they are eaten as a delicacy, which not in the least suits an English palate.

**MELON-THISTLE**, *Cactus*, in botany, a genus of plants shaped like a melon, with deep ribs beset with strong spines, and of a green colour; some of which are crowned with a prickly brown cap, which gives them a singular appearance. The flower is hexapetalous, and spreads open at the top, and the fruit is a fleshy berry with one cell, con-

taining a number of angular seeds. These plants are natives of the warmest parts of America, growing in the apertures of the rocks, having little or no earth to support them; therefore we are directed that those which are kept here should not have a rich soil for their support; the most proper for these plants is the rubbish of old buildings: they require to be kept in a hot-house constantly, and in winter should have scarce any water given them. To this genus Linnæus has joined the *cereus* and *opuntia* of other authors.

**MEMBRANE**, in anatomy, a pliable texture of fibres, interwoven together in the same plane.

The membranes differ in thickness, according to the smallness of their fibres, or the number of their planes. These particular planes are termed *laminæ*, and are distinguished into internal, external, and middle. The difference of membranes, in general, depends on that of the fibres of which they are composed. Small portions of membranes, especially when they are very thin, are called *pellicles*, and called the cellular or spongy substance.

**MEMBRANOSUS**, in anatomy, a muscle otherwise called *fascia lata*.

**MEMOIRS**, in matters of literature, a species of history, written by persons who had some share in the transactions they relate, answering to what the Romans call *commentarii*, commentaries.

**MEMORY**, *Memoria*, a faculty of the human mind, whereby it retains or keeps the ideas it has once perceived. See **IDEA**.

Memory (says Mr. Locke) is, as it were, the store-house of our ideas; for the narrow mind of man not being capable of having many ideas under view at once, it was necessary to have a repository, in which to lay up those ideas which it may afterwards have use of. But our ideas being nothing but actual perceptions in the mind, which cease to be any thing where there is no perception of them; this laying up of our ideas in the repository of the memory, signifies no more than this, that the mind has a power, in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings which we can bring in sight, and make the subjects of our thoughts, without the help of those sensible qualities which first imprinted them there.

Attention and repetition help much to the fixing ideas in our memories: but those which make the deepest and most lasting impressions, are those which are accompanied with pleasure and pain. Ideas but once taken in, and never again repeated, are soon lost; as those of colours, in such as lost their sight when very young.

The memory of some men is tenacious even to a miracle: but yet there seems to be a constant decay

cay of all our ideas, even of those which are struck deepest, and in minds the most retentive : so that, if they be not sometimes renewed, the print wears out, and at last there remains nothing to be seen.

Those ideas that are often refreshed, by a frequent return of the objects or actions that produce them, fix themselves best in the memory, and remain longest there : such are the original qualities of bodies, viz. solidity, extension, figure, motion, &c. and those that almost constantly affect us, as heat and cold.

In memory, the mind is often more than barely passive ; for it often sets itself on work to search some hidden ideas ; sometimes they start of their own accord ; and sometimes tempestuous passions tumble them out of their cells. This faculty, other animals seem to have to a great degree, as well as men, as appears by birds learning tunes, and their endeavour to hit the notes right. For it seems impossible that they should endeavour to conform their voices, as it is plain they do, to notes whereof they have no idea.

*Local MEMORY*, among orators, is nothing but the associating the different heads to be handled, with the objects before the speaker's eyes ; so that, by only looking around him, he is put in mind of what he is to say.

*Artificial MEMORY*, *Memoria Technica*, a method of assisting the memory, by forming certain words, the letters of which shall signify the date or æra to be remembered.

**MENDICANTS**, or begging friars, several orders of religious in Popish countries, who having no settled revenues, are supported by the charitable contributions they receive from others.

**MENIALS**, in law books, domestic or household servants, who live under their lord or master's roof.

**MENINGES**, or **MENYNGES**, in anatomy, a name given to the dura and pia mater of the brain.

**MENIPPEAN**, in poetry, a kind of satire, consisting of prose and verse intermixed.

**MENISCUS**, in optics, a lens, convex on one side and concave on the other. See **LENS**.

For finding the focus of a meniscus, the rule is, as the difference of the semi-diameters of the concavity and convexity, to the semi-diameter of the concavity ; so is the diameter of the convexity to the focal distance.

**MENNONITES**, a sect of baptists in Holland, so called from Mennon Simonis of Friezeland, who lived in the sixteenth century.

This sect believe, that the New-Testament is the only rule of faith ; that the terms Person and Trinity are not to be used in speaking of the Father, Son, and Holy Ghost ; that the first man was not created perfect ; that it is unlawful to swear or to wage war upon any occasion ; that infants are not the proper subjects of baptism ; and, that ministers of the Gospel ought to receive no salary.

**MENOLOGY**, the Greek calendar, in which the lives of the saints in short, or barely their names, are cited ; answering nearly to the martyrology of the Latin church.

**MENSALS**, *Mensalia*, in church history, such livings as were formerly united to the tables of religious houses, and hence called mensal benefices.

**MENSES**, *Catamenia*, fluors, courses, in medicine, are the monthly evacuations from the uterus of women not with child, and not giving suck.

The word is derived from the Latin *mensis*, a month, the period wherein they generally return.

The common cause of the stoppage of the menstrual discharges is the blood's lentor ; whereby this fluid becomes incapable of forcing the sphincters of the ducts destined by nature for this evacuation. For it is not from the bursted arteries of the uterus, which is the common opinion, that the blood issues every month, but from vessels peculiarly appropriated to this office. And this lentor, or thickness of the blood, changes the lively colour of the face into a greenish, pale, and wan complexion.

The proper medicines, in this distemper, are those which are capable of increasing the blood's circulation, and attenuating the viscid humours : and such are all bitters, joined with aromatics ; as also many preparations of steel. But to these ought to be premised blood-letting, and cathartics blended with calomel. The tinctura sacra is also an excellent medicine.

But of all the most powerful emmenagoges, I have found so singular virtue in black hellebore, that I hardly remember it ever failed answering my expectation. My way of ordering it is, a tea-spoonful of tincture of black hellebore in a glass of warm water, to be taken twice a day. And I have observed this remarkable circumstance, that whenever, either from a bad conformation of the parts, or any other cause, this medicine had not the desired effect, the blood was forced through some other passages ; which is a manifest proof of the great power of this medicine in spurring the blood forward.

But likewise the menstrual discharges frequently run to excess. In that case, the flux is to be restrained ; which, after letting blood, is effected, both by those medicines which condense and inspissate the blood and by those which allay its heat. Of the first sort, the principal are such as participate of vitriol or alum ; especially the tincture of roses ; or a powder composed of alum three parts, and dragon's-blood one part, melted together. But the heat of the blood, and its consequence, the flux, is more powerfully checked by the Peruvian bark, than by any other medicine whatsoever. *Mead.*

**MENSTRUUM**, or **DISSOLVENT**, in chemistry, a body which, when artificially applied to another, divides its subtilty, so that the particles of the solvent remain thoroughly intermixed with those of the solved.

It was called a menstruum, because the chemists, in its application to the solvend, first used a moderate fire, for a philosophical month, or forty days; and hence arose the name of menstrual solvent, at length barely a menstruum.

It is the property of a menstruum to be itself equally dissolved, when it dissolves the solvend; but when the solution is perfected, it may sometimes happen that the solvent and solvend shall separate. The divided parts, therefore, of a solvent, must insinuate itself among the parts of the solvend, so as to divide and dissolve the body. Hence it appears, that the actions of menstrooms differ from all mechanical separations, where the instrument, such as a knife, sword, or saw, while it divides, is not itself divided, but remains almost entire. But there is some reason to suspect, that the single particles of a menstruum act like mechanical instruments, by the properties of their own proper size, figure, hardness, and gravity. Every menstruum, while it dissolves, is necessarily divided into invisible particles, and must therefore be fluid in the action; and when the dissolution is completed, the solvent and solvend must become one fluid.

Custom has given the name of menstrooms to many bodies of a hard and consistent nature, though in that state they cannot act as solvents; and hence the chemists have divided menstrooms into solid and fluid.

Dry or solid menstrooms may be again divided into five classes, which, according to Boerhaave, are as follow: 1. The fix metals, gold, lead, silver, copper, iron, and tin, which act upon one another after being fused in the fire, and may be intimately mixed, so as to make an apparently homogeneous mass, every particle of which holds the same proportion of a different metal as the whole: for if ten ounces of silver be thus mixed with an ounce of gold, and a grain of this mass be given to an assay-master, he will discover that it contains one eleventh part gold, and ten parts silver. 2. The semi-metals, as antimony, bismuth, cinnabar, marcasites, and zinc, which, when melted, mix with one another or with metals; but when thus mixed they are no longer malleable, but may easily be reduced to powder. 3. The dry salts, as alum, borax, nitre, sal-ammoniac, sea-salt, vitriol, fixed alkali, and mercury sublimate, which may be subtilly divided by fire, and intimately mix with one another, with metals, semi-metals, and other things. 4. Hard fossil sulphureous bodies, as sulphur vivum, common brimstone, arsenic, orpiment and cobalt. 5. The fossil bodies, called by refiners cements, which consist of salts, sulphur, and brick, reduced to dry powders, and strewed betwixt plates of metals, in order to raise their colour, or separate one metal from another.

Some menstrooms being left to themselves, after solution concrete into a hard mass, which, though

compounded, appears of an uniform simple nature. In this manner, if melted lead be mixed with tin, they unite, as water with water, or mercury with mercury. The case is the same in all the metals, and in some of the semi-metals. Thus if a scruple of regulus of antimony be added to a pound of melted tin, the mass when cold will appear uniform, but become entirely brittle; so fixed alkali unites with sand in the fire; and sulphur and mercury, by being ground together, turn to a black and dry powder, which being sublimed, produces an apparent simple body, called cinnabar. Many become an hard, and sometimes a dry body. Thus almost all the menstrooms of metals unite with their respective metals into solid vitriols; and thus strong distilled vinegar, when it has dissolved shells, chalk, and stony substances, separates from its water, and together with the body it dissolves, forms a dry hard mass.

Numerous menstrooms have a liquid form before they act as solvents; as vinegar, water, saline, acid, alkaline, and compounded spirits, alkaline oils per deliquium, &c. Some menstrooms become liquid after the solution, and continue so with the solvent. Thus in the dissolution of five of the metals with simple mercury, a soft paste is produced, which may indefinitely be diluted by the addition of more mercury; but there is scarcely any known method of restoring this amalgama to its solidity. All the liquid menstrooms, after having dissolved metals in a large proportion, cannot easily be dried; whence many have imagined these solutions to be fixed metallic oils, and have in vain sought secrets in them.

It is now easy to observe that many menstrooms unite bodies as well as separate them; for frequently after the dissolution, the particles of the menstruum presently join with those of the solvent, and produce a new compound, often very different from the nature of the simple resolved body. The parts however of the solvent, after its concretion, no longer touch one another, but are separated by the interposition of the particles of the matter dissolved; and the particles which before constituted the solvend, are separated by the interposition of the particles of the solvent. Hence it is plain that the parts of the menstrooms apply themselves to the parts of the solvend; and a certain cause is here required to make the particles of the solvent fly from one another and approach the particles of the solvend, rather than remain in their former situation. The like cause seems to be required to make the particles of the solvend, now separated, remain united with the parts of the menstruum, rather than suffer the dissolving and dissolved particles to unite by their natural affinity into homogeneous bodies. This cause must be sought in the solvend as well as in the solvent, for the action is reciprocal. Thus while aqua regia dissolves thrice its weight of gold into a yellow

yellow liquor, the particles of gold are united with the aqua regia, and remain suspended in it, though gold be eighteen times heavier than aqua regia. Whence there must be a mutual corresponding power between the particles of the gold and aqua regia, whereby they act upon, embrace and detain each other, otherwise the particles of gold would fall to the bottom, the saline particles rest upon them, and the water float over both. If we were to deduce the cause from similitude of substance, the action of dissolution seems to be performed by a certain power of the parts of the menstruum to attract the dissolved parts rather than to repel them; and is not a mechanical action, or unfriendly commotion, but rather an appetite of union. Thus, in a violent solution, the agitation, heat, hissing and tumult cease when all the parts of the solvend have united with those of the solvent, as appears in throwing a piece of iron into weak aqua-fortis.

The whole solvent never acts at once upon the whole solvend, only those particles of the solvent which touch some others of the solvend act first; and these being separated, fresh particles of the menstruum apply themselves to others of the solvend: therefore part of the menstruum acts upon that part of the body which it strikes off and separates; but the conflict made in this separation excites a greater motion in the menstruum, by which means other parts of the menstrooms are agitated and applied to other parts of the solvend.

Fire excites, promotes, and increases the action of menstrooms; for in extreme cold, solutions are either not made, or made but slowly, but they are soon performed by the assistance of heat: some menstrooms require a strong heat, as mercury, before it will dissolve metals: some a smaller; thus sal ammoniac, sea salt, and salt of tartar, easily dissolve in water; some menstrooms act with a moderate heat, but lose their dissolving power, or even acquire a power of coagulating, by a stronger; thus warm water dissolves the whites of eggs, which boiling coagulates. This effect of fire seems to be produced, 1. By impelling, moving, and agitating the menstruum in the manner of a mere mechanical motion. 2. By its general power of expanding the substance of all bodies. 3. By separating the parts so as set them farther asunder. In most cases the heat is increased during the solution, and even the action of those menstrooms is augmented by heat, which degenerate a great degree of cold in the solution; thus sal ammoniac dissolves soonest in warm water.

Sir Isaac Newton accounts for the action of menstrooms, from the acids wherewith they are impregnated, which are found to be endued with a strong attractive force, wherein their activity consists. See ACID.

**MENSTRUUM**, in pharmacy, chiefly denotes a

body that will extract the virtues of ingredients by fusion, decoction, &c.

**MENSTRUUM Peracutum**, a menstruum which Mr. Boyle extracted from bread only, that would prey even on glass, and perform many things which aqua-fortis would not.

With this he drew tinctures from coral, lapis hæmatites, granates, diamonds, and rubies.

*Universal MENSTRUUM*. See ALKAHEST.

**MENSURATION**, *Menfuratio*, in general, denotes the act or art of measuring lines, superficies, or solids.

**MENTHA**, mint, in botany. See the article MINT.

**MENTZELIA**, in botany, a genus of plants, whose flower consists of five patent petals, with many setaceous erect stamina: the fruit is a long cylindraceous capsule, with one cell, containing many small seeds.

**MERCATOR's CHART**, a projection of the earth's superficies in plano, where the meridians are straight lines, parallel to, and equidistant from, each other. The parallels of latitude are also straight lines, and parallel to one another, but the distance between them increases from the equinoctial towards either pole, in the ratio of the secant of the latitude to the radius. See *Mercator's SAILING*.

**MERCHANT**, a person who buys and sells commodities in gross, or deals in exchanges; or that traffics in the way of commerce, either by importation or exportation. Formerly, every one that was a buyer or seller in the retail way, was called a merchant, as they still are both in France and Holland; but here, shop-keepers, or those who attend fairs or markets, have lost that appellation.

**MERCURIAL**, something consisting of, or relating to, mercury.

**MERCURIFICATION**, in chemistry, the method of separating the mercuries of metals, which is most easily effected by means of a burning-glass; for the metal being placed in its focus, its mercurial parts are said to fly off in smoke, which when condensed and collected, appears to be true quicksilver.

**MERCURY**, in natural history, a fluid metallic substance, not moistening the hands; perfectly opaque; of a bright silver colour, resembling lead or tin when melted; entirely void of taste and smell; extremely divisible; not congealable in the greatest degree of natural cold.

It is the most ponderous of all fluids, and of all known bodies except gold and platina; its gravity is to that of water nearly as 14 to 1; a cubic foot of quicksilver weighing 947 pounds, whilst a cubic foot of water weighs but 70: it is found to be heavier in winter than in summer, in the proportion of eleven ounces thirty-two grains, to eleven ounces seven grains. In consequence of its great density, it is of all fluids the coldest to the touch: the hand cannot

cannot be kept one quarter of an hour in a quantity of quicksilver with safety. Of all fluids likewise it grows the hottest, not really, but apparently, from the application of an equal external heat.

In a heat below ignition, it totally exhales in extremely thin, subtle, penetrating fumes, which condense into running mercury again: the admission of air, which changes the fumes of the other semi-metals into a powdery calx, has not that effect upon those of quicksilver.

It dissolves in all the mineral acids, but with different degrees of facility; and proves itself a menstruum for sundry metallic bodies. It has the greatest affinity with gold; adhering to, and dissolving that metal the most readily of all. It unites easily also with silver; less easily with lead; still less so with tin; very difficultly with copper; most difficultly of all with iron; to which it seems to have an insuperable repugnance. It does not easily take up bismuth or regulus of antimony, unless they are previously mingled with other metals, or disposed to unite with it by particular managements; after it has been combined with either of these, it throws them out again upon digestion; bismuth, nevertheless, disposes some other metals, particularly lead, to such an intimate union with mercury, as to pass along with it through the pores of leather. Quicksilver mingles also with various saline substances, and with sulphur; with which last it forms a black mass called *æthiops*, which changes, on sublimation, into a red one called *cinnabar*.

There are different methods of purifying quicksilver; as straining through leather; trituration or ablution with vinegar; with vinegar and salt; with soap-leys, with rectified spirit of wine, and with aqua-fortis; and distillation, either without addition, or with alkaline salts, quick-lime, or iron filings. When quicksilver is only superficially mixed with dust or earthy powders, straining through leather is sufficient for its purification: if any foulness still remains, spirit of wine will wash it off: unctuous or oily impurities require ablution with soap-leys. Lead and bismuth are most effectually separated by making the mercury into an *æthiops*, with a sufficient quantity of sulphur, and reviving it again from the *æthiops* by distillation, with twice its quantity of quick-lime, alkaline salt, or iron filings; the mercury alone will distil, and leave all its impurities behind; sulphureous, antimonial, and other like admixtures, are to be separated by the same means. The purification by aqua-fortis is performed by taking only a small quantity of the acid to a large one of mercury; grinding them diligently together, and then washing the quicksilver with water. When mercury is combined with sulphur into *cinnabar*, the revivification of it does not well succeed with alkaline salts; by fixed alkalies, the sulphur is very difficultly, and not perfectly absorbed; to volatile alkalies it does not yield at all:

on the other hand it is observable, that metallic bodies, as iron, lead, tin, regulus of antimony, readily detain the sulphur in distillation, and suffer the mercury to arise pure.

The largest quantities of mercury are employed for metallurgical operations: gold and silver are extracted, in the Spanish West-Indies, from their ores or matrices, by amalgamation with mercury; and both metals are recovered by the same means, when blended in minute particles with earthy matters, as filing or working them. Amalgamated with tin, it makes the foil for looking-glasses, and reflecting balls. It is used also for gilding on silver, for anatomical injections, for weather-glasses, and sundry other purposes. In vacuo, it appears luminous, and is then called the mercurial phosphorus.

Quicksilver, considered as a medicine, is a specific against the venereal disease, worms, lice, and all kinds of insects: the venereal distemper is not perhaps to be radically cured without it; but against insects there are other remedies equally if not more effectual. It is commonly supposed to have, of itself, no poisonous quality; but it appears by experience, manifestly prejudicial to the nerves and the bones. Its ill effects are most observable in those who are exposed to its fumes; which fumes are no other than perfect quicksilver, as any one may be convinced by receiving them on a piece of moist leather or cloth, upon which they will reunite into little globules of mercury. Most people admit a pernicious quality in the fumes, though they deny it to the quicksilver; not considering that the fumes are only the quicksilver itself, divided but not altered by the heat. Even mercurial ointments applied externally have occasioned contractions of the limbs, corrosions of the bones, and other dangerous consequences. How soon do the miners feel its effects, though they neither anoint with it, nor swallow it, nor are exposed to the fumes into which it is resolved by fire! They first become paralytic, and fall afterwards into a savivation: their teeth drop out: violent pains in the whole body, particularly in the bones, and at length death, succeed. It may be proper to observe, that the Spanish physicians treat these patients in a different method from that pursued among us and in other countries: they expose them frequently for a considerable length of time to the open air, and give internally nothing but absorbents.

Quicksilver, included in a flat-bottomed glass, having a small hole open to the air, and kept for several months in a constant heat just not strong enough to make it evaporate, calcines by degrees into a red powder, called *mercurius calcinatus*. A greater heat, sufficient to make the mercury distil, does not only promote the calcination, but revives such part as has been already calcined, into running mercury again. A weaker heat, as that of the human body, or even of boiling water, though con-

tinued

tinued for years, changes only a small part of the mercury into a blackish powder: constant triture or agitation produces similar effects to this low degree of heat, and in a much shorter time. If the free access of air should be found to influence the calcination of this, as it does that of the metallic bodies called imperfect, the tedious process might be expedited, by using, for the vessel, a glass tube, with both its ends bent upwards, and one of them considerably higher than the other; through which, a constant stream of fresh air would pass over the surface of the small thread of mercury at the bottom.

This red powder has by some been greatly esteemed in venereal cases, and supposed to be the most effectual and certain of the mercurials. It is accompanied with one considerable inconvenience, being greatly disposed to irritate the first passages, and occasion gripes; to prevent which, a small quantity of opium, and some warm aromatic material, are commonly joined to it: the antivenereal pills of a late celebrated empyric are supposed to have been a composition of this kind. Even when thus corrected, however, it does not appear to have any advantage above the mercurials in common use and of easier preparation. The dose is from half a grain to two grains: five or six grains are said to vomit and purge violently.

The blackish powder, obtained by long agitation, is the basis of an antivenereal medicine, which has lately come into great repute abroad; but which appears, from the accounts published of it in France, to be neither so safe, nor so effectual, as some of the common officinal mercurials.

If oil of vitriol be poured on half, or equal, its weight of quicksilver, and gradually heated till the liquor boils and distils; the more phlegmatic parts arise, while the stronger acid corrodes the mercury into a white caustic mass. On the affusion of warm water, the mass falls into powder, and becomes immediately yellow; a part of it, satiated with acid, dissolving in the water: the larger the quantity of acid made use of, and the less thoroughly the matter has been exsiccated or calcined, the more of it will dissolve. The yellow powder, ground with fresh quantities of water till all the soluble part is extracted, becomes insipid, and in this state, commonly called turpeth or turbith mineral, it proves, though not corrosive, strongly emetic; operating, in this intention, the most effectually of all the mercurials that can be given with safety. It is used chiefly in violent gonorrhœas, and other venereal cases accompanied with a great flux of humours to the parts: it is said likewise to have been employed with success, in robust constitutions, against leprous disorders, and obstinate glandular obstructions. The dose, as an emetic, is from two grains to six or eight; though some constitutions, habituated to mercurials, can bear larger quantities. It may be

given in smaller doses, as half a grain or a grain, as an alterative, after the same manner as the red calx of mercury already mentioned: and even when intended as an evacuant, it may perhaps, as Malouin observes, be most adviseable to give only a small quantity at a time, as one grain, and repeat this dose every hour till the vomiting succeeds.

On adding a solution of sea-salt to a solution of mercury made in aqua-fortis, the nitrous acid quits the mercury, and unites with the alkaline basis of the sea-salt; and at the same time, the acid of the sea-salt unites with the mercury, and forms with it a compound, difficultly, and only partially dissoluble, of which therefore great part subsides, on standing for some time, in form of a white powder. This powder, washed with fresh quantities of hot water, till the more soluble parts are extracted, becomes nearly insipid. In this state it is recommended by Boerhaave as one of the best of the mercurials, and said, in doses of three grains, to purge and vomit gently. It appears, however, too corrosive for internal use; being so much so, as to be employed by the farriers for the purposes of an escharotic. The preparation is likewise a very unfrugal one, a considerable part of the mercury remaining unprecipitated, and a considerable part of the precipitate being dissolved and carried off in the ablutation.

Spirit of sal ammoniac, or other volatile alkalies, dropped into a filtered solution of sublimate, absorb a part of the acid; and the mercury, retaining so little as to be indissoluble, renders the liquor milky, and subsides on standing, in form of a fine white powder, which, washed by repeated affusions of hot water, becomes insipid. Solutions of fixed alkaline salts, substituted to the volatile spirit, produce a yellow precipitation; but if an equal weight of crude sal ammoniac be dissolved along with the sublimate, fixed alkalies, added to this solution, extricate the volatile alkali of the sal ammoniac, and the precipitate proves the same as if the volatile alkali alone had been added in its pure state. These precipitates are used chiefly on account of the elegance of their colour, in unguents for cutaneous eruptions; one part of the mercurial precipitate, three of precipitate sulphur, and eighteen of the simple ointment or pomatum, moistened with a little strong alkaline ley, make the common mercurial application for these complaints. The precipitates have been given internally; but mercurius dulcis, which differs from them only in being more mild, and more equal and certain in its effects, is in this intention greatly to be preferred. It does not appear that a combination of mercury, with so small a proportion of acid, that is, so mild and safe a mercurial, can be obtained by any kind of precipitation, as by the process by which mercurius dulcis is prepared.

Mercurius dulcis is sublimate made mild, by combining

binning with it so much fresh mercury, as is sufficient to satiate the redundant acid. Four parts of powdered sublimate are ground with three of quicksilver, an operation in which great caution is necessary, to avoid the lighter corrosive particles that fly off, till they are thoroughly incorporated; or, which is much more commodious, digested together in a gentle heat, by which the union will be performed as effectually. The mixture is then sublimed in a glass matrafs or phial; the sublimed mass freed from the whitish acrid matter about the mouth of the vessel, and from such mercurial globules as may happen to appear distinct, then pulverised, and sublimed again: in this manner the sublimation is repeated six times, by which means the medicine becomes less liable to irritate the first passages, and run off by stool.

*Mercurius dulcis* seems to be the best and safest of the mercurial preparations that can be taken in a solid form. It may be given from fifteen to twenty-five grains; or, as an alterative, from one to two or three grains.

MERCURY,  $\S$ , in astronomy, the smallest of the planets, and the nearest the sun. See the article COPERNICAN.

Its mean distance from the sun is 387 of such parts of which the earth is 1000, its excentricity is 80 of such parts. The inclination of its orbit is  $6^{\circ} 54'$ ; it performs its revolution round the sun in 87 days, 23 hours, 16'; its greatest elongation is about  $22^{\circ} 46'$ . The place, in the ecliptic for the ascending node is in  $14^{\circ} 42'$  of taurus. Its diameter to that of the earth is as 3 to 4; and therefore the globe of mercury will be to that of the earth as 2 to 5.

Mercury, in the same manner as venus, always keeps himself in the neighbourhood of the sun, and never recedes from him so far as venus does; he hides himself so much in the splendor of the sun's rays, that he is but seldom seen by us on the earth: but since the invention of telescopes, he has been frequently observed when in conjunction with the sun, and to pass under his disk like a black spot. The exceeding brightness by which mercury outshines all the planets, does evidently prove him to be much nearer the sun than any of the rest; for the nearer any body is to the sun, the greatest illustration it receives from him. From all this, it is evident, that mercury does likewise go round the sun in a lesser orbit, included within the orbit of venus. See the article VENUS.

MERCURY, in heraldry, a term used, in blazoning by planets, for the purple colour, in the arms of sovereign princes. See the article BLAZONING.

MERIDIAN, in astronomy, a great circle passing through the poles of the world, and both the zenith and nadir, crosseth the equinoctial at right-angles, and divideth the sphere into two hemispheres, the eastern and western: it has its poles in the east and west points of the horizon. It is called meri-

dian, because when the sun cometh to the fourth part of this circle, it is then mid-day; and then the sun has his greatest altitude for that day. These meridians are various, and change according to the longitudes of places; so that they may be said to be infinite in number, for all places from east to west have their several meridians: but there is (or should be) one fixed, which is called the first meridian. Ptolemy chose to make that the first meridian which passes near the Fortunate islands, at about the distance of one degree from them; and reckons from thence to the east through Africa and Asia; choosing to begin at a place inhabited, and which was then the bounds and limits of the known part of the earth to the west, and to end at the eastern shore of Scain in Asia.

But our geographers and map-makers frequently assume the meridian of the place, or the capital of the country, for the first meridian; and thence reckon the longitudes of their places.

MERIDIAN *Line*, on a dial, is a right-line arising from the intersection of the meridian of the place, with the plane of the dial: this is the line of twelve o'clock, and from hence the division of the hour-lines begins. See DIAL.

*Magnetical* MERIDIAN, is a great circle passing through the magnetical poles, to which the magnetic needle, or needle of the mariner's compass, conforms itself.

MERIDIAN *Altitude of the Sun or Stars*, is their altitude when in the meridian of the place where they are observed. Or it may be defined, an arch of the great circle perpendicular to the horizon, and comprehended between the horizon and the sun or star, then in the meridian of the place.

MERIDIONAL DISTANCE, in navigation, is the same with the departure, easting or westing, or the difference of longitude between the meridian under which the ship now is, and any other meridian she was before under.

MERIDIONAL *Parts, Miles, or Minutes*, in navigation, are the parts by which the meridians in Mr. Wright's Chart (commonly, though falsely, called Mercator's) do increase as the parallels of latitude decrease: and as the cosine of the latitude of any place, is equal to the radius or semi-diameter of that parallel; therefore, in the true sea-chart, or nautical planisphere, this radius being the radius of the equinoctial, or whole sine of  $90^{\circ}$ , the meridional parts at each degree of latitude must increase, as the secants of the arch, contained between that latitude and the equinoctial, do decrease. The tables, therefore, of meridional parts, which we have in books of navigation, are made by a continual addition of secants; they are calculated in some books for every degree and minute of latitude; and they will serve either to make or graduate a Mercator's Chart, or to work the Mercator's Sailing.

MERLON, in fortification, is that part of a parapet

rapet which is terminated by two embrasures of a battery. Its height and thickness is the same with that of the parapet; but its breadth is generally nine feet on the inside, and six on the outside. It serves to cover those on the battery from the enemy; and is better when made of earth well beat and close, than when built with stone; because these fly about and wound those they should defend.

MERLUCIUS, in ichthyology, a fish called in English the hake. See HAKE.

MERMAID, or MERMAN, an imaginary animal, supposed to be half human and half fish; which probably took its rise from an imperfect view of the thrichechus. See THRICHECHUS.

MEROPS, the BEE-EATER, in ornithology, the blue-breasted ispida, with a variegated head; a very beautiful bird, somewhat larger than the common king-fisher. See ISPIDA.

MERULA, the BLACKBIRD, in ornithology, a species of the turdus or thrush-kind. See the article TURDUS.

MESEMBRYANTHEMUM, fig-marigold, in botany, a genus of plants, whose flower is monopetalous and cut into many spear-shaped linear segments, and ranged in several series: the stamina are composed of a great number of capillary filaments, terminated by incumbent antheræ: the fruit is a roundish fleshy capsule, having several cells, which are filled with small roundish seed.

There are great varieties of this genus, most of which are natives of the Cape of Good-Hope; and are preserved in our green-houses, either for the beauty of the flowers of some species, or the agreeable variety of the foliage of others: they are most of them perennial plants, and are easily raised from cuttings in the summer months.

This genus comprehends the ficoides of Tournefort.

MESENTERY, in anatomy, a thick fat membrane, placed in the midst of the intestines, particularly of the smaller ones, whence it has the name. Its substance is composed of membranes, fat, vessels of all kinds, and in the human body of a number of glands. In the upper part, it is connected with the three superior vertebræ of the loins; and in the lower, with the intestines, and particularly with the jejunum and ileum; to which it also gives their outer coat. When it is separated from the intestines, it has several folds resembling gloves. Its length, in the whole, is about three ells, but the intestines which are joined to it, are at least four times that length. Its coats or membranes are two, and between these there is a cellular substance which contains the fat: the meseraic vessels and glands are also placed there, which many reckon a third coat of the mesentery, and that not improperly; this they call the tunica cellulosa.

The vessels of the mesentery are blood-vessels,

nerves, lacteals, and lymphatics. The blood-vessels are the same with those of the intestines, and these make a multitude of strange meanders, and have very frequent anastomoses. The nerves also come from the par vagum, and the intercostals.

MESNE, in law, signifies him who is lord of a manor, and who hath tenants holding of him, yet himself holding of a superior lord. This word also signifies a writ, which lies where there is a lord-mesne and tenant, and the tenant is distrained for services due from the mesne to the superior lord.

MESCOLON, in anatomy, that part of the mesentery connected with the great guts, especially the colon. See the article MESENTERY.

The mesocolon meets the midst of the colon, to which it is joined. Its lower part sticks to a part of the rectum.

MESOLABE, an instrument used by the ancients for finding two mean proportionals mechanically, which they could not effect geometrically.

It consisted of three parallelograms, moving in a groove to certain intersections.

MESOLOGARITHMS, according to Keplar, are the logarithms of the co-sines and co-tangents, the former of which were called by lord Napier antilogarithms, and the latter differentials.

They are otherwise called artificial sines and tangents. See the articles LOGARITHM, SINE, TANGENT, &c.

MESPILUS, the medlar, in botany, a genus of plants, whose flower consists of five roundish concave petals inserted in the cup; the stamina are from ten to twenty subulated filaments, topped with single antheræ. The fruit is a globose umbilicated berry, carrying the cup on its top; and contains five osseous and gibbous seeds. This genus includes the several species of hawthorns, the glastenbury thorn, and pyracantha. The fruit of the common medlar is very grateful, though not eatable till it is rotten.

MESSIAH, the anointed; a title which the Jews gave to their expected great deliverer, whose coming they still wait for; and a name the Christians apply to Jesus Christ, in whom the prophecies relating to the Messiah were accomplished. Among the Jews, anointing was the ceremony of consecrating persons to the highest offices and dignities; kings, priests, and sometimes prophets, were anointed: thus Aaron and his son received the sacerdotal, Elisha the prophetic, and David, Solomon, and others, the royal unction.

METACARPUS, in anatomy, that part of the hand between the wrist and the fingers.

METACARPUS, signifies also a small, very fleshy muscle, situated obliquely between the large internal annular or transverse ligament of the carpus, and the whole inside of the fourth metacarpal bone.

METAGITNION, *μεταγειτνια*, in chronology, the

the second month of the Athenian year, containing twenty-nine days, and answering to the latter part of our July, and beginning of August.

**METALS**, *metalla*, in natural history, are defined to be fossile bodies, fusible by fire, concreting again in the cold, and malleable, or distensible and ductile under the hammer. These are the distinguishing characters of these bodies in their pure state: but many of them are not found in this pure state in the earth, being reduced by admixtures of sulphur and other bodies to the state of ore. See **ORE**. The class of the metals, according to these characters, include six bodies, viz. gold, silver, copper, tin, iron, and lead. For the properties, preparations, uses, and peculiar characters, &c. of each, see the articles **GOLD**, **SILVER**, &c.

*Prince's METAL*, called also *Bath-METAL*, a kind of factitious metal, of a beautiful yellow, and disposed to receive a fine polish, lustre, &c. It is prepared, according to Dr. Shaw, as follows: take six ounces of copper, melting it in a wind-furnace; add to it one ounce of zink: then stirring the whole well together, pour out the metal immediately. The copper and zink may be put into the crucible together, if first covered over with the black flux, which prevents the evolution of the zink, or preserves its metalline form. See the article **FLUX**.

*Semi-METALS*, metallic fossils, fusible by fire, and not malleable in their purest state.

These are all, in their native state, penetrated by, and intimately mixed with sulphur, and other adventitious matter, and reduced to what are called ores.

Of this series of fossils there are only five bodies, all naturally comprehended in the same class, but each making a separate and distinct genus: these are antimony, bismuth, cobalt, zink, and quicksilver. For the characters, preparations, and uses of each, see **ANTIMONY**, **BISMUTH**, **COBALT**, **ZINK**, and **MERCURY**.

**METAL**, in heraldry. There are two metals used in heraldry, by way of colours, viz. gold and silver, in blazon called *or* and *argent*.

In the common painting of arms these metals are represented by white and yellow, which are the natural colours of those metals. In engraving, gold is expressed by dotting the coat, &c. all over; and silver, by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour upon colour; so that if the field be of one of the metals, the bearing must be of some colour; and if the field be of any colour, the bearing must be of one of the metals.

**METALLIC**, or **METALLINE**, an adjective applied to something that bears a relation to metals. See **METAL**.

**METALLURGY**, *metallurgia*, according to Boerhaave, comprehends the whole art of preparing and working metals, from the glebe, or ore, to the

utenfil; in which sense, assaying, smelting, refining, smithery, gilding, &c. are only branches of metallurgy.

**METAMORPHOSIS**, in general, denotes the changing of something into a different form; in which sense it includes the transformation of insects, as well as the mythological changes related by the ancient poets.

Mythological metamorphoses were held to be of two kinds, apparent and real: thus that of Jupiter into a bull, was only apparent; whereas that of Lycaon into a wolf, was supposed to be real.

Most of the ancient metamorphoses include some allegorical meaning, relating either to physics or morality: some authors are even of opinion that a great part of the ancient philosophy is couched under them; and lord Bacon and Dr. Hook have attempted to unriddle several of them.

Ovid's Metamorphoses make an excellent system of morality: the stories of Deucalion and Pyrrha, of Phæton, of Baucis and Philemon, of Minos and Scylla, &c. being excellent lessons in this way.

**METAPHOR**, in rhetoric, a trope, by which we put a strange word for a proper word, by reason of its resemblance to it; or it may be defined, a simile or comparison intended to enforce or illustrate the thing we speak of, without the signs or forms of comparison. Thus, if we say, *God is a shield to good men*, it is a metaphor, because the sign of comparison is not expressed, though the resemblance which is the foundation of the trope, is plain; for as a shield guards him that bears it, against the attacks of an enemy, so the providence and favour of God protects good men from malice and misfortunes: but if the sentence be put thus, *God is as a shield to good men*, then it becomes a simile or comparison.

**METAPHRASE**, usually signifies something more than either a translation or a paraphrase: according to Baillet, a metaphrast implies a translator, glossator, and interpolator altogether.

**METAPHYSICS**, *Metaphysica Transnaturalis*, ontology, or ontosophy, a science that treats of being, as such, in the abstract.

**METAPLASMUS**, in grammar, a transmutation or change made in a word, by adding, retrenching, or altering a letter or syllable thereof.

The several species of this figure are ten in number, viz. prosthesis, epenthesis, paragoge, diæresis, aphæresis, syncope, apocope, crasis, metathesis and antithesis; four of which augment the letters or syllables of a word, four retrench them, and two alter them.

**METASTASIS**, in medicine, a transposition or settlement of some humour or disease, on some other part; and sometimes it signifies such an alteration of a disease, as is succeeded by a solution.

**METATARSUS**, in anatomy, a fleshy mass lying under the sole of the foot.

**METATHESIS**, in grammar, a species of the metaplasmus; being a figure whereby the letters or syllables of a word are transposed, or shifted out of their usual situation, as *pistris* for *pristis*, *lybia* for *libya*, &c.

**METEMPSYCHOSIS**, the doctrine of transmigration, which supposes that human souls, upon their leaving the body, become the souls of such kind of brutes as they most resemble in their manners.

This was the doctrine of Pythagoras and his followers, who held that the souls of vicious men were imprisoned in the bodies of miserable beasts, there to do penance for several ages, at the expiration whereof they returned again to animate men; but if they had lived virtuously, some happier brute, or even a human creature, was to be their lot. What led Pythagoras into this opinion was the persuasion he had that the soul was not of a perishable nature; whence he concluded, that it must move into some other body upon its abandoning this. Lucan thinks this doctrine was contrived to mitigate the apprehension of death, by persuading men that they only changed their lodgings, and ceased to live only to begin a new life. Reuchlin denies this doctrine, and maintains, that the metempsychosis of Pythagoras implied nothing more than a similitude of manners and desires formerly existing in some person deceased, and now reviving in another alive. Pythagoras is said to have borrowed the notion of a metempsychosis from the Egyptians; others say from the antient brachmans. It is still retained among the antient Banians, and other idolaters of India and China, and makes the principal foundation of their religion. Many of the modern Jews are said to espouse this doctrine, and, to support their opinion, quote these words of Job, "Lo all these things worketh God oftentimes with man (in Hebrew, *and thrice*) to bring back his soul from the pit to be enlightened with the light of the living." It is certain, that at the time of Jesus Christ this opinion was very common among the Jews: this appears in the Gospel, when they say that some thought Jesus Christ to be John the Baptist, others Elias, others Jeremiah, &c.

**METEMTOSIS**, a term in chronology, expressing the solar equation, necessary to prevent the new moon from happening a day too late, by which it is opposed to proemptions, which signifies the lunar equation necessary to prevent the new moon from happening a day too soon.

**METEOR**, in physiology, an imperfect, changeable, and mixt body, or the resemblance of a body appearing in the atmosphere, and formed by the action of the heavenly bodies, out of the common elements.

**METHOD**, *metodos*, in logic, &c. the arrangement of our ideas in such a regular order, that their

mutual connection and dependence may be readily comprehended. See **IDEA** and **KNOWLEDGE**.

**METHODISTS**, a name at first given to a society of religious young men at Oxford, and now applied to all those who adhere to the doctrine of the church of England as taught by Whitefield, Wesley, &c.

**METHODISTS**, *Methodici*, is also an appellation given a sect of ancient physicians, who reduced the whole healing art to a few common principles or appearances.

**METOCHE**, in ancient architecture, a term used by Vitruvius to signify the space or interval between the dentils.

**METONIC CICLE**, in chronology, the same with the cycle of the moon. See **CYCLE**.

**METONYMY**, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them.

**METOPE**, *Metopa*, in architecture, is the interval or square space between the triglyphs of the Doric frieze, which, among the ancients, used to be painted or adorned with carved work, representing the heads of oxen, or utensils used in sacrifices.

**Semi-METOPE**, in architecture, is a space in the corner of the Doric frieze, somewhat less than half a metope.

**METOPOSCOPY**, the pretended art of knowing a persons dispositions and manners, by viewing the traces and lines in the face. See **PHYSIOGNOMONICS**.

**METRE**, *μετρα*, in poetry, a system of feet of a just length. See **NUMBERS**.

**METRETES**, an ancient measure of capacity, containing a little more than nine gallons.

**METRICAL**, something relating to metre.

**METROPOLIS**, the capital or principal city of a country or province.

**MEUM**, spiguel, in botany. See **SPIGUEL**.

**MEW**, a place where a hawk is set, during the time she raises her feathers.

**MEWING**, the falling off, or change of hair, feathers, skin, horns, or other parts of animals, which in some happens annually, in others only at certain stages of their lives: but the generality of beasts mew in the spring.

**MEZEREON**, in botany, a shrub common in our gardens; the flowers come out very early in the spring, before the leaves appear, growing in clusters all round the shoots of the former year; there are commonly three flowers produced from each knot or joint standing on a short foot-stalk: when the flowers are decayed, they are succeeded by smooth spear-shaped leaves, about two inches long, which are irregularly placed on the branches: the fruit is an oval berry, which ripens in June.

The mezereon is propagated by sowing the seeds soon after they are ripe; and when the plants have

remained two years in the seed bed, they may, in autumn, be transplanted into the nursery, there to remain two years more, at which time they may be planted where they are intended to remain.

Although the birds are very fond of the berries of this plant, when they are ripe, yet they are so very acrid as to burn the mouths and throats of those persons who incautiously taste them.

There are two sorts of mezereon, one producing white flowers with yellow berries, and the other having pink coloured flowers with red berries.

For the generical characters of mezereon, see the article DAPHNE, of which it is held a species.

MEZZOTINTO, a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink.

The manner of making mezzotintos is very different from all other kinds of engraving and etching, since instead of forming the figures with lines and scratches, made with the point of a graver, or by means of aqua-fortis, they are wholly formed by scraping and burnishing.

Mezzotintos are made in the following manner: Take a well-polished copper-plate, and beginning at the corner, rake or furrow the surface all over with a knife or instrument made for the purpose, first one way and then the other, till the whole is of a regular roughness, without the least smooth part to be seen; in which state, if a paper was to be worked off from it at the copper-plate press, it would be all over black. When this is done, the plate is rubbed over with charcoal, black-chalk, or black-lead, and then the design is drawn with white chalk; after which, the out-lines are traced out, and the plate finished by scraping off the roughness, so as to leave the figure on the plate.

The out-lines and deepest shades are not scraped at all, the next shades are scraped but little, the next more, and so on, till the shades gradually falling off, leave the paper white, in which places the plate is neatly burnished.

By an artful disposition of the shades, and different parts of a figure on different plates, mezzotintos have been printed in colours, so as nearly to represent very beautiful paintings.

MIASMA, among physicians, denotes the contagious effluvia of pestilential diseases, whereby they are communicated to people at a distance.

MICAH, or the Book of MICAH, a canonical book of the Old-Testament, written by the prophet Micah, who is the seventh of the twelve lesser prophets. He is cited by Jeremiah, and prophesied in the days of Jotham, Ahaz, and Hezekiah. He censures the reigning vices of Jerusalem and Samaria, and denounces the judgments of God against both kingdoms. He likewise foretells the confusion of the enemies of the Jews, the coming of the Messiah, and the glorious success of his church.

MICHAELMAS, or *Feast of St. MICHAEL and all Angels*, a festival of the Christian church, observed on the twenty-ninth of September.

MICHELIA, in botany, a genus of plants, whose flower consists of eighteen lanceolated petals, with many, very short, subulated filaments, topped with erect pointed antheræ: the fruit is composed of a number of globose unilocular berries, each containing four seeds, convex on one side and angulated on the other.

MICROCOSM, *μικροκοσμος*, a Greek term, signifying the little world; used by some for a man, as being supposed an epitome of the universe, or great world.

MICROGRAPHY, *μικρογραφια*, the description of objects, too minute to be viewed without the assistance of a microscope. See the article MICROSCOPE.

MICROMETER, an astronomical machine, which, by means of a screw, serves to measure extremely small distances in the heavens, &c. and that to a great degree of accuracy.

The micrometer consists of a graduated circle, (plate LXXI. *fig. 1.*) of a screw *qo*, and its index *qr*. The threads of the screw are such, that 50 make the length of one inch exactly. When it is to be used, the point *o* is set to the side of the part to be measured, and then the index is turned about with the finger, till the eye perceives the point has just passed over the diameter of the part; then the number of turns, and parts of a turn, shewn by the graduated circle, will give the dimensions in part of an inch, as we shall shew by the following example: Suppose it required to measure the diameter of an human hair, and I observe the index is turned just once round, while the point *o* passes over it. Then it is plain, the diameter of the hair in the image is  $\frac{1}{50}$  of an inch. Now, if the microscope *I DEF def*, magnifies 6 times, or makes the image 6 times larger in diameter than the object, then is the diameter of the hair itself but  $\frac{1}{6}$  of  $\frac{1}{50}$ , that is, but  $\frac{1}{300}$  part of an inch.

Also, it is to be observed, that as there are 10 large divisions and 20 small ones, on the micrometer-plate, so each of those small divisions are the  $\frac{1}{20}$  of  $\frac{1}{300}$ , or the  $\frac{1}{6000}$  part of an inch. Therefore, if, in measuring any part of an object, you observe how many of these smaller divisions are passed over by the index, you will have so many thousandth parts of an inch for the measure required. All which is so plain, that nothing can be said to illustrate the matter.

MICROPUS, bastard cudweed, in botany, an annual plant, whose root sends forth several trailing stalks, which are furnished with several small oval leaves of a bright silvery colour; whose base embraces the stalk. The flowers are female and hermaphrodite, and come out in clusters from the wings

wings of the stalks. The female flowers have neither corolla nor pericarpium, but the seeds are included in the cup, which is immutable; the hermaphrodite flowers are monopetalous and infundibuliform, but are barren.

**MICROSCOPE**, an optical instrument, by means whereof, very minute objects are represented, exceedingly enlarged, and are viewed very distinctly, according to the laws of refraction or reflection. See REFRACTION and REFLECTION.

Microscopes are either single or double; a single microscope is only a very small globule of glass, or a small double convex glass, whose focal distance is very short. A minute object  $pq$  (plate LXXI. *fig. 2.*) seen distinctly through a small glass  $AE$  by the eye put close to it, appears so much greater than it would to the naked eye, placed at the least distance  $qL$ , from whence it appears sufficiently distinct, as this latter distance  $qL$  is greater than the former  $qE$ . For having put your eye close to the glass  $EA$ , in order to see as much of the object as possible at one view, remove the object  $pq$  to and fro, till it appears most distinctly, suppose at the distance  $Eq$ . Then conceiving the glass  $AE$  to be removed, and a thin plate, with a pin-hole in it, to be put in its place, (*fig. 3.*) the object will appear distinct, and as large as before, when seen through the glass, only not so bright. And in this latter case, it appears so much greater than it does to the naked eye, at the distance  $qL$ , either with the pin-hole or without it, as the angle  $pEq$  is greater than the angle  $pLq$ , or as the latter distance  $qL$  is greater than the former  $qE$ . Since the interposition of the glass has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye. If the eye be so perfect as to see distinctly by pencils of parallel rays falling upon it, the distance,  $Eq$ , of the object from the glass, is then the focal distance of the glass. Now if the glass be a small round globule whose diameter is  $\frac{1}{15}$  of an inch, its focal distance  $Eq$  being three quarters of its diameter, is  $\frac{1}{20}$  of an inch; and if  $qL$  be eight inches, the usual distance at which we view minute objects, this globule will magnify at the rate of 8 to  $\frac{1}{20}$  or of 160 to 1.

In microscopes made with single lenses, a given object placed at their principal focuses will appear equally distinct, if their linear apertures be as their focal distances. And in microscopical lenses, whose focal distances are not much longer than half an inch, there is no need to contract their apertures, for procuring distinct vision; the pupil itself being small enough to exclude the exterior straggling rays. But in smaller lenses, where apertures are necessary, to preserve the same degree of distinctness, their diameters must be as their focal distances; and then

their apparent brightness will decrease in a duplicate ratio of their focal distances, so that by using smaller glasses the apparent magnitude and the obscurity of the object will both increase in the same ratio.

A double microscope is composed of two convex glasses placed at  $E$  and  $L$  (*fig. 4.*) The glass  $L$  next the object  $PQ$  is very small, and very much convex, and consequently its focal distance  $LF$  is very short; the distance  $LQ$  of the small object  $PQ$ , is but a little greater than  $LF$ ; so that the image  $pq$ , may be formed at a great distance from the glass, and consequently may be much greater than the object itself. This picture  $pq$  being viewed through a convex eye-glass  $AE$ , whose focal distance is  $qE$ , appears distinct. Now the object appears magnified upon two accounts; first, because if we viewed its picture  $pq$  with the naked eye, it would appear as much greater than the object; at the same distance, as it really is greater than the object, or as much as  $Lq$  is greater than  $LQ$ ; and secondly, because this picture appears magnified through the eye-glass as much as the least distance at which it can be seen distinctly with the naked eye, is greater than  $qE$ , the focal distance of the eye-glass. For example, if this latter ratio be 5 to 1, and the former ratio of  $Lq$  to  $LQ$  be 20 to 1, then upon both accounts the object will appear 5 times 20, or 100 times greater than to the naked eye.

To fit these microscopes to short-sighted eyes, the glasses  $E$  and  $L$  must be placed a little nearer together; so that the rays of each pencil may not emerge parallel, but may fall diverging upon the eye; and then the apparent magnitude will be altered a little, but scarce sensibly.

*The Solar or Camera Obscura* **MICROSCOPE**, depends on the sun-shine, and must be made use of in a darkened chamber, as its name implies. This instrument consists of several parts, viz. A (plate LXXI. *fig. 5.*) a square frame of mahogany to be fixed to the shutter of a window, by means of the screws 1, 1. To this frame is applied a circular collar of the same wood, with a groove, on its periphery on the outside, denoted by 2, 3. This collar is connected by a cat-gut to the pulley 4 on the upper part, which is turned round by the pin 9 within. On one part of the collar, on the outside, is fastened, by hinges, a looking-glass  $G$ , in a proper frame, to which is fixed the jointed wire 6, 7; by which means, and the screw  $H$  8, it may be made to stand in an angle more or less inclined to the frame. In the middle of the collar is fixed a tube of brass  $C$ , near two inches in diameter; the end of which, on the outside, has a convex lens 5 to collect the sun-beams thrown on it by the glass  $G$ , and converging them towards a focus in the other part, where  $D$  is a tube sliding in and out to adjust the object to a due distance from the focus. To the end  $G$  of another tube  $F$ , is screwed one of Wilson's

Fig. 1. Micrometer.

Fig. 7. Mirrour.

Fig. 9.

Fig. 6.

Fig. 4. Double Microscope.

Fig. 2. Single Microscope.

Fig. 3.

Willson's single pocket-microscopes, containing the object to be magnified in a slider; and by the tube F, sliding on the small end E of the tube D, it is brought to a due focal distance.

The sun's rays being directed by the looking-glass through the tube upon the object, the image or picture of the object is thrown distinctly and beautifully upon a screen of white paper, or a white linen sheet, placed at some distance to receive the same; and may be magnified to a size beyond the imagination of those who have not seen it. For the farther off the screen is removed, the larger will the object appear, inasmuch that a louse may be magnified to the length of five or six feet, or even a great deal more; but it is more distinct when not enlarged to above half that size.

This instrument has been contrived very commodiously in several different forms; but we shall here illustrate the following by a diagram. AR (fig. 6.) is a section of the window-shutter of a dark room, CD of the frame containing a scioptric ball EF; in the forepart whereof is screwed the tube GIKH, at one end of which is a lens GH, which, by converging the sun-beams into a narrow compass, does strongly enlighten the small object *ab*, placed on a slip of glass, or otherwise, in the part of the tube NQ, where a slit is made on each side for that purpose. Within this tube there slides another, LmrM, which contains a small magnifying lens *mr*. By moving the exterior tube, IGHK, one way and the other, the glass GH will be brought to receive the rays of the sun directly, and will therefore most intensely illuminate the object *ab*. The other tube, LM, being slid backwards and forwards, will adjust the distance of the smaller lens *mr*, so that the image of the object *ab* shall be made very distinct, on the opposite side of the room at OP; and the magnitude of the image will be to that of the object, as its distance from the lens *mr* is to the distance of the object from it, as is evident from the figure.

Thus, for example, suppose the focal distance of the lens *mr* to be one inch = *r*, and let the distance at which it is placed from the object be *i*,  $i = d$ ; then, if the lens be double and equally convex, as usual, the distance of the image will be  $\frac{dr}{d-r} = f = 110$ ; therefore the image will be 110 times larger than the object in its linear dimensions, and  $110 \times 110 = 12100$  times larger in surface; and in solidity it will  $110 \times 110 \times 110 = 1331000$  times larger than the object.

This is the most entertaining of any; and, perhaps, the most capable of making discoveries in objects that are too opaque, as it shews them much larger than can be done any other way. Such too as have no skill in drawing, may, by this contrivance, easily sketch out the exact figure of any object they have a mind to preserve a picture of.

MID-HEAVEN, the point of the ecliptic that culminates, or in which it cuts the meridian.

MIGNONETTE, in botany, a species of the *reseda*. See the article RESEDA.

MILIUM, millet, in botany. See the article MILLET.

MILDEW, *rubigo*, a disease happening to plants, caused by a dewy moisture, supposed by some to be a species of blight. See the article BLIGHT.

MILE, *mille passus*, a measure of length or distance, containing eight furlongs, &c. See the article MEASURE.

The English statute mile is fourscore chains, or 1760 yards; that is, 5280 feet.

We shall here give a table of the miles in use among the principle nations of Europe, in geometrical paces, 60,000 of which make a degree of the equator.

|                              | Geometrical paces. |
|------------------------------|--------------------|
| Mile of Russia               | 750                |
| of Italy                     | 1000               |
| of England                   | 1250               |
| of Scotland and Ireland      | 1500               |
| Old league of France         | 1500               |
| The small league, <i>ib.</i> | 2000               |
| The mean league, <i>ib.</i>  | 2500               |
| The great league of France   | 3000               |
| Mile of Poland               | 3000               |
| of Spain                     | 3248               |
| of Germany                   | 4000               |
| of Sweden                    | 5000               |
| of Denmark                   | 5000               |
| of Hungary                   | 6000               |

MILIARY-FEVER, a malignant fever, so called from the eruption of certain pustules resembling millet-seeds.

MILITARY, something belonging to the soldiery or militia.

MILITARY ARCHITECTURE, the same with fortification. See FORTIFICATION.

MILITARY ART, the science or art of making or sustaining war to advantage.

MILITARY WAYS, *Via Militares*, the large Roman roads which Agrippa procured to be made through the empire in Augustus's time, for the marching of troops and conveying of carriages. These were paved from the gates of Rome, to the utmost limits of the empire. See ROAD.

MILITIA, in general, denotes the body of soldiers, or those who make profession of arms.

In a more restrained sense, militia denotes the trained bands of a town or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or stated troops.

MILK, *Lac*, a well known animal fluid, which nature prepares in the breasts of women, and the udders of other animals, for the nourishment of their young. Milk, according to Boerhaave, is a liquor

prepared from the aliment chewed in the mouth, digested in the stomach, perfected by the force and juices of the intestines, and elaborated by means of the mesentery and its gland and juices, and the juices of the thoracic duct. It has undergone some actions of the veins, arteries, heart, lungs, and juices, and began to be assimilated; yet may still be had separate and discharged out of the body. And thus by their own milk, prepared from the proper matter of the chyle, all the known lactiferous animals are nourished, both male and female. For milk is always prepared from chyle as well in men as in women, in virgins and barren women, in mothers and nurses. Whence every such animal consists, is nourished, and lives on its own proper milk; and from this alone prepares all the other parts, both the solid and fluid, by means of the vital actions. It is also certain that many live for years by feeding on milk alone, and perform all the actions of life, and have all the solid and fluid parts of their bodies perfectly elaborated: the serum, therefore, the blood, the lymph, the spirits, bones, cartilages, membranes, and vessels, proceed from milk; and milk must contain in itself the matter of all the parts of the human body.

MILK of Sulphur. See SULPHUR.

MILK-VETCH, *Astragalus*, in botany. See ASTRAGALUS.

MILK-WORT, *Polygala*, in botany. See POLYGALA.

MILL, a machine or engine for grinding corn, &c. of which there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c.

In water-mills the momentum of the water is the moving power, and the attrition of the two stones in grinding, is the force to be overcome. Of these there are two kinds, viz. those where the force of the water is applied above the wheel, and those where it is applied below the wheel; the former being called over-shot, and the latter under-shot mills; and to these we may add a breast-mill; where the water strikes against the middle of the wheel.

MILLEFOLIUM, yarrow, in botany. See the article ACHILLEA.

MILLENARIANS, or CHILIASTS, a name given to those, who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years. The former appellation is of latin original, the latter of Greek, and both of the same import.

The millenarians held that after the coming of antichrist, and the destruction of all nations, which shall follow, there shall be a first resurrection of the just alone: that all who shall be found upon earth, both good and bad shall continue alive; the good, to obey the just who are risen, as their princes; the

bad, to be conquered by the just, and to be subject to them: that Jesus Christ will then descend from heaven in his glory: that the city of Jerusalem will be rebuilt, enlarged, embellished, and its gates stand open night and day. They applied to this new Jerusalem, what is said in the Apocalypse, ch. xxi. and to the temple, all that is written in Ezekiel xxxvi. Here they pretended Jesus Christ will fix the seat of his empire, and reign a thousand years with the saints, patriarchs and prophets, who will enjoy perfect and uninterrupted felicity.

This reign of our Saviour on earth is usually styled the millenium, or reign of a thousand years.

MILLEPES, the common WOOD-LOUSE, a species of the oniscus with a blunt forked tail.

MILLERIA, in botany, a genus of plants, whose flowers are compounded and radiated, consisting of several hermaphrodite and female corollulæ; the hermaphrodite are monopetalous, tubulose, and quinque-dentated; and the female are ligulated, obtuse, concave, and emarginated; there is scarce any visible receptacle for the seeds, which are single, without down, and produced only from the female florets.

MILLET, *millium*, in botany, a genus of plants, of the gramineous kind, the flower cup of which is a bivalvular glume, the corolla is less than the cup, and is also bivalvular; it has three very short capillary filaments terminated by oblong antheræ: the seeds are roundish and covered by the corolla.

The seeds of millet are much used as a common aliment in the eastern countries, where they boil it in milk, it having the same virtues as rice: they are accounted drying, and recommended in fluxes; they are also said to promote sweat and urine very powerfully.

MILLING, in the manufacture of cloth, the same with fulling. See FULLING.

Milling of silk, is an operation otherwise called throwing.

MILLION, in arithmetic, the number of ten hundred thousand, or a thousand times a thousand.

MILVUS, the kite, in ornithology, a species of falcon, with a forked tail, a yellow cere, a brown body, and a whitish head. It is a very common bird with us, about the size of a large tame pigeon.

MIME, *μιμος*, in the antient comedy, a person who acted any character by mere gestures, and hence denominated pantomime. See the article PANTOMIME.

MIMESIS, *μιμησις*, in rhetoric, the imitating the voice and gestures of another person.

MIMOSA, the sensitive plant, in botany, a genus, whose flower has a single small infundibuliform corolla, lightly cut at the extremity into five parts; the stamina are a number of long hairy filaments,

terminated with incumbent antheræ; the fruit is a long articulated pod, containing several compressed roundish seeds.

To this genus Linnæus has added the acacia of Tournefort, and the inga of Plumier.

There are several species of the mimosa, but the sensitive plant, or humble plant (so denominated from its remarkable property of receding from the touch, and giving signs as it were of animal life and sensation, which has hitherto not been accounted for) performs its motions by means of two distinct articulations; that is, either by touching the leaves lightly they then contract themselves together, and if the motion wherewith the plant is moved be strong, then the leaves not only contract but the footstalk which supports them also declines from that part of it which connects with the branch, as though it were fasted to it by a kind of hinge; when the leaves are thus struck, the whole plant appears as though it were withered, like others which happen to be transplanted in very hot weather; but it may be remarked, that these plants are more susceptible of the touch in very warm weather than when it is cool, and in about ten minutes or a quarter of an hour the leaves expand again.

The sensitive plant being a native of the West Indies, it therefore requires a hot-house in this climate: they are commonly propagated from seeds, which should be sown in the spring upon a hot bed; in about three weeks after the plants are come up they should be transplanted singly into small pots, and plunged in a fresh hot bed, and afterward when summer is come on may be removed into a hot-house; or where that conveniency is wanting, they may be kept under a common glass light, it being necessary to protect them from the open air, not only on account of their tenderness, but also to keep their leaves expanded; in the hot-house they may be kept the winter, and the following summer they will flower and perfect their seeds.

MIMULUS, in botany, a genus of plants, whose flower is monopetalous and ringent, the tube is the length of the cup, and the limb is bilabiated: the stamina are four slender filaments, topped with bifid reniform antheræ. The fruit is an oval bilocular capsule, containing many small seeds.

MIMUSOPS, in botany, a genus of plants, whose flower contains eight lanceolated patent petals, with eight very short pilose filaments, topped with erect oblong antheræ. The fruit is an oval acuminate drupe, inclosing one or two oval seeds.

MINA, in Grecian antiquity, a money of account, equal to an hundred drachms. See MONEY and DRACHM.

MINCIO, or MENZO, a river of Italy, which, after running through the dutchy of Mantua discharges itself into the Po, at Borgoforte.

MIND, *mens*, *mens*, a thinking intelligent being, otherwise called spirit, in opposition to matter or body. See the articles BODY and SPIRIT.

MINE, in natural history, a place under ground, where metals, minerals, or even precious stones are dug up.

MINE, in the military art, denotes a subterraneous canal, or passage, dug under the wall or rampart of a fortification, intended to be blown up by gun-powder.

MINERAL, in natural history, is used, in general, for all fossil bodies, whether simple or compound, dug out of a subterraneous mine, from which it takes its denomination.

MINERAL Waters, in medicine, all those wherein any medicinal virtue, besides those of common water, are found.

These mineral waters are of various kinds, but they are considered under the general titles of chalybeate, purgative, and alterative.

MINERVALIA, in Roman antiquity, festivals celebrated in honour of Minerva, in the month of March; at which time the scholars had a vacation, and usually made a present to their masters, called from this festival minerval.

These festivals were otherwise called quinquatria, from their lasting five days. See the article QUINQUATRIA.

MINHO, a great river of Spain, which, taking its rise in Galicia, divides that province from Portugal, and falls into the Atlantic at Caminha.

MINIATURE, a delicate kind of painting, distinguished from all others by the smallness of the figures, it being performed with dots or points, instead of lines; by the faintness of the colouring; its requiring to be viewed very near; and by its being usually done on vellum.

This is the nicest and most tedious of all kinds of painting, being performed wholly with the point of the pencil: for when the colours are laid on flat without dotting, though the figures be small, and the ground either vellum or paper, it is not called painting in miniature, but washing.

MINIM, in music, a note equal to two crotchets, or half a semibreve.

MINIMS, a religious order in the church of Rome, founded by St. Francis de Paula, towards the end of the fifteenth century. Their habit is a coarse black woollen stuff, with a woollen girdle of the same colour, tied in five knots. They are not permitted to quit their habit and girdle night or day. Formerly they went bare-footed, but are now allowed the use of shoes.

MINIMUM, in the higher geometry, the least quantity attainable in a given case. See the article MAXIMUM.

MINION, a piece of cannon, at present but little

little used in the field. For its length bore, and the weight of the ball it carries, see CANNON.

MINIUM, or RED-LEAD, a preparation of lead used both in pharmacy and painting. It is made in the following manner: melt lead in a broad earthen vessel unglazed, and stir it continually with a spatula till it be calcined into a grey powder; this is called the calx of lead: continue the fire, stirring it in the same manner, and it becomes yellow; in this state it is called masticot: after this put it into a reverberatory furnace, and it will calcine farther, and become of a fine red, which is the common minium or red-lead. Minium is used externally on many occasions. It obtunds the acrimony of the humours, allays inflammations, and is excellent in cleansing and healing old ulcers; and on these occasions, it is used in many of the plasters and ointments of the shops.

MINOR, in law, is an heir either male or female, before they arrive at the age of twenty-one; during the minority of such, they are usually incapable of acting for themselves.

MINOR, in logic, the second proposition of a regular syllogism.

MINOR, in music, signifies less, and is applied to certain concords or intervals which differ from others of the same denomination by half a tone: thus we say a third minor, meaning a less third; a sixth major and minor.

MINOTAUR, *minotaurus*, in antiquity, a fabulous monster much talked of by the poets, feigned to be half man and half bull.

MINSTREL, an antient term for a fiddler, or player on any other kind of musical instrument.

MINT, the place in which the king's money is coined. See COINAGE.

MINT, *Mentha*, in botany, a genus of plants, whose flower is monopetalous, and divided into four almost equal segments at the limb; it has no pericarpium, but the seeds, which are four in number, are contained in the bottom of the cup.

There are various species of mint, as spear-mint, pepper-mint, calimint, orange-mint, curled or crisp mint, water-mint, with several others of less note; but the most useful are the spear-mint and pepper-mint, which are so well known, that a description of them is unnecessary; these species are cultivated in our gardens for culinary and medicinal purposes; they are easily propagated by parting their roots in the spring, or by planting cuttings of them in the summer months.

Spear-mint is stomachic, cephalic, and carminative, it is excellent in the loss of appetite, reachings to vomit, as also in stopping fluxes of the belly; as it resolves coagulated blood, and eases the pains of the cholic; and its fragrant scent makes it enter into many compositions as a cephalic: it may be drank as tea, either green or dry, and the infusion should be strong.

Externally it is used with good success in fomentations outwardly applied, with hot cloths, to the stomach and belly in the forementioned cases.

Pepper-mint is more pungent to the taste than spear-mint: the distilled water from this plant is much in esteem for its great use in flatulent cholics, and many cold diseases; its effects are almost immediately felt, for it causes a glowing warmth to be felt throughout all parts of the body.

As the distilled water of all sorts of mint is esteemed a very wholesome cordial dram, it might be substituted instead of those intoxicating spirits which the common people make use of; for the pepper-mint water is as warm to the stomach as any other sort of dram, and more so than those noxious spirits; and if this was judiciously mixed with some other agreeable aromatic herbs, there might certainly be distilled a liquor much more palatable and wholesome than what is now vended in common, whereby the lower class of people would be less debauched; therefore it will be better for the public not only if the less hurtful drams were made, but also by the introducing more generally the distillation of herbs, there will be less occasion for the using of wheat for such purposes; which is a matter of no small consequence to this nation.

When mint is to be cut for medicinal use, it should be done in dry weather, just when it is in full flower; for if it is cut wet, it will change black and be good for nothing: it should be dried in the shade, and afterwards hung up in a dry place, where it may remain till it is wanted.

Cat MINT, *Nepeta*, in botany. See the article NEPETA.

MINUET, in music, a very graceful kind of dance, which consists of a couplee, a high step, and a balance; it begins with a beat, and its motion is triple.

MINUSCULE, the small letters, in contradistinction to the majuscule or capitals.

MINUTE, in geometry, the sixtieth part of a degree of a circle.

MINUTE of time, the sixtieth part of an hour.

MINUTE, in architecture, usually denotes the sixtieth, sometimes the thirtieth part of a module.

MINUTE is also used for a short memoir, or sketch of a thing taken in writing.

MIRABILIS, marvel of Peru, in botany, a genus of plants whose flower is monopetalous and infundibuliform, having a long slender tube sitting on a globose nectarium, with five filiform stamina. The fruit is an oval pentagonal nut, containing a single seed.

Tournefort and Linnæus will have the root of a species of this genus to be the true jalap of the shops, but Houston declares that the jalap is a root of a species of convulvulus; however, the roots of the known species of mirabilis are cathartic, and answer

# M I R

swer the same purpose as jalap if the dose is given in a double quantity.

MIRACLE, is defined by Dr. Samuel Clarke, to be a work effected in a manner different from the common and regular method of providence, by the interposition either of God himself or some intelligent agent superior to man.

MIRROUR, *Speculum*, in catoptrics, any polished body, impervious to the rays of light, and which reflects them equally.

Mirrors were anciently made of metal; but, at present, are generally smooth plates of glass, tinned or quicksilvered on the back part, and called looking-glasses.

The doctrine of mirrors depends wholly on that fundamental law, that the angle of reflection is always equal to the angle of incidence.

Let EH (plate LXXI. *fig.* 7.) be a concave mirror, V its vertex, and C the center of its concavity. Let A be a ray of the sun's light incident on the point E, and draw EC, which will be perpendicular to the mirror in the point E; make the angle CEF equal to the angle AEC, then shall EF be the reflected ray. Thus also HF will be the reflected ray of the incident one DH, at an equal distance on the other side of the axis BV.

If now the points E and H be taken very near the vertex V, we shall have EF, or HF, very nearly equal to FV; but  $EF = FC$ ; therefore  $FV = FC = \frac{1}{2} CV$ . That is, the focal distance FV of parallel rays will be at the distance of half the radius CV of the concavity of the mirror, from vertex V, in the axis BV.

After the same manner a convex mirror is shewn to reflect the rays AE, DH, (*fig.* 8.) into EF, HF, as if they came diverging from a point *f* in the axis CV, which is half the radius CV distant from the vertex V. But since the rays do not actually come at, or from the focus *f*, it is called the imaginary or virtual focus. See FOCUS.

Parallel rays falling directly on a plane speculum are reflected back upon themselves; if they fall obliquely, they are reflected in the same angle, and parallel as they fell. Hence there is no such thing, properly speaking, as a focus belonging to a plane speculum, neither real nor virtual.

The focus F, or *f*, of parallel rays, is called the solar focus; because in that the image of the sun is formed, and of all objects very remote. But the focus of any object situated near the mirror will have its distance from the vertex more or less than half the radius; the rule in all cases being as follows:

Multiply the distance of the object into the radius of the mirror, and divide the product by the sum of the radius and twice the distance of the object; the quotient will be the focal distance of a convex mirror.

Again for a concave mirror, the same product of the radius into the distance of the object, divided by the difference of radius and twice the distance of

# M I S

the object, will give the focal distance VF or V*f*. And here we are to observe, that, as twice the distance of the object, is lesser or greater than the radius, so the focus will be positive or negative, that is, behind the glass or before it.

The image of the object is formed in the focus proper to its distance: and, since the writers on optics demonstrate that the angles under which the object OB (*fig.* 9.) and its image IW are seen from the center or vertex of the mirror C are always equal, it follows, that the image IW will be always in proportion to the object OB, as the focal distance VF to the object's distance GV. The position of the object will be always erect at a positive focus, or behind the speculum; diminished by a convex, and magnified by a concave one. Hence, since a convex has but one, *viz.* an affirmative focus, so it can never magnify any object, howsoever posited before it.

The position of the image in a negative focus, or that before the glass, will be ever inverted; and, if nearer the vertex than the center C, it will be less; if farther from it, it will be greater than the object; but in the center it will be equal to the object, and seem to touch it.

The image formed by a plane speculum is erect; large as the life; at the same apparent distance behind the glass as the object is before it; and on the same side of the glass with the object. Those properties render this sort of mirror of most common use, *viz.* as a looking-glass.

If the rays fall directly, or nearly so, on a plane mirror and the object be opaque, there will be but one single image formed, or at least be visible; and that by the second surface of the speculum, and not by the first, through which the rays do most of them pass.

But if the object be luminous, and the rays fall very obliquely on the speculum, there will be more than one image formed, to an eye placed in a proper position to view them. The first image being formed by the first surface will not be so bright as the second, which is formed by the second surface. The third, fourth, &c. images, are produced by several reflexions of the rays between the two surfaces of the speculum; and, since some light is lost by each reflection, the images from the second will appear still more faint and obscure, to the eighth, ninth, or tenth, which can scarcely be discerned at all.

MISCHNAH, or MISNAH, the code or collection of the civil law of the Jews.

MISDEMEANOR, in law, signifies a heinous offence or fault, particularly in the execution of an office.

MISEN, or MIZEN, in a ship. See the article MIZEN.

MISERERE MEI, in medicine, the name by which some call the illiac passion.

MISLETOE,

# MIT

**MISLETOE**, *Viscum*, in botany, a plant, which instead of rooting and growing in the earth like other plants, fixes itself and takes root on the branches of trees, spreading out in dichotomous branches so as to form a large bush; the flowers come out from the wings of the stalk, and are male on some plants and female on others; they are both apetalous: the male flower consists of a cup, formed of four oblong leaves, each having an oblong acuminate antheræ affixed to it: the female flower has a deciduous cup, formed of four small oval leaves, sitting on an oblong three-cornered germen, which becomes a smooth, round, unilocular berry, containing a fleshy, compressed, heart-shaped seed.

Mistletoe grows more readily on the apple and ash, and other smooth rind trees, than on others. It is supposed that the mistletoe-thrush, which feeds on the berries of this plant in winter (at which time they are ripe) often carries the seeds from tree to tree, for the viscous part of the berry which surrounds the seed, sometimes sticks fast to the outer part of the bill of the bird, which to disengage himself from, strikes it against the branches of a neighbouring tree, and by that means, leaves the seed sticking on the bark, which will grow in the following winter; and it may be propagated by art in the same manner. Mistletoe is sometimes found on the oak, though but rarely, which, perhaps, is the reason why that is valued more than others.

Mistletoe is esteemed as a great anti-epileptic, and good in other nervous disorders; the dose of it in powder is from one dram to two. The berries purge upwards and downwards with great violence, and therefore are not proper to be given inwardly.

**MISNOMER**, in law, a misnaming, or mistaking a person's name.

**MISPRISION**, signifies, in general, some neglect or oversight; as where a person is privy to a treason or felony committed by another, and neglects to reveal it to the king or his council, or to a magistrate, but entirely conceals it: this is called misprision of those crimes.

**MISSIONARIES**, such ecclesiastics as are sent by any Christian church, into pagan or infidel countries, to convert the natives, and establish the Christian religion among them.

**MISUSER**, in law, signifies some abuse of any particular liberty or benefit. The charter of a corporation, as well as an office, may be forfeited by misuser.

**MITCHELLA**, in botany, a genus of the tetrandria monogynia class of plants, the calyx of which consists of two flowers, placed upon the germen; the corolla is monopetalous and funnel-shaped: the fruit is a bipartite globose berry: the seeds are compressed and callous.

**MITE**, a small coin, formerly current, equal to about one-third part of a farthing.

It also denotes a small weight, used by the mo-

# MIZ

neyers: it is equal to the twentieth part of a grain, and is divided into twenty-four doits.

**MITE**, in zoology. See **ACARUS**.

**MITELLA**, in botany, a genus of the decandria digynia class of plants, the corolla whereof consists of five patent petals, of an oblong figure, longer than the segments of the cup, with their unguis narrow, and inserted into the calyx: the fruit is a capsule of a globose figure, but with a point formed of two valves, and opening between, containing only one cell: the seeds are numerous, and of a roundish oblong figure.

**MITHRADATE**, in pharmacy, a compound medicine in form of an electuary, serving either as a remedy or preservative against poisons; being also accounted a cordial, opiate, sudorific, and alexipharmic.

**MITRALES VALVULÆ**, mitral valves, in anatomy, two valves situated in the left ventricle of the heart, at the ingress of the pulmonary vein, serving to hinder the ingress and regress of the blood from the heart into the veins again, while they are constricted.

**MITRE**, a sacerdotal ornament, worn on the head by bishops and certain abbots on solemn occasions; being a sort of cap, pointed and cleft at top.

**MITTIMUS**, as generally used, hath two significations. 1. It signifies a writ for removing and transferring of records from one court to another. 2. It signifies a precept, or command in writing, under the hand and seal of a justice of the peace, directed to the gaoler or keeper of some prison, for the receiving and safe-keeping of an offender charged with any crime until he be delivered by due course of law.

**MIXT**, or **MIXED BODY**, in philosophy and chemistry, that which is compounded of different elements or principles; in which sense, it stands contradistinguished from simple or elementary, which is applied to bodies consisting of one principle only, as the chemists take sulphur, salt, &c. to do. The business of chemistry is, to resolve mixt bodies into their principles or component parts.

**MIXT ACTION**, in law, is an action, partly real and partly personal, which lies both for the thing detained, and against the person of the detainer. See **ACTION**.

**MIXTURE**, a compound, or assemblage of several different bodies in the same mass.

**MIXTURA SIMPLEX**, a medicinal preparation made in the following manner: Take of the spiritus theriacalis camphoratus of Bates, ten ounces; spirit of vitriol, two ounces; rectified spirit of tartar, six ounces. Digest in a glass vessel, hermetically sealed, for three weeks. This medicine excites sweat, resists putrefaction, and is good in malignant fevers. The dose is about a dram.

**MIZEN**, in the sea-language, is a particular mast or

or sail. The mizen-mast stands in the sternmost part of the ship. In some great ships there are two of these; when that next the main-mast is called the main-mizen, and that next the poop, the bonaventure-mizen. The length of the mizen-mast is, by some, accounted the same with the height of the main-top-mast from the quarter-deck; or half the length of the main-mast, and half as thick. The sail which belongs to the mizen-mast, is called the mizen-sail: and when the word mizen is used at sea, it always means the sail. The use of the mizen is to keep the ship close to the wind, or when a ship rides at anchor, to back her astern, so that she may not foul her anchor, on the turning of the tide.

**MNEMONIC**, something relating to the memory. See **MEMORY**.

**MNIUM**, in botany, a genus of mosses, consisting of stalks furnished with leaves, and producing capsules raised on pedicles, like those of the other mosses of this class; but besides these, there are other pedicles, bearing a kind of naked heads, with a dusky surface, and having no calyptræ. These two kinds of heads are, in some species, produced on the same plant; and in others, on different plants of the same species. The pedicles that support the capsules are long and naked; whereas those supporting the dusky heads are short, and in some species furnished with short leaves.

**MOAR-LOVRE**, in husbandry, a sort of blight, which happens mostly on light land, from the earth's sinking away from the roots, so that the plants fall down to the earth.

To remedy this, they turn a shallow furrow against the rows, when they are strong enough to bear it, and when the mould is fine and dry; for then, the motion of the stalks by the wind, will cause such earth to run through the rows, and settle about the roots, and cover them.

**MOARING**, or **MOORING**, in the sea-language. See the article **MOORING**.

**MOAT**, or **DITCH**, in fortification, a deep trench dug round the rampart of a fortified place, to prevent surprizes.

The brink of the moat, next the rampart, is called the scarpe; and the opposite one, the counter-scarpe.

**MOBILE**, or **PRIMUM MOMILE**, the ninth sphere in the Ptolemaic System of Astronomy. See the article **PTOLEMAIC**.

**MODE**, *Modus*, in philosophy, denotes the manner of a thing's existence, which is twofold; viz. simple or mixed.

Simple modes are only combinations of the same simple idea: thus, by adding units together, in distinct separate collections, we come by all the several modes of numbers, as a dozen, a score, a thousand, &c.

Mixed modes, on the contrary, are compounded of simple ideas of different kinds, as beauty, which consists in a certain composition of colour and figure, causing delight in the beholder: such also is theft, which is the concealed change of the possession of a thing, without the consent of the proprietor.

**MODE**, in music, is defined to be a particular manner of constituting the octave; or, it is the melodious constitution of the octave, as it consists of seven essential sounds, besides the key or fundamental. See the article **OCTAVE**.

**MODEL**, in a general sense, an original pattern, proposed for any one to copy or imitate.

This word is particularly used, in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is much the surest way to make a model in relievo, and not to trust to bare design or draught. There are also models for the building of ships, and for extraordinary stair-cases, &c.

They also use models in painting and sculpture; whence, in the academies, they give the term model to a naked man or woman, disposed in several postures to give an opportunity to the scholars to design him in various views and attitudes.

**MODERATOR**, in the schools, the person who presides at a dispute, or in a public assembly: thus, the president of the annual assembly of the church of Scotland, is stiled moderator.

**MODERN**, in a general sense, something new, or of our time, in opposition to what is antique or ancient.

**MODIFICATION**, in philosophy, that which modifies a thing, or gives it this or that manner of being.

**MODILLIONS**, in architecture, ornaments in the cornice of the Ionic, Corinthian, and Composite columns.

The modillions are little inverted consoles, or brackets, in form of an S, under the soffit of the cornice, seeming to support the projecture of the larmier; though in reality they are no more than ornaments.

They ought always to be placed over the middle of the column. They are particularly affected in the Corinthian order, where they are usually enriched with sculpture. Their proportions ought to be so adjusted, as to produce a regularity in the parts of the soffits. The intermodillions (i.e. the distances between them) depend on the inner columns, which oblige the modillions to be made of a certain length and breadth, in order to render the intervals perfect squares, which are always found to have better effects than parallelograms. To this it must be added, that in adjusting the modillions, care should

## MOH

should be taken that they have such a proportion as that when the orders are placed over one another, there be the same number in the upper order as in the lower, and that they fall perpendicular over one another.

**MODIOLUS**, in surgery, an instrument otherwise called a trepan. See **TREPAN**.

**MODIUS**, in antiquity, a kind of dry measure, in use among the Romans, for several sorts of grain. See **MEASURE**.

**MODO ET FORMA**, in manner and form, among lawyers, are words of art, frequently used in pleadings, &c. and particularly in a defendant's answer, wherein he denies to have done what is laid to his charge in manner and form, as affirmed by the plaintiff.

**MODULATION**, in music, the art of keeping in, or changing the mode or key. See the articles **KEY** and **MODE**.

Under this term is comprehended, the regular progression of several parts, through the sounds that are in the harmony of any particular key, as well as the proceeding naturally and regularly from one key to another; the rules of modulation, in the first sense, belonging to harmony and melody. See the articles **HARMONY** and **MELODY**.

**MODULE**, in architecture, a certain measure or bigness, taken at pleasure, for regulating the proportions of columns, and the symmetry or disposition of the whole building.

Architects generally choose the semi-diameter of the bottom of the column for their module, and this they sub-divide into parts or minutes. The module of Vignola, which is a semi-diameter, is divided into twelve parts in the Tuscan and Doric, and into eighteen for the other orders.

The module of Palladio, Scamozzi, M. Cambray, Desgodetz, Le Clerc, &c. (which is also equal to the semi-diameter) is divided into thirty parts or minutes in all the orders.

The whole height of the column is divided, by some, into twenty parts for the Doric, twenty-two and a half for the Ionic, twenty-five for the Roman, &c. and one of these parts is made a module, to regulate the rest of the building.

**MODUS DECIMANDI**, in law, is where money, land, or other valuable consideration, has been given, time out of mind, to the minister or parson of any certain place in the room of tithes.

A clergyman may sue in a spiritual court for a *modus decimandi*; yet if the *modus* is denied there, or a custom is to be tried, the trial thereof belongs to the courts of common law. When lands are converted to other uses, as in the case of hay-ground turned into tillage, the *modus* may be discharged, and the tithes paid again in kind.

**MOEDORE**, or **MOIDORE**. See the article **MOIDORE**.

**MOHERINGIA**, mossy-chickweed, in botany,

## MOL

a genus of the octandria-digynia class of plants, the flower of which is composed of four short undivided petals; and its fruit is a subglobose capsule, with one cell, in which are contained numerous roundish seeds.

It is called by some, *alfine muscosa*.

**MOGULS**, or **MONGULS**, hoards or tribes of vagrant Tartars, on the north of India, from whom the moguls or sovereigns of India, as well as of the Ubec-Tartars, are descended.

**MOHAIR**, in commerce, the hair of a kind of goat, frequent about Angoura, in Turkey; the inhabitants of which city are all employed in the manufactures of camblets, made of this hair.

**MOHAIR-SHELL**, in natural history, a species of voluta. See **VOLUTA**.

**MOIDORE**, or **MOEDORE**, a Portuguese gold coin. See **EXCHANGE**.

**MOIETY**, *medietas*, the half of any thing. See **MEDIETAS**.

**MOINEAU**, in fortification, is a flat bastion raised between two other bastions, when a re-entering angle before a curtain is too long.

The moineau is commonly joined to the curtain, but it is sometimes separated from it by a foss, in which case it is called a detached bastion. The moineau is not raised so high as the works of the place, because it ought to be exposed to the fire of the place, in case the enemy should lodge themselves in it.

**MOISTURE**, a term sometimes used to denote animal fluids, the juices of plants, or dampness of the air, or other bodies.

*Radical Moisture*, among physicians, signifies a vital fluid, which nourishes and maintains life, as oil does a lamp. However, Dr. Quincy observes, that such a fluid is a mere chimera, unless we thereby mean the mass of blood. See **BLOOD**.

**MOLA**, in anatomy, the same with patella. See **PATELLA**.

**MOLA**, the sun-fish, in ichthyology, a species of ostracion, of a compressed roundish figure, with four holes on the head.

This is a very singular fish, weighing often more than an hundred pounds: its figure, at first sight, more resembles the head of some large fish, cut off from the body, than that of a complete animal.

**MOLA**, a mole, in medicine. See the article **MOLE**.

**MOLARES**, or **DENTES MOLARES**, in anatomy, the large teeth, called in English, grinders. See the article **TOOTH**.

**MOLE**, *talpa*, in zoology, makes a genus of quadrupeds, of the order of the feræ, thus characterized: the feet are formed like hands, and calculated for digging; and it has no external ears.

**MOLE-CRICKET**, the same with *gryllo talpa*. See **GRYLLO TALPA**.

**MOLE**, *mola Carnea*, in medicine, a mass of fleshy

fleshy matter, of a spherical figure, generated in the uterus, or womb, and sometimes mistaken for a child. Its size is various, from that of a large nut to that of a foetus. Some moles are soft and spongy, and others membranous, with a cavity in the middle. Sometimes they are filled with serous matter, and sometimes with hydatides.

**MOLE**, *Moles*, is a massive work of large stones laid in the sea by means of cofferdams, extending before a port, either to defend the harbour from the impetuosity of the waves, or to prevent the passage of ships without leave.

**MOLINE**, or **CROSS-MOULIN**, in heraldry, the same with that called *Fer de moulin*. See **FER DE MOULIN**.

**MOLLUGO**, bastard-madder, in botany, a plant of the triandria-trigynia class, without any flower petals. Its fruit is a capsule of a somewhat oval figure, with three cells, in each of which there is a number of kidney-shaped seeds.

It is said to have the same medicinal virtues as madder.

**MOLOSSES**, in commerce, the thick fluid matter remaining after the sugar is made, resembling syrup. See **SUGAR**.

**MOLOSSUS**, in Greek and Latin poetry, a foot composed of three long syllables, as *delectant*.

**MOLTA**, or **MOLTURA**, a toll or duty formerly paid by vassals to their lord, for grinding their corn in his mill.

**MOLTING**, the change of feathers, hairs, or horns, in birds and beasts.

**MOLUCCA-BEANS**, *Moluccella*, in botany, a genus of plants, the flower of which is monopetalous and labiated; the upper-lip being entire, and the lower one trifid: the seeds are turbinated, and contained in the bottom of the cup.

**MOMENT**, in the doctrine of time, an instant, or the most minute and indivisible part of duration. See **TIME**.

Strictly speaking, however, a moment ought not to be considered as any part of time, but only as the termination or limit thereof.

**MOMENT**, in the doctrine of infinites, denotes the same with infinitesimal. See the article **INFINITESIMAL**.

**MOMENTUM**, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter, multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity. See **MOTION**.

**MONADELPHIA**, in botany, a class of plants, the sixteenth in order, so called because the stamina of the flowers are so interwoven as to form one body; or rather, because the stamina are connected, or coalesce at the base.

**MONANDRIA**, in botany, a class of plants, the first in order, with only one stamen, or male part in each flower.

The monandria are subdivided into two orders, which are denominated monandria-monogynia, and monandria-digynia, according as they contain one or two styles.

**MONARDIA**, in botany, a genus of plants, with a monopetalous flower, the rim of which is ringent: the seeds are four in number, roundish, and contained in the bottom of the cup.

**MONASTERY**, a convent, or house built for the reception and entertainment of monks, mendicant friars, or nuns, whether it be an abbey, priory, &c.

**MONASTIC**, something belonging to monks. See **MONKS**.

**MONDAY**, *Dies Lunæ*, the second day of the week, so called as being anciently sacred to the moon, q. d. moon-day.

**MONEY**, *Moneta*, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight to serve as a medium in commerce.

Money is usually divided into real and imaginary. Real money includes all coins, whether gold, silver, copper, or the like; such as guineas, crowns, pistoles, pieces of eight, ducats, &c.

Imaginary money, or money of account, is that which has never existed, or, at least, which does not exist in real species; but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed like current coins, which the authority of the sovereigns sometimes raises or lowers, according to the exigencies of the state, of which kinds are pounds, livres, marks, maravedes, &c.

**MONEYERS**, **MONEYORS**, or **MONIERS**, officers of the mint, who work and coin gold and silver money, and answer all waste and charges.

**MONITORY LETTERS**, are letters of warning and admonition, sent from an ecclesiastical judge, upon information of scandals and abuses, within the cognizance of his court.

**MONK**, a person who wholly dedicates himself to the service of religion, in some monastery, under the direction of some particular statutes and rules.

The most probable account of the origin of the monks is, that in the decian persecution, in the middle of the third century, many persons in Egypt, to avoid the fury of the storm, fled to the neighbouring deserts and mountains, where they not only found a safe retreat, but also more time and liberty to exercise themselves in acts of piety and divine contemplations; which sort of life became so agreeable, that when the persecution was over, they refused to return to their habitations again, choosing rather to continue in those cottages and cells, which

they had made for themselves in the wilderness. From that time to the reign of Constantine, monachism was confined to the hermits or anachorets, who lived in private cells in the wilderness: but when Pachomius had erected monasteries, other countries presently followed the example.

The manner of admission to the monastic life was usually by some change of habit, not to signify any religious mystery, but only to express their gravity and contempt of the world. Long hair was always thought an indecency in men, and favouring of secular vanity, and therefore they polled every monk at his admission, to distinguish him from seculars; but they never shaved them, lest they should look like the priests of Isis. St. Jerome, speaking of the habits of the monks, intimates that it differed from that of others only in this, that it was cheaper, coarser, and meaner raiment. We read of no solemn vow, or profession, required at their admission; but they underwent a triennial probation, during which time they were inured to the exercises of the monastic life. If, after that time was expired, they chose to continue the same exercises, they were then admitted, without any farther ceremony, into the community. As the monasteries had no standing revenues, all the monks were obliged to maintain themselves by their daily labour: they had no idle mendicants among them, but looked upon a monk who did not work, as a covetous defrauder. Every ten monks were subject to one, who was called decanus, or dean, from his presiding over ten; and every hundred had another officer called centenarius, from his presiding over an hundred; and above these were the fathers of the monasteries, also called abbots. The business of the deans was to exact every man's daily task, and carry it to the steward, who gave a monthly account of it to the abbot.

MONK-SEAM, among sailors, is the sewing the edges or selvages of sails together, over one another on both sides, to make it the stronger.

MONKEY, *Simia*, in zoology, a numerous genus of quadrupeds of the order of the anthropomorphia, or quadrupeds that resemble the human figure: their face is naked; the claws are roundish and flattish, in some degree like the nails on the human hand; and they have both an upper and lower eyelid.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds.

It is formed of a rule, divided and subdivided into several parts, on which there is a moveable string stretched upon two bridges, at each extreme. In the middle between these is a moveable bridge, by means of which, in applying it to the different divisions of the line, the sounds are found to bear the same proportion to each other, as the divisions of the line, cut by the bridge. There are also monochords with forty-eight fixed bridges.

The monochord is also called the harmonical canon, or the canonical rule, because it serves to measure the degrees of gravity or acuteness.

\* Monochord is also used for any musical instrument, that consists of only one string or chord; in this sense the trumpet-marine may properly be called a monochord.

MONOCULUS, in zoology, a genus of crustaceous water-insects of the aptera-order, the body of which is short, roundish, and covered with a firm crustaceous skin; its fore legs are ramose, and serve for leaping and swimming: and it has only one eye, composed of three smaller ones.

MONODON, in ichthyology, a fish of the whale-kind, otherwise called narwal, or the sea-unicorn.

MONODY, in ancient poetry, a mournful kind of song, sung by a person all alone, to give vent to his grief.

MONOECIA, in botany, one of Linnæus's classes of plants, the twenty-first in order; in which the male and female flowers are placed separately on the same plant, or rather on different stalks growing from the same root.

Of the plants belonging to this class, some have only one stamen, and others have three, four, five, six, or more stamina; whence the subordinate orders of monoecia-monandria, monoecia-triandria, &c. others again are monadelphous, others syngenesious, and others gynandrous.

MONOGRAM, a character or cypher, composed of one, two, or more letters, interwoven; being a kind of abbreviation of a name, antiently used as a seal, badge, arms, &c.

MONOLOGUE, in poetry, a dramatic scene, in which a person appears alone on the stage, and speaks to himself.

MONOMIAL, in algebra, a root or quantity that has but one name, or consists of only one member, as *ab*, *aab*, &c.

MONOPETALOUS, in botany, a term applied to flowers that have only one petal, or flower-leaf.

MONOPOLY, one or more persons making themselves the sole masters of the whole of a commodity, manufacture, and the like, in order to make private advantage of it, by selling it again at a very advanced price.

MONOPTERE, in architecture, a kind of temple, round, and without walls, having a dome supported by columns.

MONOPTOTON, in grammar, a noun that has only one case, as *inficias*.

MONOPYRENEOUS, in botany, such fruit as contains only one seed, or kernel.

MONORHYME, a piece of poetry, in which all the verses end with the same rhyme.

MONOSTICH, an epigram that consists of only one single verse.

**MONOSYLLABLE**, in grammar, a word that consists of only one syllable, and is composed of either one or more letters pronounced at the same time.

**MONOTHELITES**, a sect of Christians in the seventh century, so called from their maintaining, that though there were two natures in Jesus Christ, the human and divine, there was but one will, which was the divine.

**MONOTONY**, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tone.

**MONOTROPA**, in botany, a genus of plants, the flower of which consists of ten oblong deciduous petals, serrated at the tops: the fruit is an oval, pentagonal, obtuse capsule, containing a great number of paleaceous seeds.

This genus comprehends the orobanchoides of Tournefort, and the hypopitys of Dillenius.

**MONSOON**, in physiology, a species of trade-wind, in the East-Indies, which for six months blows constantly the same way, and contrary the other six. See **WIND**.

**MONTH**, *Menfis*, in chronology, the twelfth part of a year.

Time being duration, marked out for certain uses, and measured by the motion of the heavenly bodies, there thence results divers kinds of months as well as years different from one another according to the particular luminary by whose revolution they are determined, and the particular purposes they are destined for: hence months are of two kinds, astronomical and civil.

An astronomical month is that which is governed either by the motion of the sun or moon, and is consequently of two kinds, solar and lunar: a solar month is that time, in which the sun seems to run through a whole sign, or, the twelfth part of the ecliptic.

Hence, if regard be had to the sun's true apparent motion, the solar month will be unequal, since the sun is longer in passing through the winter-signs than through those of the summer; but as he constantly travels through all the twelve signs in 365 days, 5 hours and 49 minutes the quantity of a mean month will be had, by dividing that number by 12; on this principle, the quantity of a solar month will be found to be 30 days, 10 hours, 29 minutes, 5 seconds. See **EARTH**.

A lunar month is that space of time which the moon takes up in performing its course through the zodiac, or, that measured by the motion of the moon round the earth; and is of three kinds, *viz.* periodical, synodical, and that of illumination. The lunar periodical month, is the space of time wherein the moon makes her round through the zodiac, or wherein she returns to the same point, being 27 days, 7 hours, 43 minutes, 5 seconds. See the article **MOON**.

The lunar synodical month, called also absolutely the lunar month and lunation, is the space of time between two conjunctions of the moon with the sun; or the time it takes from one conjunction with the sun to the next; or from one new moon to another: the quantity of a synodical month is 29 days, 12 hours, 44 minutes, 3 seconds, and 11 thirds. The quantity of a synodical month is not the same at all times, for in the summer solstice, when the sun seems to move slowest, the synodical month appeareth less, being about 29 days, 6 hours, 42 minutes; but in the winter, when the sun's motion seems faster, the moon does not fetch up the sun so soon, for which reason the synodical month then seems greater, *viz.* 29 days, 19 hours, and 37 minutes, according to the observation of the same astronomers: so that the first quantity given of the synodical month, is to be understood as to the mean motion. From what has been said, it may easily appear that the difference between a periodical and synodical month is this: the first is called periodical in respect of the moon's orbit; but the synodical is so called in respect of its connection with the other luminary.

Now after the time of its conjunction, the sun does not continue in the same place of the zodiac, but moves forwards to the east, upon which it falls out that the moon, finishing its course does not find the sun again in the same place where it left him, he being removed almost a whole sign from his former place, so that to overtake the sun again, it plainly appears that a certain space of time is requisite besides the periodical, which makes up the synodical month.

The ancient Romans made use of the lunar months, and made them alternately of 29 and 30 days; and they marked the days of each month by three terms, *viz.* calends, nones, and ides. See the articles **CALENDS**, &c.

The lunar month of illumination, or apposition, or illuminative month, is the space from the first time of the moon's appearance after new moon, to her first appearance after the new moon following. The lunar month of illumination, is not of any determined quantity, because the moon appears sometimes sooner, and sometimes later, after the conjunction; for which diversity astronomers give us several reasons, particularly the obliquity of the zodiac, the variable latitude of the moon, the apparent inequality of its motion, the different qualities of the summer and winter-air, &c. By this month, however, the Turks and Arabs go; and it is said that the antient Britons went by the phases of the moon.

A civil or political month, consists of a certain number of days, according to the laws and customs of the different countries wherein it is used, either having no regard to the solar or lunar months, as those of the Egyptians in their equal year, of the

Romans in the year of Romulus, &c. or coming pretty near to the solar astronomical month, as the Julian; or else the lunar astronomical, as the Jewish, Turkish, and others. The British, and most European nations, make 12 months in the year, viz. January, February, &c.

Civil solar months, are such civil months as are accommodated to the astronomical months, or those which are to consist alternately of 30 and 31 days, excepting one month of the twelve, which, for every fourth year, consisted of 30 days, and for the other years of 29. This form of civil months was introduced by Julius Cæsar; but under Augustus, the sixth month, till then, from its place, called Sextilis, was denominated Augustus, in honour of that prince; and to make the compliment yet the greater, a day was added to it, so that now it consists of 31 days, though till then it had only 30; to make up for which, a day was taken from February, so that from thenceforward it only consisted of 28 days, and every fourth year of 29; though before it had ordinarily consisted of 29 days, &c. and such are the civil or calendar months which now obtain throughout Europe.

Civil lunar months are to consist alternately of 29 and 30 days: thus will two civil months be equal to two astronomical ones, abating for the odd minutes, and consequently the new moon will be hereby kept to the first day of each such civil month, for a long time together. However, to make them keep constantly pace with the civil months, at the end of each 948 months, a month of 29 days must be added; or else, every 33d month must consist of 30 days. This was the month in civil or common use among the Jews, Greeks, and Romans, till the time of Julius Cæsar.

*Philosophical MONTH*, among chemists, is the space of 40 days and nights.

*MONTIA*, blinks, in the Linnean system of botany, a genus of the triandria-tryginia class of plants, the corolla whereof consists of a single petal, and is divided at the extremity into five parts; three of the segments are smaller than the others, and produce stamina; these stand alternately with the two larger: the fruit is a turbinate obtuse capsule, covered by the cup, composed of three valves, and having three cells: the seeds are three in number, and roundish.

*MONUMENT*, in architecture, a building destined to preserve the memory, &c. of the person who raised it, or for whom it was raised; such are a triumphal arch, a mausoleum, a pyramid, &c.

*MOOD*, or *MODE*, called also syllogistic mood, a proper disposition of the several propositions of a syllogism, in respect of quantity and quality.

*MOOD*, or *MODE*, in grammar, the different manner of conjugating verbs, serving to denote the different affections of the mind.

Hence arise four moods, viz. the indicative, subjunctive, and imperative: of these, the three first are called finite moods, because they define a certain person and number; but the fourth is called the infinitive, because in it there is no distinction of either person or number.

*MOON*, *Luna*, *Δ*, in astronomy, a satellite, or secondary planet, always attendant on our earth.

Of the six primary planets, we find but three that are certainly attended with moons, viz. the earth, Jupiter, and Saturn; for though Mr. Short has given an account of a phenomenon that he observed some years ago, which seems extremely like a moon about Venus, yet, as it was never observed before nor since, through the best of telescopes, it does not appear to be a moon. See *JUPITER*, *EARTH*, and *SATURN*.

Astronomers have drawn the face of the moon, according as it is seen with the best telescopes; for which we are obliged to the accurate labours of the famous selenographers Florentius, Langrenus, John Hevelius of Dantzic, Grimaldus and Ricciolus, Italians; who have taken particular care to note all the shining parts of the moon's face, and, for the better distinguishing them, they have given to each part a proper name. Langrenus and Ricciolus have divided the lunar regions among the philosophers and astronomers, and other eminent men; but Hevelius, fearing lest the philosophers should quarrel about the divisions of the lands, has spoiled them of this their property, and given the parts of the moon those geographical names that belong to the different islands, countries, and seas, that belong to our earth, without any regard to their situation or figure.

That the surface of the moon is not smooth or even, but diversified with hills and vales, continents and seas, lakes, &c. any one would imagine, who views her face through a large telescope. That she has variety of hills and mountains is demonstrable from the line which bounds the light and dark parts not being an even and regular curve, as it would be upon a smooth spherical surface, but an irregular broken line, full of dents and notches.

Also because some small (and many large) bright spots appear in the dark portion, standing out at several distances from the boundary line; which spots in a few hours become larger, and at last unite with the enlightened portion of the disk.

On the other hand, we observe many small spots interspersed all over the bright part, some of which have their dark sides next the sun, and their opposite sides very bright and circular, which infallibly proves them to be deep, hollow, round cavities; of which there are two very remarkable ones near together on the upper part, and may be viewed exceedingly plain, when the moon is about four or five days old. The depth of these lunar cavities prodigiously exceeds the height of the mountains, and con-

consequently the surface of the moon has but little resemblance to that of the earth in these respects.

Since, then, the moon's surface appears to be so very mountainous and irregular, it has been a question, how it comes to pass that the bright circular limb of the disk does not appear jagged and irregular, as well as the curve bounding the light and dark parts: in answer to this, it must be considered that, if the surface of the moon had but one row of mountains placed round the limb of the disk, the said bright limb would then appear irregularly indented; but since the surface is all over mountainous, and since the visible limb is to be considered not as a single curve line, but a large zone, having many mountains one behind another, from the observer's eye, it is evident the mountains in some rows being opposite to the vales in others, will fill up the inequalities in the visible limb in the remoter parts, which diminish to the sight and blend with each other, so as to constitute, like the waves of the sea, one uniform and even horizon. Whether there be seas, lakes, &c. in the moon, has been a question long debated, but now concluded in the negative: for in those large, darker regions, which were thought to be seas, we view, through a good telescope, many permanent bright spots, as also caverns and empty pits, whose shadows fall within them, which can never be seen in seas or any liquid substance. Their dark and dusky colour may proceed from a kind of matter or soil, which reflects light less than that of the other regions. These spots have continued always the same unchangeably, since they were first viewed with a telescope; though less alterations than what happen in the earth, in every season of the year, by verdure, snow, inundations, and the like, would have caused a change in their appearance. But indeed as there are no seas nor rivers in the moon, and no atmosphere, so of course there can be no clouds, rain, snow, or other meteors, whence such changes might be expected.

Sir Isaac Newton mentions an atmosphere about the moon, but other astronomers think there is reason (not to say a demonstration) for the contrary: for where there an atmosphere of air like ours, it must necessarily obscure the fixed stars in the moon's appulse to them: but it has been observed that this never happens: on the contrary, they preserve all their splendor to the moment of their occultation, and then disappear instantaneously, and in the same manner they recover their light, when they appear again on the other side.

The distance of our moon from the earth is determined by her horizontal parallax, or the angle which the semidiameter of the earth subtends at the moon, viz. the angle AOC (Plate LXXII. fig. 1.) which is the difference between the true place of the moon's center O, when in the horizon, and the apparent place thereof, as viewed from the surface

of the earth at A. The former is known by astronomical tables, the latter by observation: and the quantity of this difference, or angle, at a mean, is  $57' 12'' = AOC$ .

If therefore we say, as the tangent of  $57' 12''$  is to radius, so is  $AC = r$  to  $CO = 60,1$ ; this will be the mean distance of the moon in semidiameters of the earth. Therefore, since one semidiameter of the earth contains 3982 miles, we have  $3982 \times 60,1 = 239318,2 = CO$ , the mean distance of the moon.

The moon's apparent semidiameter MO measures, at her mean distance,  $15' 38'' = 938''$  by the micrometer, which is the quantity of the angle MCO. The earth's diameter, therefore, is to the moon's, as  $3432''$  to  $938''$ ; that is, as 109 to 30, or, as  $3,63$  to 1. Wherefore  $\frac{30}{109} \times 7964 = 2192$  miles the moon's diameter.

Therefore the face of the earth, as it appears to the lunarians, is to the face of the moon, as it appears to us, as  $109 \times 109$  to  $30 \times 30$ , viz. as 11881 to 900, or as 12,2 to 1. And the real bulk of the earth is to that of the moon as  $109 \times 109 \times 109$  to  $30 \times 30 \times 30$ , viz. as 1295029 to 27000, that is, as 1295 to 27, or as 48 to 1 very nearly.

Since, as we have shewn, the mean distance of the moon is about 60 semidiameters of the earth, at the distance of the moon one degree of the earth's surface will subtend an angle of one minute, and will therefore be visible; but such a degree is equal to  $69\frac{1}{2}$  miles; therefore a spot or place 70 miles in diameter, in the moon, will be just visible to the naked eye. Hence a telescope that magnifies about 100 times, will just discover a spot whose diameter is  $\frac{1}{100}$  of 70 miles, or  $\frac{7}{10}$  of a mile of 3698 feet: and a telescope that will magnify 1000 times, will shew an object that is but  $\frac{1}{1000}$  of a mile; that is, whose diameter is but 370 feet, or little more than 120 yards; and therefore will easily shew a small town or village, or even a gentleman's seat, if any such there be.

The time which the moon takes up in making one revolution about the earth, from a fixed star to the same again, is 27d. 7 h. 43', which is called the periodical month. But the time that passes between two conjunctions, that is, from one new moon to another, is equal to 29d. 12 h. 44' 3'', which is called a synodical month: for, after one revolution is finished, the moon has a small arch to describe to get between the sun and the earth, because the sun keeps advancing forward in the ecliptic. Now this surplus of motion takes up 2 d. 5 h. 1' 3'', which added to the periodical month, makes the synodical, according to the mean motions.

The moon moves about its own axis in the same time that it moves about the earth, from whence it comes to pass that she always shews the same face to us: for by this motion about her axis, just so

much of her surface is turned towards us constantly, as by her motion about the earth would be turned from us.

But since this motion about the axis is equable and uniform, and that about the earth, or common center of gravity, is unequal and irregular, as being performed in an ellipsis, it must follow that the same part of the moon's surface, precisely, can never be shewn constantly to the earth; and this is confirmed by the telescope, through which we often observe a little gore or segment on the eastern and western limb appear and disappear by turns, as if her body librated to and fro; which therefore occasioned this phenomenon to be called the moon's libration. The orbit of the moon is elliptical, more so than any of the planets, and is perpetually changing and variable, both in respect of its figure and situation; of which we shall treat more largely further on. The inclination of the moon's orbit to the plane of the ecliptic is also variable, from  $5^{\circ}$  to  $5^{\circ} 18'$ . The line of the nodes likewise has a variable motion from east to west, contrary to the order of the signs, and completes an entire revolution in a space of time a little less than nineteen years. Also the line of the apses, or of the apogee and perigee, has a direct motion from west to east, and finishes a revolution in the space of about nineteen years. All which will be more copiously treated of, when we come to explain the physical causes thereof.

The phases of the moon in every part of the orbit, are easily accounted for from her different situation with respect to the earth and sun: for, tho' to an eye placed in the sun she will always exhibit a complete illuminated hemisphere, yet in respect to the earth, where the hemisphere is viewed in all degrees of obliquity, it will appear in every degree from the greatest to the least; so that at E (fig. 2 and 3.) no part at all of the enlightened surface can be seen. At D, a little part of it is turned towards the earth, and from its figure it is then said to be horned. At C, one half of the enlightened surface is turned to the earth, and she is then said to be dichotomised, and in her first quarter or quadrature. At B, a part more than half is turned to the earth, and then she is said to be gibbous. At A, her whole illuminated hemisphere is seen, being then in opposition to the sun; and this is called the full moon. At H, she is again gibbous, but on the other part: at G she is again dichotomised, and in her last quarter: at F she is horned, as before; and then becomes new again at E, where she is in conjunction with the sun.

If M N be drawn perpendicular to the line S L joining the centers of the sun and moon, and O P perpendicular to the line T L joining the centers of the earth and moon, it is evident that the angle P L N in the first half of the orbit, and O L M in the second, will be proportional to the quantity of the illuminated disk turned towards the earth; and

this angle is every where equal to the angle E T L, which is called the elongation of the moon from the sun.

To find what quantity of the moon's visible surface is illustrated for any given time, we are to consider that the circle of illumination B F C, (fig. 4.) is oblique to the view every where, but at E and A; and therefore by the laws of the orthographic projection, it will be projected into an ellipse whose longest axis is the diameter of the moon B C, and the semi-conjugate is  $F L = \cosine$  of the angle of elongation F B P. Hence  $F P = \text{versed sine of the said angle}$ . But from the nature of the circle and ellipse, we have L P in a constant ratio to F P, wherever the line O P is drawn perpendicular to B; therefore also  $2 L P = P O$  has a constant ratio to F P. But (by Euclid V. 12.) the sum of all the lines O P  $\equiv$  area of the circle is to the sum of all the lines F P  $\equiv$  area of the illuminated part, as the diameter of the circle O P to the versed sine of the elongation F P.

As the moon illuminates the earth by a reflex light, so does the earth the moon; but the other phenomena will be different for the most part. 1. The earth will be visible but to little more than one half of the lunar inhabitants. 2. To those who see it, the earth appears fixed, or at least to have no circular motion, but only that which results from the moon's libration. 3. Those who live in the middle of the moon's visible hemisphere, see the earth directly over their heads. 4. To those who live in the extremity of that hemisphere, the earth seems always nearly in the horizon, but not exactly there, by reason of the libration. 5. The earth, in the circle of a month, would have all the same phases as the moon has. Thus the lunarians, when the moon is at E, in the middle of their night, see the earth at full, or shining with a full face; at C and G it is dichotomised, or half light and half dark; at A it is wholly dark, or new; and at the parts between these it is gibbous. 6. The earth appears variegated with spots of different magnitudes and colours, arising from the continents, islands, oceans, seas, clouds, &c. 7. These spots will appear constantly revolving about the earth's axis, by which the lunarians will determine the earth's diurnal rotation, in the same manner as we do that of the sun.

MOOR, in country affairs, denotes an unlimited tract of land, usually over-run with heath.

MOOR-BUZZARD, the English name of the yellow-legged falcon, with an iron-coloured body and yellow head.

It is about the size of the common crow, and has its English name from building its nest in moorish and boggy places.

MOOR-CKOCK, or GOR-CKOCK, a species of tetrao, with a forked tail, spotted with white underneath. It is a native of England, but very rare: the

the male is throughout of a very deep iron grey, without any variegation; and the female is likewise grey, but variegated with transverse lines of black.

**MOORING**, or **MOARING**, in the sea language, is the laying out the anchors of a ship in a place where she can ride secure.

**Mooring across**, is laying out an anchor on each side: and **mooring along**, is to have an anchor in a river, and a hawser on shore.

When ships are laid up in ordinary, or are under orders of fitting for the sea, the moorings are laid out in harbours; and consist of claws, pendant chains, cables, bridles, anchors, swivels, jewsharps, buoys, and chains.

**MOOT**, a difficult case argued by the young barristers and students at the inns of court, by way of exercise, the better to qualify them for practice, and to defend the causes of their clients.

**MORAL**, something belonging to manners, or the conduct of life.

**MORAL PHILOSOPHY**, the same with ethics. See **ETHICS**.

**MORAL SENSE**, that whereby we perceive what is good, virtuous, and beautiful in actions, manners, and characters.

**MORALITY**, the science and doctrine of morals, otherwise called ethics. See **ETHICS**.

**MORASSE**, a low, moist land, which receives the waters from the higher grounds without having any descent to carry them off.

**MORBID**, among physicians, signifies diseased or corrupt; a term applied either to an unsound constitution, or to those parts or humours that are infected by a disease.

**MORBILLI**, the measles, in medicine. See **MEASLES**.

**MORSEK**, or **MORISCO**, is a kind of painting, carving, &c. done after the manner of the moors; consisting of several grotesque pieces and compartments, promiscuously mingled, not containing any perfect figure of a man, or other animal; but a wild resemblance of birds, beasts, trees, &c.

**MORESK-DANCES**, vulgarly called morrice-dances, are those altogether in imitation of the moors, as sarabands, chacons, &c. which are generally performed with castenets or tambours.

**MORINA**, in botany, a plant of the diandria-monogynia class, with a monopetalous flower, bilabiated at the limb: the seed is single, roundish, and coronated with the cup of the flower.

**MORINDA**, in botany, a genus of the pentandria-monogynia class of plants, with an infundibuliform monopetalous flower, divided into five segments at the limb: the fruit is a roundish berry, with an umbilicated point, and contains two elliptico-hemispherical seeds.

**MORISONA**, in botany, a genus of plants, the flower of which consists of four oblong petals: the

fruit is a globose berry, containing a great many kidney-shaped seeds.

**MORNING**, the beginning of the day, the first appearance of light, or the time from midnight till noon.

**MOROCCO**, *Marroquin*, in commerce, a fine kind of leather, prepared of the skin of an animal of the goat kind, and imported from the Levant, Barbary, &c.

**MORPHEW**, a leprous kind of scurf, which sometimes breaks out upon the skin, particularly about the forehead. See **LEPROSY**.

**MORSE**, in zoology, a name by which some call the hippopotamus. See the article **HIPPOPOTAMUS**.

**MORTALITY**, or *Bills of MORTALITY*, properly denote weekly lists of the persons who die in any place.

In London, these bills are drawn up by the company of parish clerks, and contain an account of the numbers, ages, diseases, &c. of such as die within the bills of mortality; that is, in London, Westminster, and ten miles round.

The great disparity between the births and burials in London, is owing to this, that the dissenters of all sorts, baptize their children without sending an account of them to the parish clerks; so that little dependence is to be had on these, with regard to calculating annuities for life.

**MORTAR**, a preparation of lime and sand, mixed up with water, which serves as a cement, and is used by masons and bricklayers, in building of walls of stone and brick.

**MORTAR-PIECE**, a short piece of ordnance, considerably thick and wide; serving to throw bombs, carcasses, fire-pots, &c.

**MORTGAGE**, in law, a pledge or pawn of lands, tenements, &c. for money borrowed; so called, because if the money is not paid at that day, the land dies to the debtor, and is forfeited to the creditor.

The common method of making a mortgage, is by lease for a long term of years, wherein a pepper-corn rent has been usually reserved: or it may be made by assignment for a term, and by lease and release. The creditor, who holds the estate according to the condition of the deed, is called the mortgagee; but the mortgager, who is the person that makes the mortgage, generally keeps possession of the land till failure is made in the payment of the mortgage-money; in which case, though the mortgagee enters for non-payment, the mortgager has a right to the equity of redemption in the court of chancery, where he may call the mortgagee to an account for the profits of the land mortgaged.

**MORTIFICATION**, in medicine, the same with sphacelus. See **SPHACELUS**.

**MORTISE**, or **MORTOISE**, in carpentry, &c.

a kind of joint, wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

**MORTMAIN**, in law, is the alienation of lands or tenements to any religious house, corporation, or fraternity, and their successors.

**MORTUARY**, in the ecclesiastical law, is a gift left by a man at his death to his parish church, in recompence of personal tythes omitted to be paid in his life time: or it is that beast, or other cattle, which, after the death of the owner, by the custom of the place, is due to the parson or vicar, in lieu of tythes or offerings forgot, or not well and truly paid by him that is dead.

**MORUS**, the mulberry-tree, in botany. See **MULBERRY**.

**MOSAIC**, or **MOSAIC-WORK**, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square, and cemented on a ground of stucco, in such a manner as to imitate the colours and degradations of painting.

**MOSCHUS**, the musk-animal, a genus of quadrupeds of the order of the pecora, having no horns; the canine teeth of the upper jaw are exerted.

Of this genus there is only one known species, which is the animal that produces the perfume, from which it is named. See **MUSK**.

This creature, when full grown, is three feet in length, from the tip of the nose to the rump; the head is oblong, and the anterior part much like the greyhound; the ears are large and erect, they resemble those of the rabbit, and are equal in length to the diameter of the forehead; the tail is not more than two inches in length, and the creature always carries it erect; the body is tolerably fleshy, and rounded; the legs about a foot in length, and very robust; the feet deeply divided, each into two claws in the anterior part, and as many heels behind. The fur on the head and that on the legs is about half an inch long, that on the belly is an inch and a half, and that which grows on the back three inches; these hairs are thicker than in any other known animal, and are variegated, from the base to the extremity, with distinct spaces of brown and white: the vessel or bag in which the perfume (called musk) is contained, is three inches long and two broad, and hangs under the belly, protuberating near three quarters of an inch beyond the surface.

**MOSQUE**, a temple, or place of religious worship, among the mahometans.

All mosques are square buildings, generally built with stone; before the chief gate there is a square court, paved with white marble, and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there is a great number of lamps; and between these, hang many crystal rings, ostriches eggs, and other cu-

riosities, which, when the lamps are lighted, make a fine shew.

As it is not lawful to enter the mosques with shoes or stockings on, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosque, but stay in the porches without. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another: these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayer by certain officers appointed for that purpose.

Most of the mosques have a kind of hospital belonging to them, in which travellers, of what religion soever, are entertained during three days. Each mosque has also a place called *Tarbé*, which is the burying-place of its founders; within which is a tomb, six or seven feet long, covered with green velvet or satin, at the ends of which are two tapers, and round it several seats for those who read the koran, and pray for the souls of the deceased.

**MOSS**, *Muscus*, in botany, a very numerous order of plants, belonging to the cryptogamia class, the fructification of which is but little understood.

Linnæus, indeed, has attempted to arrange them according to what he takes to be the parts of generation, many of which he acknowledges to be wanting. Hence in the description of such imperfect plants, it becomes necessary to distinguish them according to their general habit and structure.

Mosses, therefore, may be arranged under the following subdivisions, 1. Such as consist of tender flexible filaments, as *byssus* and *conserva*. 2. Such as consist of a mere foliaceous or gelatinous matter, as *phyllona*, *ulva*, &c. 3. Such as consist of firm and somewhat rigid stalks, as *usnea*, *platysma*, &c. 4. Such as consist merely of a dry, crustaceous, or else of a gelatinous matter, as *placodium*. 5. Such as produce capsules, covered with opercula, as *bryum*, *polytrichum*, *sphagnum*, *mnium*, &c. 6. Such as produce capsules without pedicles, and without calyptræ, as *lycopodium*, *trispermium*, *selago*, &c. 7. Such as consist of foliaceous matter, with evident fructifications arising from it, as *marchantia*, *jungermannia*, *anthoceros*, &c. See **BYSSUS**, **CONSERVA**, &c.

Mosses are of considerable use in medicine; *usnea* is esteemed a good desiccative and astringent; the cup moss is recommended in the chin cough; the grey ground-lichen, or liverwort, against the bite of a mad-dog; and other species, in other disorders, as mentioned under their respective heads.

Moss is frequently very injurious to fruit-trees, which grow upon cold barren soils, or where they are so close planted as to exclude the free access of

the air: the only remedy, in such cases, is to cut down part of the trees, and to plough up the ground between those left remaining; and in the spring-season, in moist weather, you should, with an iron instrument made a little hollow, the better to surround the branches of the trees, scrape off the moss, carrying it off the place; and by two or three times thus cleansing them, together with carefully stirring the ground, it may be entirely destroyed from the trees; but unless part of the trees were cut down, and the ground be well stirred, the rubbish of the moss will signify little.

If the trees are covered with moss, on account of the dryness of the ground, the proper remedy is to lay mud, from the bottom of a river, pretty thick about their roots.

Moss, a name given to boggy grounds in many parts of England.

These consist of a turfy surface, below which is a black, moist, spongy earth, which being dug up with spades, somewhat in the form of bricks, and dried, is what they call peats, used as fuel in several parts, and the upper scurf being cut and dried, makes turfs, another coarser sort of fuel.

*Wall-Moss, Bryum*, in botany. See the article BRYUM.

MOSTRA, in the Italian music, a mark at the end of a line or space, to shew that the first note of the next line is in that place; and if this note be accompanied with a sharp or flat, it is proper to place these characters along with the mostra.

MOTAZALITES, the name of a famous sect among the mahometans, properly signifying separatists.

The motazalites are not accounted orthodox musfulmen, as they believe the alkoran to be created and not eternal; and besides assert, that there are no attributes in God distinct from his essence.

MOTE, in law-books, signifies court or convention, as a ward-mote, burgh-mote, swain-mote, &c. See the articles WARD-MOTE, &c.

MONETTO, in the Italian music, a sort of church-music, composed with much art and ingenuity, from one to eight parts, with or without instruments, and usually accompanied with a thorough bass.

MOTH, *Tinea*, or *Phalæna*, in zoology. See PHALÆNA.

MOTION, is defined to be the continued and successive change of place. See COMMUNICATION of Motion.

There are three general laws of motion. 1. That a body always perseveres in its state of rest, or of uniform motion in a right line, till by some external force it be made to change its state: for as body is passive in receiving its motion, and the direction of its motion, so it retains them, or perseveres in them without any change, till it be acted on by something external. From this law it appears, why we in-

quire not, in philosophy, concerning the cause of the continuation of motion or rest in bodies, which can be no other than their inertia: but if a motion begin, or if a motion already produced is either accelerated or retarded, or if the direction of the motion is altered, an inquiry into the power or cause that produces this change is a proper subject of philosophy. 2. The second general law of motion is, that the change of motion is proportional to the force impressed, and is produced in the right line in which that force acts. When a fluid acts upon a body, as water or air upon the vanes of a mill, or wind upon the sails of a ship, the acceleration of the motion is not proportional to the whole force of those fluids, but to that part only which is impressed upon the vanes or sails, which depends upon the excess of the velocity of the fluid above the velocity which the vane or sail has already acquired; for if the velocity of the fluid be only equal to that of the vane or sail, it just keeps up with it, but has no effect either to advance or retard its motion. Regard must always be had to the direction in which the force is impressed, in order to determine the change of motion produced by it: thus, when the wind acts obliquely with respect to the direction of a ship, the change of her motion is first to be estimated in the direction of the force impressed; and thence, by a proper application of mechanical and geometrical principles, the change of the motion of the ship in her own direction is to be deduced. 3. The third general law of motion is, that action and re-action are equal, with opposite directions, and are to be estimated always in the same right line. Body not only never changes its state of itself, but resists by its inertia every action that produces a change in its motion: hence when two bodies meet, each endeavours to persevere in its state, and resists any change; the one acquires no new motion, but what the other loses in the same direction; nor does this last lose any force, but what the other acquires; and hence, though by their collision, motion passes from the one to the other, yet the sum of their motions, estimated in a given direction, is preserved the same, and is unalterable by their mutual actions upon each other.

All motion may be considered absolutely or relatively. Absolute or real motion, says Mr. MacLaurin, is when a body changes its place in absolute space; and relative motion, is when a body changes its place only with relation to other bodies.

From the observation of nature, every one knows that there is motion; that a body in motion perseveres in that state, till by the action of some power it is necessitated to change it; that it is not in relative or apparent motion in which it perseveres, in consequence of its inertia, but in real or absolute motion. Thus the apparent diurnal motion of the sun and stars would cease, without the least power or force acting upon them, if the motion of the earth

earth was stopped; and if the apparent motion of any star was destroyed by a contrary motion impressed upon it, the other celestial bodies would still appear to persevere in their course. See the article INERTIA.

To make this matter still plainer, Mr. Martin observes, that space is nothing but an absolute and infinite void, and that the place of a body is that part of the immense void which it takes up or possesses: and this place may be considered absolutely, or in itself, in which case it is called the absolute place of the body; or else with regard to the place of some other body, and then it is called the relative or apparent place of the body.

Now as a motion is only the change of place in bodies, it is evident that it will come under the same distinction of absolute and relative or apparent. All motion is in itself absolute, or the change of absolute space; but, when the motions of bodies are considered and compared with each other, then are they relative and apparent only: they are relative, as they are compared to each other; and they are apparent only, inasmuch that not their true or absolute motion, but the sum or difference of the motions only is perceivable to us.

In comparing the motions of bodies we may consider them as moving both the same way, or towards contrary parts: in the first case, the difference of motion is only perceived by us; in the latter, the sum of the motions. Thus, for example, suppose two ships, A and B, set sail from the same port upon the same rhumb, and that A sails at the rate of five miles per hour, and B at the rate of three: here the difference of the velocity (viz. two miles per hour) is that by which the ship A will appear to go from the ship B forwards, or the ship B will appear at A to go with the same velocity backwards, to a spectator in either respectively.

If the two ships, A and B, move with the same degree of velocity, then will the difference be nothing, and so neither ship will appear to the other to move at all. Hence it is, that though the earth is continually revolving about its axis, yet, as all objects on its surface partake of the same common motion, they appear not to move at all, but are relatively at rest.

If two ships, A and B, with the degrees of velocity as above, meet each other, the one will appear to the other to move with the sum of both velocities, viz. at the rate of eight miles per hour; so that in this case the apparent motion exceeds the true, as in the other it fell short of it. Hence the reason why a person, riding against the wind, finds the force of it much greater than it really is, whereas, if he rides with it, he finds it less.

The reason of all these phenomena of motion will be evident, if we consider we must be absolutely at rest, if we would discern the true or real motions of

bodies about us. Thus a person on the strand will observe the ships sailing with their real velocity; a person standing still will experience the true strength and velocity of the wind; and a person, placed in the regions between the planets, will view all their true motions, which he cannot otherwise do, because in all other cases the spectator's own motion must be added to or subtracted from that of the moving body, and the sum or difference is therefore the apparent or relative motion, and not the true.

Motion is also either equable or accelerated.

Equable motion is that by which a body passes over equal spaces in equal times.

Accelerated motion is that which is continually augmented or increased, as retarded motion is that which continually decreases; and, if the increase or decrease of motion be equal in equal times, the motion is then said to be equally accelerated or retarded.

Equable motion is generated by a single impetus or stroke; thus the motion of a ball from a cannon is produced by the single action of the powder in the first moment, and, therefore, the velocity it first sets out with, would always continue the same, were it void of gravity; and to move in an unresisting medium; which, therefore, would be always equable, or such as would carry it through the same length of space in every equal part of time.

*Animal MOTION*, is that whereby the situation, figure, magnitude, &c. of the parts, &c. of animals are changed: under these are comprised all the animal functions. See the article FUNCTION.

Animal motions are divided into spontaneous and natural.

*Spontaneous* or *muscular MOTION*, is that performed by the muscles at the command of the will. See MUSCLE.

*Natural* or *involuntary MOTION*, that effected, without any such command, by the mere mechanism of the parts, such as the motion of the heart, pulse, &c.

*Intestine MOTION*, the agitation of the particles of which a body consists.

Some philosophers will have every body, and every particle thereof in continual motion. Hence intestine motion is represented to be a motion of the internal and smaller parts of matter, continually excited by some external latent agent, which only discovers itself by effects, being appointed by nature as the great instrument of the changes in bodies.

*MOTION*, in astronomy, peculiarly denotes the orderly courses of the heavenly bodies.

The motions of the celestial luminaries are diurnal or common, and secondary or proper.

*Diurnal* or *primary MOTION*, is that wherein the whole mundane sphere appears to revolve every day round the earth from east to west. See the article DIURNAL.

# M O U

This is called the motion of the primum mobile, and the common motion, to distinguish it from that peculiar to each planet, &c.

*Secondary or proper MOTION*, is that wherewith a star, planet, &c. advances a certain space every day from west towards east. See the article EARTH, &c.

*MOTION*, in music, the manner of beating the measure, to hasten or slacken the time of the words or notes. See TIME.

*MOTIONS*, in war, the marches, counter-marches, &c. of an army in changing its post.

*MOTTO*, in armoury, a short sentence or phrase carried in a scroll, generally under, but sometimes over the arms; sometimes alluding to the bearing, sometimes to the name of the bearer, and sometimes containing whatever pleases the fancy of the diviser.

*MOTU*. See the article EX MERO MOTU.

*MOVEABLE*, in general, denotes any thing capable of being moved.

The moveable feasts are such as are not regularly held on the same day of the year or month, though they are always on the same day of the week. Thus Easter, which is that moveable feast on which all the rest depend, is held on the Sunday which falls upon, or next after, the first full moon following the 21st of March; and all the other feasts keep a regular and certain distance from it; such as Septuagesima, Sexagesima, Ash-wednesday, Ascension-day, &c. which see under their proper articles.

The moveable terms are Easter-term and Trinity-term. See TERMS.

*MOVEABLE GOODS*, in law, such chattels as are capable of being removed from one place to another, as cattle, merchandize, &c. See CHATTELS.

*MOVEMENT*, in mechanics, a machine that is moved by clockwork; for the theory of which, see the articles CLOCK, WATCH, &c.

To make a regular movement, that may serve to measure time as exactly as possible, is one of the most valuable problems in mechanics, which has been most successfully effected, hitherto, by adapting pendulums to clocks: though it must be owned, says Mr. Maclaurin, that many ingenious contrivances have been invented to correct the irregularities of those movements that go by springs.

*MOULD*, or *MOLD*, in the mechanic arts, &c. a cavity cut with a design to give its form or impression to some softer matter applied therein, of great use in sculpture, foundery, &c.

*MOULDS*, in the manufacture of paper, are little frames composed of several brass or iron-wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened; these moulds are more usually called frames, or forms.

# M O U

*Furnace and Crucible-makers MOULDS*, are made of wood, of the same form with the crucibles; that is, in form of a truncated cone: they have handles of wood to hold and turn them with, when, being covered with the earth, the workman has a mind to round or flatten his vessel.

*MOULDS for Leadens Bullets*, are little iron pin-cers, each of whose branches terminates in an hemispherical concavity, which when shut, form an intire sphere: in the lips or sides where the branches meet, is a little jet or hole, through which the melted led is conveyed.

*Glaziers-MOULDS*. The glaziers have two kinds of moulds, both serving to cast their lead. In the one they cast the lead into long rods or canes, fit to be drawn through the vice, and the grooves formed therein: this they sometimes call ingot-mould. In the other they mould those little pieces of lead a line thick, and two lines broad, fastened to the iron-bars: these may be also cast in the vice.

*Goldsmiths-MOULD*. The goldsmiths use the bones of the cuttle-fish to make moulds for their small works, which they do by pressing the pattern between two bones, and leaving a jet or hole to convey the silver through, after the pattern has been taken out.

*MOULD*, among masons, a piece of hard wood or iron hollowed withinside, answering to the contours of the mouldings or corniches, &c. to be framed; this is otherwise called calibrer.

*MOULDS*, among plumbers, are the tables whereon they cast the sheets of lead. These they sometimes call simple tables: besides which they have other real moulds wherewith they cast pipes without soldering. See PLUMBERY.

*MOULDS*, among tallow-chandlers, are of two kinds: the first for the common dipped candles, being the vessel wherein the melted tallow is disposed, and the wick dipped: this is of wood, of a triangular form, and supported on one of its angles, so that it has an opening of near a foot at top: the other, used in the fabric of mould candles, is of brass, pewter, or tin; here each candle has its several moulds. See CANDLE.

*MOULD*, among gold-beaters, a certain number of leaves of vellom, or pieces of guts, cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver, which they beat on the marble with the hammer. They have four kinds of moulds, two whereof are of vellom, and two of gut; the smallest of those of vellom consists of forty or fifty leaves, the largest contains an hundred; for the others, each contains five hundred leaves. The moulds have all their several cases, consisting of two pieces of parchment, serving to keep the leaves of the mould in their place, and prevent their being disordered in beating.

*MOULD*,

**MOULD**, in agriculture, a loose kind of earth, every where obvious on the surface of the ground, called also natural or mother-earth; by some also loam. See **EARTH**.

**MOULDINESS**, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface, which, viewed through a microscope, appears like a kind of meadow, out of which arise herbs and flowers, some only in the bud, others full blown, and others decayed, each having its root, stalk, and other parts.

**MOULDING**, any thing cast in a mould, or that seems to have been so, though in reality, it were cut with a chissel, or the ax.

**MOULDING**, in architecture, projectures beyond the naked wall, column, wainscot, &c. the assemblage of which forms corniches, door-cases, and other decorations of architecture.

**MOULDING**, in ship-building, the juttings or projectures beyond the level of the side; they are placed above one another; the intervals of which are generally ornamented with martial instruments, trophies of war, marine and other emblematical figures, &c.

**MOULINET**, in mechanics, is used to signify a roller, which, being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature, to draw ropes, and heave up stones, &c.

**MOULINET** is also a kind of turnstile, or wooden cross, which turns horizontally upon a stake fixed in the ground; usually placed in passages to keep out horses, and to oblige passengers to go and come one by one. These moulins are often set near the outworks of fortified places, at the sides of the barriers, through which people pass on foot.

**MOULTING**, or **MEWING**. See the article **MEWING**.

**MOUND**, a term used for a bank or rampart, or other fence, particularly that of earth.

**MOUND**, in heraldry, a ball or globe with a cross upon it, such as our kings are usually drawn with, holding it in their left hands, as they do the sceptre in the right.

**MOUNT-EGG**. In the tin-works, after the tin from the burnt ore is melted down and remelted, there will sometimes remain a different slug in the bottom of the float; this they call mount-egg: and though of a tin colour, yet is of an iron nature, as has been found by applying a magnet to it.

**MOUNTAIN**, *Mons*, a part of the earth, rising to a considerable height above the level of the surface thereof.

*Burning-Mountain*. See **VULCANO**.

**MOUNTING**, in the mechanic arts, something that serves to raise or set off a work: thus, the frame and its dependences make the mounting of a look-

ing-glass; the hilt, the mounting of a sword; the fust, or but, the mounting of a carabine, musquet, &c. and the mounting of a fan, is the sticks which serve to open and shut it.

**MOUNTING**, in military affairs, signifies going upon duty: thus, mounting a breach, is running up to it; mounting the guard, is going upon guard; and mounting the trenches, is going upon duty in the trenches: but mounting a cannon, mortar, &c. is the setting it on its carriage, or the raising its mouth.

**MOUSE**, among sailors, a sort of rising made on the stays, and some other ropes, in a ship, to prevent the eye, in one end of the rope, from slipping up above its proper place, or the body of it.

The mouse, which somewhat resembles a pear, is raised by winding tarred canvas, called parling, about the stay in one place, and afterwards a great many turns of spun-yarn: the whole is completed by weaving a coat or cover round the mouse very curiously, which is called pointing. See the article **POINTING**.

**MOUSE-EAR**, *Myosotis*, in botany. See the article **MYOSOTIS**.

**MOUTH**, in anatomy, a part of the face, consisting of the lips, the gums, the insides of the cheeks, the palate, the salival glands, the os hyoides, the uvula, and the tonsils; which see under their proper articles.

**MOXA**, a sort of cotton or downy substance, separated from the leaves of a sort of Indian mugwort; used by the eastern nations for cauterizing in certain parts of the body.

**MUCILAGE**, in pharmacy, is in general any viscid and glutinous liquor.

**MUCILAGE** also denotes a thick pituitous matter, evacuated with the urine, in the gravel and dysuria.

**MUCILAGE** likewise imports the liquor which principally serves to moisten the ligaments and cartilages of the articulations; and is supplied by the

**MUCILAGINOUS GLANDS**, in anatomy, a very numerous set of glands, serving to secrete the mucilage of the joints. See **GLAND**.

**MUCOR**, in botany, a genus of mushrooms, being funguses consisting of little roundish bladders, in which are found numerous seeds, affixed to hair-like receptacles, placed all over the inside of the bladders.

**MUCOUS GLANDS**, in anatomy three glands which empty themselves into the urethra; so called by their first discoverer, Mr. Cowper, from the tenacity of the liquor which they separate.

**MUCRO CORDIS**, in anatomy, the lower or pointed end of the heart.

**MUCUS**, a mucilaginous liquor, separated by the mucous glands and the nostrils.

**MUFFLE**, in metallurgy, an arched cover, resisting the strongest fire, and made to be placed over cop-

coppels and tests, in the operations of assaying, to preserve them from the falling of coals and ashes into them; though, at the same time, of such a form, as is no hindrance to the action of the air and fire on the metal, nor to the inspection of the assayer.

The muffles may be made of any form, providing they have these conditions: but those used with coppels are commonly made semi-cylindrical; or when greater vessels are employed, in form of a hollow hemisphere. The muffle must have holes, that the assayer may look in; and the fore-part of it must be always quite open, that the air may act better in conjunction with the fire, and be incessantly renewed: the apertures in the muffle serve also for the regimen of the fire, for the cold air rushing into the large opening before, cools the bodies in the vessel; but if some coals are put in it, and its aperture before be then shut, with a door fitted to it, the fire will be increased to the highest degree, much more quickly than it can be by the breathing holes of the furnace.

**MUFTI**, or **MUPHTI**, the chief of the ecclesiastical order, or primate, of the mussulman religion.

**MUGGLETONIANS**, a religious sect, which arose in England about the year 1657; so denominated from their leader, Lodowick Muggleton, a journeyman taylor, who, with his associate Reeves, set up for great prophets; pretending, as it is said, to have an absolute power of saving and damning whom they pleased; and giving out, that they were the two last witnesses of God, that should appear before the end of the world.

**MUGWORT**, *Artemisia*, in botany. See **ARTEMISIA**.

**MULBERRY-TREE**, *Morus*, in botany, a genus of plants of the monoecia-triandria class; the male flowers are collected in a long amentum, having no corolla: the stamina are four erect subulated filaments, longer than the cup, and terminated with simple antheræ: the female flowers have no petals; they are collected in round heads, and are succeeded by a well-known, large, fleshy, succulent berry, composed of several protuberances, in each of which is placed an oval pointed seed.

Of mulberries, there are two kinds, the black and the white; but the black is most common with us. They are propagated by sowing the seeds, or by laying down the fruit-bearing branches; but those propagated by seeds are commonly most vigorous, though they seldom prove so fruitful as the others. They may also be increased from cuttings, planted in March.

The soil mulberry-trees delight in, is a rich light earth, of a good depth; they should never be planted near other trees or buildings, for then the fruit will not ripen so well.

Mulberries have the qualities common to other

sweet fruits, in abating heat and quenching thirst; they are chiefly eaten for pleasure, but they yield little nourishment.

The leaves of this plant are used in France, Italy, Persia, &c. for feeding silk-worms; for which purpose, they should never be allowed to grow tall, but kept in a sort of hedge; and instead of pulling off the leaves singly, they should be cut off with sheers, together with the young branches.

**MULCT**, a fine of money laid upon a man, who has committed some fault or misdemeanor.

**MULCH**, a term used by gardeners for rotten dung, or the like, thrown upon beds of young plants, to preserve them from the bad effects of cold or drought.

**MULE**, in zoology, a mongrel kind of quadruped, usually generated between an ass and a mare, and sometimes between a horse and a she-ass.

The mule is a sort of a monster, of a middle nature between its parents, and therefore incapable of propagating its species; so careful is nature to avoid filling the world with monsters.

Mules are chiefly used in countries where there are rocky and stony roads, as about the Alps, Pyrenees, &c.

**MULLEIN**, *Verbascum*, in botany. See **VERBASCUM**.

**MULLER**, or **MULLAR**, denotes a stone flat and even at the bottom, but round at top, used for grinding matters on a marble.

The apothecaries use mullers to prepare some of their testaceous powders, and painters for their colours, either dry or in oil.

**MULLER** is also an instrument used by the glass-grinders; being a piece of wood, to one end whereof is cemented the glass to be ground: it is ordinarily about six inches long, turned round.

**MULLET**, *Mugil*, in ichthyology, a genus of the acanthopterygeous fishes, the head of which is of a depressed form in the anterior part, and the body oblong and compressed. On each side of the head, below the nostrils, there stands a little bone, which is serrated on its lower part: the eyes are not covered with a skin: and there are teeth on the tongue and palate, but none in the jaws or fauces: the branchiostege membrane on each side contains six ossicles; these are of a crooked figure, and the upper one, which is the broadest, is covered by the coverings of the gills in such a manner, that only five appear.

**MULLET**, or **MOLLET**, in heraldry, a bearing in form of a flat, or rather of the rowel of a spur, which it originally represented.

The mullet has but five points; when there are six, it is called a star; though others make this difference, that the mullet is, or ought to be, always pierced, which a star is not.

The mullet is usually the difference or distinguishing

ing mark for the fourth son, or third brother, or house; though it is often borne alone, as coat-armour.

**MULTANGULAR**, a figure, or body, which has many angles.

**MULTILATERAL**, in geometry, is applied to those figures which have more than four sides or angles, more usually called polygons. See the article **POLYGON**.

**MULTINOMIAL**, or **MULTINOMIAL ROOTS**, in mathematics, such roots as are composed of many names, parts, or members; as  $a + b + d + c$ , &c. See the article **ROOT**.

**MULTIPLE**, *Multiplex*, in arithmetic, a number which comprehends some other several times; thus 6 is a multiple of 2, and 12 is a multiple of 6, 4, and 3, comprehending the first twice, the second thrice, &c.

**MULTIPLE RATIO**, or **PROPORTION**, is that which is between multiples. If the lesser term of the ratio be an aliquot part of the greater, the ratio of the greater to the less is called multiple; and that of the less to the greater submultiple. A submultiple number is that contained in the multiple; thus the numbers 1, 2, and 3, are submultiples of 6. Duple, triple, &c. ratios, as also subduples, sub-

triples, &c. are so many species of multiple and submultiple ratios. See **RATIO**.

**MULTIPLICAND**, in arithmetic, one of the factors in the rule of multiplication; being that number which is given to be multiplied by another, which is called the multiplier, or multiplier.

**MULTIPLICATION**, in general, the act of increasing the number of any thing.

**MULTIPLICATION**, in arithmetic, is a rule, by which any given number may be speedily increased, according to any proposed number of times.

Multiplication, which is the fourth rule in arithmetic, serves instead of many additions; the product of a multiplication being only the repetition of the multiplicand, so many times as there are units in the multiplier.

**Case I.** To multiply single numbers by one another.

All the variety that can happen in this case, is expressed in the following table of multiplication, which must be perfectly got by heart, for the ready performance of any operation in multiplication: thus we learn, by the table, that 3 times 3 is 9; that 3 times 6 is 18, &c. We have in this table, omitted multiplying with 2, it being so very easy that any one may do it.

MULTIPLICATION TABLE.

|                   |                   |                   |                   |                   |                   |
|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|
| $3 \times 3 = 9$  | $4 \times 4 = 16$ | $5 \times 5 = 25$ | $6 \times 6 = 36$ | $7 \times 7 = 49$ | $8 \times 8 = 64$ |
| $3 \times 4 = 12$ | $4 \times 5 = 20$ | $5 \times 6 = 30$ | $6 \times 7 = 42$ | $7 \times 8 = 56$ | $8 \times 9 = 72$ |
| $3 \times 5 = 15$ | $4 \times 6 = 24$ | $5 \times 7 = 35$ | $6 \times 8 = 48$ | $7 \times 9 = 63$ | $9 \times 9 = 81$ |
| $3 \times 6 = 18$ | $4 \times 7 = 28$ | $5 \times 8 = 40$ | $6 \times 9 = 54$ |                   |                   |
| $3 \times 7 = 21$ | $4 \times 8 = 32$ | $5 \times 9 = 45$ |                   |                   |                   |
| $3 \times 8 = 24$ | $4 \times 9 = 36$ |                   |                   |                   |                   |
| $3 \times 9 = 27$ |                   |                   |                   |                   |                   |

**Case II.** To multiply a compound number by a single one.

**Rule.** Having placed the multiplier under the unit's place of the multiplicand; first, multiply the unit of the multiplicand by the multiplier; if their product be less than ten, set it down underneath its own place of units, and proceed to the next figure of the multiplicand: but if their product be above ten, or tens, then set down the overplus only, or odd figure, as in addition, and carry the said ten or tens in mind, till you have multiplied the next figure of the multiplicand with the multiplier: then, to their product add the ten or tens beared in mind, setting down the overplus of their sum above the tens, as before; and so proceed in that manner till all the figures of the multiplicand are multiplied with the multiplier.

**Example.** Suppose it were required to multiply 3213 by 3.

$$\begin{array}{r} 3213 \text{ Multiplicand.} \\ 3 \text{ Multiplier.} \\ \hline 9639 \end{array}$$

For, beginning at the unit's place 3, say, 3 times 3 is 9, which, because it is less than ten, set down underneath its own place, and proceed to the next place of tens, saying 3 times 1 is 3, which set down underneath its own place; then at the next place, viz. of hundreds, say, 3 times 2 is 6, which set down as before; lastly, at the place of thousands, say, 3 times 3 is 9, which being set down underneath its own place, the operation is finished, and the true product is 9639.

**Case III.** To multiply one compound number by another.

**Rule.** Place every number respectively under its own kind; multiply each figure of the multiplicand by each figure of the multiplier as before; and observe to set the first figure of each respective product under that figure of the multiplier, by which it was made; lastly, add the several products together for the whole product.

**Example**

# M U L

Example 1. Let it be required to multiply 78094 by 7563.

78094 Multiplicand.

7563 Multiplier.

- 234282 The first particular product with 3.  
468564 The second particular product with 60.  
390470 The third particular product with 500.  
546658 The 4th particular product with 7000.  
590624922 The total, or true product required.

When there is a cypher or cyphers to the right hand, either of the multiplicand or multiplier, or to both, in that case, multiply the figures as before, neglecting the cyphers until the particular products are added together; then to their sum annex so many cyphers as there are in either or both the factors, as in the following examples:

| Example 2. | Example 3. | Example 4.  |
|------------|------------|-------------|
| 9538       | 87600      | 785000      |
| 4600       | 79         | 56900       |
| 57228      | 7884       | 7065        |
| 38152      | 6132       | 4710        |
| 43874800   | 6920400    | 3925        |
|            |            | 44666500000 |

If it be required to multiply any number by 10, 100, 1000, 10000, &c. it is only annexing the cyphers of the multiplier to the figures of the multiplicand, and the work is done: thus  $578 \times 10 = 5780$ ,  $578 \times 100 = 57800$ ,  $578 \times 1000 = 578000$ ,  $578 \times 10000 = 5780000$ , &c. If a quantity be multiplied by the component part of the multiplier, the product will be the same as if it had been multiplied by the multiplier itself: thus, 245 by 7, and the product by 6 is the same as if 245 was multiplied by  $7 \times 6$ , that is, by 42.

For the proof of multiplication, it is to be observed, that the product is then right when being divided by the multiplier it quotes the multiplicand; or divided by the multiplicand it quotes the multiplier. See DIVISION.

*Cross* MULTIPLICATION, otherwise called duodecimal arithmetic, is an expeditious method of multiplying things of several species or denominations, by others likewise of different species, &c. viz. shillings and pence, by shillings and pence; feet and inches, by feet and inches.

This is much used in measuring, &c. and the method is thus:

Suppose 5 feet 3 inches to be multiplied by 2 feet 4 inches; say, 2 times 5 feet is 10 feet, and 2 times 3 is 6 inches; again, say, 4 times 5 is 20 inches, or 1 foot 8 inches; and 4 times 3 is 12 parts, or 1 inch: the whole sum makes 12 feet 3 inches. In the same manner you may manage shillings and pence, &c.

# M U L

For the multiplication of vulgar and decimal fractions, see FRACTION and DECIMAL.

MULTIPLICATION, in algebra. The general rule for the signs is, that when the signs of the factors are alike (*i. e.* both + or both -) the sign of the product is +; but when the signs of the factors are unlike, the sign of the product is -.

Case 1. When any positive quantity,  $+a$ , is multiplied by any positive number,  $+n$ , the meaning is, that  $+a$  is to be taken as many times as there are units in  $n$ ; and the product is evidently  $+na$ .

Case 2. When  $-a$  is multiplied by  $n$ , then  $-a$  is to be taken as often as there are units in  $n$ ; and the product must be  $-na$ .

Case 3. Multiplication by a positive number implies a repeated addition: but multiplication by a negative implies a repeated subtraction. And, when  $+a$  is to be multiplied by  $-n$ , the meaning is that  $+a$  is to be subtracted as often as there are units in  $n$ : therefore the product is negative, being  $-na$ .

Case 4. When  $-a$  is to be multiplied by  $-n$ , then  $-a$  is to be subtracted as often as there are units in  $n$ ; but to subtract  $-a$  is equivalent to adding  $+a$ , consequently the product is  $+na$ . The second and fourth cases may be illustrated in the following manner:

It is evident that  $+a - a = 0$ ; therefore if we multiply  $+a - a$  by  $n$ , the product must vanish or be 0, because the factor  $a - a$  is 0. The first term of the product is  $+na$  (by case 1.) Therefore, the second term of the product must be  $-na$ , which destroys  $+na$ ; so that the whole product must be  $+na - na = 0$ . Therefore,  $-a$  multiplied by  $+n$  gives  $-na$ .

In the like manner, if we multiply  $+a - a$  by  $-n$ , the first term of the product being  $-na$ , the latter term of the product must be  $+na$ , because the two together must destroy each other, or their amount 0, since one of the factors (*viz.*  $a - a$ ) is 0. Therefore,  $-a$  multiplied by  $-n$  must give  $+na$ .

If the quantities to be multiplied are simple, find the sign of the product by the last rule; after it place the product of the co-efficients, and set down all the letters after one another as before.

## EXAMPLES.

|            |       |         |
|------------|-------|---------|
| Mult. $+a$ | $-2a$ | $+6x$   |
| By $+b$    | $+4b$ | $-5a$   |
| Product    | $+ab$ | $-8ab$  |
|            |       | $-30ax$ |

|             |           |
|-------------|-----------|
| Mult. $-8x$ | $+3ab$    |
| By $-4a$    | $-5ac$    |
| Product     | $+32ax$   |
|             | $-15aabc$ |

To multiply compound quantities, you must multiply every part of the multiplicand by all the parts of the multiplier taken one after another, and then collect

collect all the products into one sum : the sum shall be the product required.

$$\begin{array}{r|l} \text{Mult. } a + b & 2a - 3b \\ \text{By } a + b & 4a + 5b \\ \hline \text{Prod. } \left\{ \begin{array}{l} aa + ab \\ + ab + bb \end{array} \right\} & \left\{ \begin{array}{l} 8aa - 12ab \\ + 10ab - 15bb \end{array} \right\} \\ \hline \text{Sum } & aa + 2ab + bb \quad 8aa - 2ab - 15bb \end{array}$$

$$\begin{array}{r|l} \text{Mult. } 2a - 4b & xx - ax \\ \text{By } 2a + 4b & x + a \\ \hline \text{Prod. } \left\{ \begin{array}{l} 4aa - 8ab \\ + 8ab - 16bb \end{array} \right\} & \left\{ \begin{array}{l} xxx - axx \\ + axx - aax \end{array} \right\} \\ \hline \text{Sum } & 4aa \dots 0 - 16bb \quad xxx \dots 0 - aax \end{array}$$

$$\begin{array}{r|l} \text{Mult. } aa + ab + bb & \\ \text{By } a - b & \\ \hline \text{Prod. } \left\{ \begin{array}{l} aaa + aab + abb \\ - abb - abb - bbb \end{array} \right\} & \\ \hline \text{Sum } & aaa \dots 0 \dots 0 \dots 0 - bbb \end{array}$$

Products that arise from the multiplication of 2, 3, or more quantities, as  $abc$ , are said to be of 2, 3, or more dimensions; and those quantities are called factors or roots.

If all the factors are equal, then these products are called powers; as  $aa$  or  $aaa$  are powers of  $a$ . Powers are expressed sometimes by placing, above the root to the right hand, a figure expressing the number of factors that produce them. thus:

$$\left. \begin{array}{l} a \\ aa \\ aaa \\ aaaa \\ aaaaa \end{array} \right\} \left\{ \begin{array}{l} 1^{\text{st}} \\ 2^{\text{d}} \\ 3^{\text{d}} \\ 4^{\text{th}} \\ 5^{\text{th}} \end{array} \right\} \begin{array}{l} \text{power of the root } a, \\ \text{and is generally ex-} \\ \text{pressed thus:} \end{array} \left\{ \begin{array}{l} a \\ a^2 \\ a^3 \\ a^4 \\ a^5 \end{array} \right.$$

These figures which express the number of factors that produce powers are called their indices or exponents; thus 2 is the index of  $a^2$ . And powers of the same root are multiplied by adding their exponents thus:  $a^2 \times a^3 = a^5$ ,  $a^4 \times a^3 = a^7$ ,  $a^3 \times a = a^4$ .

Sometimes it is useful not actually to multiply compound quantities, but to set them down upon the sign of multiplication ( $\times$ ) between them, drawing a line over each of the compound factors. Thus  $a + b \times a - b$  expresses the product of  $a + b$  multiplied by  $a - b$ .

MULTIPLICATION of surds. See SURDS.

MULTIPLICATOR, or MULTIPLIER, in arithmetic, a number multiplying another called the multiplicand.

The larger number is generally made the multiplicand, and is placed above the smaller, or multiplier: but the result is the same, which soever of the numbers be made multiplicand, or multiplier.

MULTIPLYING-GLASS, in optics, one wherein objects appear increased in number.

It is otherwise called a polyhedron, being ground into several planes, that make angles with each

other; through which the rays of light issuing from the same point undergo different refractions, so as to enter the eye from every surface in a different direction.

MULTISILICOUS PLANTS, those which have after each flower many distinct, long, slender, filiquæ, or pods, in which their seed is contained: such are bear's-foot, columbine, house-leek, navel-wort, orpine, &c.

MULTITUDE, an assemblage, or collection of a great number of distinct persons or things.

MULTIVALVES, in natural history, the name of a general class of shell-fish; distinguished from the univalves, which consist of only one shell, and the bivalves, which consist of two; by their consisting of three or more shells.

MUM, a kind of malt-liquor, much drank in Germany; and chiefly brought from Brunswick, which is the place of most note for making it. The process of brewing mum, as recorded in the town-house of that city, is as follows: Take sixty-three gallons of water that has been boiled till one-third part is consumed, and brew it with seven bushels of wheaten-malt, one bushel of oat-meal, and one bushel of ground beans; when it is tunned, the hogthead must not be filled too full at first; as soon as it begins to work, put into it three pounds of the inner rind of fir; one pound of the tops of fir and beach; three handfuls of carduus benedictus; a handful or two of the flowers of rosa folis; add burnet, betony, marjoram, avens, penny-royal, and wild thyme, of each a handful and a half; of elder-flowers, two handfuls or more; seeds of cardamum bruised, thirty ounces; barberries bruised, one ounce: when the liquor has worked a while, put the herbs and seeds into the vessel; and, after they are added, let it work over as little as possible; then fill it up: lastly, when it is stopped, put into the hogthead ten new-laid eggs unbroken: stop it close, and drink it at two years end. Our English brewers, instead of the inner rind of fir, use cardamum, ginger, and saffras; and also add elecampane, madder, and red-sanders. Mum, on being imported, pays for every barrel 11. 5s.

MUMMY, a body embalmed or dried, in the manner used by the ancient Egyptians: or the composition with which it is embalmed.

MUMMY, among gardeners, a kind of wax used in grafting and planting the roots of trees, made in the following manner: Take one pound of black pitch, and a quarter of a pound of turpentine; put them together into an earthen pot, and set them on fire in the open air, holding something in your hand to cover and quench the mixture in time, which is to be alternately lighted and quenched till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the composition is then to be set by for use.

**MUNDIC**, in natural history, a metallic mineral, more commonly called marcasite.

**MUNICIPAL**, in the Roman civil law, an epithet which signifies invested with the rights and privileges of Roman citizens.

**MUNIMENTS**, or **MINIMENTS**, the writings relating to a person's inheritance, by which he is enabled to defend his title to his estate: or, in a more general sense, all manner of evidences, such as charters, feofments, releases, &c.

**MUNIMENT-HOUSE**, a little strong room in a cathedral, college, or university, destined for keeping the seal, charters, &c. of such cathedral, college, &c.

**MUNIONS**, in architecture, are the short, upright posts or bars which divide the several lights in a window-frame.

**MUNITION**, the provisions with which a place is furnished in order for defence; or that which follows a camp for its subsistence.

**MUNITION-SHIPS**, are those that have stores on board in order to supply a fleet of men of war at sea. In an engagement, all the munition ships, and victuallers attending the fleet, take their stations in the rear of all the rest; they are not to engage in the fight, but to attend such directions as are sent them by the admiral.

**MUNTINGIA**, in botany, a genus of plants whose flower consists of five roundish patent petals inserted in the cup; the stamina are a great number of very short capillary filaments, topped with roundish antheræ. The fruit is a globose, umbilicated berry, containing a great many very small roundish seeds.

**MURAGE**, a toll taken of every cart or horse coming laden into a city, for repairing the walls.

**MURAL**, in general, any thing belonging to a wall, which the Latins call murus.

**MURAL ARCH**, is a wall, or walled arch, placed exactly in the plane of the meridian, for fixing a large quadrant, sextant, or other instrument, in order to observe the meridian altitudes of the heavenly bodies.

**MURDER**, or **MURTHUR**, in law, is the wilful and felonious killing a person from premeditated malice; provided the party wounded or otherwise hurt, die within a year and a day after the fact was committed.

**MURDERERS**, or **MURDERING PIECES**, in a ship, are small pieces of ordnance, either of brass or iron, which have chambers put in at their breeches. They are used at the bulk-heads of the fore-castle, half-deck, or steerage, in order to clear the deck, on the ship's being boarded by an enemy.

**MUREX**, in natural history, a genus of univalve or simple shells, without any hinge, formed of a single piece, and beset with tubercles or spines: the mouth is large and oblong, and has an expanded lip, and the clavicle is rough.

**MURRAIN**, or **GARGLE**, a contagious disease among cattle, principally caused by a hot dry season, or rather by a general putridification of the air, which begets an inflammation of the blood, and a swelling in the throat, that soon prove mortal, and is communicated from one to another, though it generally goes no farther than to those of the same kind.

The symptoms of this disease are a hanging down and swelling of the head, abundance of gum in the eyes, rattling in the throat, a short breath, palpitation at the heart, staggering, a hot breath, and a shining tongue.

In order to prevent this disease, the cattle should stand cool in summer, have plenty of good water; all carrion should be speedily buried; and as the feeding of cattle in wet places, on rotten grass and hay, often occasions this disease, dry and sweet fodder should be given them. The following receipt is much recommended for the cure of this disease in black cattle: Take diapente, a quarter of an ounce; dialthæa or marshmallows, London treacle, mithridate and rhubarb, of each the quantity of a nut; of saffron a small quantity; wormwood, and red sage, of each an handful; and two cloves of garlic: boil all together in two pints of beer, till it be reduced to a pint and a half, and give it the beast luke warm, while fasting: half the proportion will serve for a cow. They must be kept warm, and take a mash of ground malt, drinking warm water for a week, and sometimes have boiled oats. If sheep are troubled with this distemper, give them a few spoonfuls of brine, and then a little tar.

**MURREY**, in heraldry, a kind of purple colour.

**MUSA**, the plantain tree, in botany. See the article **PLANTAIN**.

**MUSCADINE**, a rich kind of wine, of the growth of Provence and Languedoc, in France.

**MUSCARI**, musk hyacinth, in botany, a genus of plants, whose flower consists of an oval pitcher-shaped petal, reflexed at the brim with three nectariums and six subulated filaments, topped with antheræ coalescing together. The fruit is a roundish, trigonal capsule, having three cells, which contain several roundish seeds.

**MUSCLE**, *Musculus*, in anatomy, a part of the human body, destined to move some other part, and that in general by a voluntary motion, or such as is dictated by the will; being composed principally of flesh and tendinous fibres, which have also vessels of all kinds, as arteries, veins, nerves, and lymphatics; all which are surrounded by, or enclosed in, one common membrane.

The muscular fibres are, according to the action they are intended for, of various directions; some straight, others oblique, transverse, annular, and spiral. Some consist of one uniform series of fibres, and on that account are called simple; others are composed of various, and often contrary courses of fibres,

fibres, and these being closely arranged together, the large one seems to be made up of a number of lesser muscles, and is therefore called compound; and the more of these clusters of fibres, or smaller vessels, enter into the composition of a larger one, the thicker and stronger it is.

A muscle is divided, by anatomists, into the body, and the two extremities: the body is also called the venter or belly of the muscle; and the two extremities, if white, are called tendons.

That extremity where the muscle arises, is called its head, caput; or its beginning, origin, or fixed point: and its other extremity, or end, is called its tail, moveable point, and often its tendon; and, finally, if this be broad and membranous, it is called an aponeurosis.

In many of the muscles, both the extremities are moveable; in these, that part which of the two is least moveable, is always called the head, and the more moveable part the tail. This, however, cannot be done universally; since there are cases in which that extremity of a muscle, which was before the moveable point, becomes the fixed point; and *vice versa*, as in the *ferrati antichi*, and some of the muscles of the abdomen, not to mention any others.

*Action of the MUSCLES.* This consists in the contraction of its belly, after whatever manner that is done: by this means its extremities approach towards each other; and, by this means also, the part in which the end of the muscle is inserted, moves as if it were drawn by a cord. Schelhammer is of opinion, that this contraction of the belly of the muscle is effected by a corrugation of the fibres, in the same manner as we see an earth-worm shorten and contract itself by corrugating its skin, &c. Morgagni, on the other hand, alleges, that in order to understand the power of motion in a muscle, we ought to attend to Wallis's experiment; by which it is evidently proved, that the smallest force imaginable of the air, driven through a cylindric tube into a bladder, will, by distending its width, and shortening its length, cause it to rise up, and sustain a weight of sixty or seventy pounds.

Others have demonstrated, from hydrostatical principles, that a very small quantity of a fluid, directed through a small cylindric tube, placed in a vessel of a larger base, and already filled, will be able, in the same manner, to move and raise up a large weight; from whence they conclude, that the belly of a muscle swells in the time of its contraction or action; and that this intumescence may, nay and must, have very great effects.

Among the muscles, there are different ones that conspire in the same action, and so perform the same motion as associates: such are the flexors or extensors of the arm, and the like: hence these, and such others as conspire in the same manner to the same action, are called by authors *focii* and *congeneres*.

When, on the other hand, we regard the contrary actions of certain muscles, as the extensors of any part which act quite contrary to the flexors, these are called antagonist muscles; in this case both the kinds acting together, render the limbs rigid or immoveable: this action of the muscles is called *motus tonicus*.

*MUSCLE, Mytilus*, in natural history, a shell composed of two valves, of an oblong figure, and shutting close all the way; the valves are both convex, and of a similar shape: and the animal inhabiting it is called a tethys.

*MUSCOVY-GLASS*, in natural history, the white shining specularis with large and broad leaves, otherwise called *islinglass*. See the article *SPECULARIS*.

*MUSCULAR*, or *MUSCULOUS*, in anatomy, something relating to, or partaking of the nature of a muscle. see the article *MUSCLE*.

*MUSEUM*, a name which originally signified a part of the palace of Alexandria, which took up at least one fourth of that city. This quarter was called the museum, from its being set apart for the muses and the study of the sciences. Here were lodged and entertained the men of learning, who were divided into many companies or colleges, according to the sciences of which they were the professors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelphus, who here placed his library. Hence the word museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

*MUSES*, certain fabulous divinities amongst the pagans, supposed to preside over the arts and sciences: for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid.

*MUSHROOM, Fungus*, in botany, a genus of imperfect plants, composed of a pedicle, crowned with a broad head, convex and smooth at the top; and hollow, foliated, lamellated, or fistulous on the under side.

Mushrooms are by many supposed to be produced from the putrefaction of the dung in which they are found; but notwithstanding this notion is pretty generally received among the unthinking part of mankind, yet, by the curious naturalists, they are esteemed real plants; for they have a regular root, a stalk consisting of several arrangements of fibres, the interstices of which are filled up with a parenchymatous substance, leading from the root to the head or umbel, the under-side of which is full of lamellæ or chives, every one of which is a regular pod or seed-vessel. If these lamellæ are examined in their several states, the seeds in them may be easily discovered, and are always found to be of a size and degree of maturity proportioned to the state

of the plant: they have each of them also a filiquaceous aperture lengthwise, the seeds lying in rows ready to fall through it. The plant is easily and regularly propagated through these, and may not only be raised from seed, but, like many other plants, may be propagated by roots; the several filaments at the root producing tubercles, in the manner of the potatoe; from each of which there will arise new roots, and a new plant. Hence, like other vegetables, they are annually propagated by the gardeners near London for sale. We shall therefore describe the method of cultivating them; but as there are several unwholesome sorts, we shall first give a short description of the true eatable kinds. These at first appear of a roundish form, like a button, the upper part of which, as also the stalk, is very white: but being opened, the under part is of a livid flesh-colour, but the fleshy part, when broken, is very white: when these are suffered to remain undisturbed, they will grow to a large size, and explicate themselves almost to a flatness, and the red part underneath will change to a dark colour.

Mr. Miller directs the following method of cultivating them. If you have no beds of your own that produce them, you should look abroad in rich pastures, during the months of August and September, till you find them; and then opening the ground about their roots, you will often find the earth full of small white knobs, which are off-sets from the mushrooms: these should be carefully gathered, and preserved dry with the earth about them. The mushroom-beds should be made of dung in which there is good store of litter. These beds should be made on dry ground, and the dung being laid upon the surface about a foot thick, two feet and a half broad, and of a length in proportion to the quantity of mushrooms desired, it should be covered about four inches deep with strong earth; upon this lay more dung, about ten inches thick; then another layer of earth; still drawing in the sides of the bed, so as to form it like the ridge of an house, which may be done by three layers of dung and as many of earth. When the bed is finished it should be covered with litter, to keep out the wet, and prevent its drying; in this situation it may remain eight or ten days, by which time it will be of a proper degree of warmth; the litter should then be taken off, the sides of the bed smoothed, and a covering of light rich earth should be laid over the bed; upon this the small roots or off-sets of the mushrooms should be put, placing them two or three inches asunder; then gently cover them about half an inch thick with the same light earth; and again put on the covering of litter. The great skill in managing these beds, is that of keeping them in a proper temperature of moisture. By this means mushrooms may be produced all the year; and when the beds are destroyed, the surface which contains the dust and roots of the mushrooms, should be laid

by in a dry place for a fresh supply, till the proper time of using it.

MUSIC, is one of the seven sciences, commonly called liberal, and comprehended also among the mathematical, as having for its object discrete quantity or number, but not considering it in the abstract like arithmetic, but in relation to time and sound, in order to make a delightful harmony: or it is the art of disposing and conducting sounds considered as acute and grave; and proportioning them among themselves, and separating them by just intervals pleasing to the sense.

Mr. Malcolm defines it a science that teaches how sound, under certain measures of time and tune, may be produced; and so ordered and disposed, as either in consonance (i. e. joint sounding) or succession, or both, they may raise agreeable sensations.

MUSK, a dry, light, and friable substance, of a dark blackish colour, tinged with purple; it is a kind of perfume of a very strong scent, and only agreeable when in a very small quantity, or moderated by the mixture of some other perfume. It is found in a kind of bag or tumour which grows under the belly of a wild beast called moschus. See MOSCHUS. Musk is brought to us sewed up in a kind of bladders or cases of skin of the bigness of a pigeon's egg, or larger, each containing from two or three drams to an ounce of musk. These are covered with a brownish hair, and are the real capsules in which the musk is lodged while on the animal. That which is unadulterated appears in masses, of loose and friable granules, which are soft to the touch, and easily crumble between the fingers, feeling somewhat smooth and unctuous.

Musk taken inwardly produces ease from pain, quiet sleep, and a copious diaphoresis: hence it has been found of great use in spasmodic disorders, petechial, malignant, putrid fevers, the jail distemper, hiccoughs, &c. and Dr. Wall observes, that it has been found useful in spasmodic disorders, given by way of clyster. The operation of musk in some respects resembles that of opium; but it does not leave behind it any stupor or languidness, which the other often does. Musk seems likely to answer in those low cases where sleep is much wanted, and opiates are improper. It is said to be best given in a bolus, in which form those who are most averse to perfumes, may take it without inconvenience. Fifteen grains or more are now given in a dose with great success.

MUSKET, a fire-arm borne on the shoulder, and used in war. The length of the musket is fixed at three feet eight inches from the muzzle to the pan, and it carries a ball of sixteen to the pound.

MUSKETOON, a kind of short thick musket, whose bore is the thirty-eighth part of its length: it carries five ounces of iron, or seven and a half of lead,

lead, with an equal quantity of powder. This is the shortest sort of blunderbusses. See the article **BLUNDERBUSS**.

**MUSLIN**, a fine thin sort of cotton-cloth, which bears a downy knap on its surface. There are several sorts of muslins brought from the East-Indies, and more particularly from Bengal; such as doreas, betelles, mulmuls, tanjees, &c.

**MUSTARD**, *Sinapis*, in botany. See the article **SINAPIS**.

**MUSTER**, in the marine, a summoning together the crew of any particular ship, and calling them severally over by their names.

**MUTE**, in grammar, a letter which yields no sound without the addition of a vowel.

**MUTILATION**, the retrenching or cutting away any member of the body.

This word is also extended to statues and buildings, where any part is wanting, or the projecture of any member, as a cornice or an impost, is broken off.

**MUTULE**, in architecture, a kind of square modillion set under the cornice of the Doric order. See **DORIC**.

The only difference between the mutule and modillion consists in this, that the former is used in speaking of the Doric order, and the latter in the Corinthian.

**MUZZLE of a Gun or Mortar**, the extremity at which the powder and ball is put in; and hence, the muzzle-ring is the metalline circle, or moulding, that surrounds the mouth of the piece.

**MYAGRUM**, in botany, a genus of plants, the corolla whereof consists of four plane, roundish, obtuse petals, disposed cross-wise, and narrower than the unguis. The fruit is a bivalve turbinatocordated small pod, lightly compressed and rigid, with the apex ending in a conical rigid style; the seeds are roundish.

**MYGINDA**, in botany, a genus of plants, whose flower contains four roundish, plane, spreading petals, with four subulated filaments topped with roundish antheræ. The fruit is a globose drupe, containing an acute oval nut.

**MYLOGLOSSUM**, in anatomy, is, according to Heister, no more than a part of the mylohyoides, though other anatomists make it a distinct pair of muscles, thus called because it arises about the back-side of the molares, and is inserted into the ligament of the tongue, helping to pull it upwards; being the same with what Cowper calls styloglossum.

**MYLOHYOIDÆUS**, in anatomy, one of the five pair of muscles belonging to the os hyoides. The mylohyoidæus arises with a large base from the bottom of the lower jaw, near the chin, and terminates at the base of the os hyoides. See the article **HYOIDES**.

Besides the common use ascribed to this muscle, which is to move the hyoides, the tongue, and the larynx, both upwards, inwards, and sideways, its series of transverse fibres have a farther use, when it is at rest; and that is, to compress the glands under the tongue, and by this means promote the discharge of the saliva into the mouth from the lower salivary ducts: whence it is we use this muscle, when we want saliva in the mouth.

**MYOLOGY**, *μυολογια*, that part of anatomy which treats of the muscles of the human body.

**MYOPIA**, or **MYOPIAS**, short-sightedness, a species of vision, wherein objects are seen distinctly only at small distances; which is incident to persons who have the cornea or crystalline, or either of them, too convex.

**MYOSOTIS**, in botany, a genus of plants whose flower is monopetalous and saucer-shaped; the limb is cut into five parts, and the edges are emarginated: in the bottom of the cup are placed four smooth, acuminate, oval seeds.

**MYRIAD**, a term sometimes used to denote ten thousand.

**MYRICA**, in botany, a genus of the dioecia class of plants; the male flowers are produced in an oblong oval amentum, imbricated on every side; the female flowers have no corolla; the pistillum is an oval germen, with two slender styles; the fruit is an unilocular berry, containing a single seed.

**MYRIOPHYLLUM**, in botany, a genus of plants, producing male and female flowers on the same plant; the male flower has no corolla; the cup is composed of four oblong erect leaves, and the stamina are eight hairy filaments, terminated with oblong antheræ; the female flower is like the male, and contains four oblong germina, which afterwards become four oblong seeds.

**MYRISTICA**, the nutmeg-tree, in botany. See **NUTMEG**.

**MYRMECIA**, or **FORMICA**, a painful kind of wart, with a broad base, and deeply rooted; growing on the palms of the hands, and soles of the feet.

**MYROBALANS**, a kind of medicinal fruit, brought from the Indies, of which there are five kinds: 1. the citrine, of a yellowish red, hard, oblong, and the size of an olive: 2. the black or Indian myrobalan, of the bigness of an acorn, wrinkled, and without a stone: 3. chebulic myrobalans, which are of the size of a date, pointed at the end, and of a yellowish brown: 4. emblic, which are round, rough, the size of a gall, and a dark brown: and, 5. belleric, which are hard, round, of the size of an ordinary prune, less angular than the rest, and yellow.

Each of these kinds are slightly purgative and astringent; but Quincy observes, that the best of them are not worth regarding, since they rather clog than assist any composition.

**MYRRH**,

## M Y R

**MYRRH**, a vegetable production of the gum or resin kind, issuing by incision, and sometimes spontaneously, from the trunk and larger branches of a tree growing in Egypt, Arabia, and Abissinia. The incisions are made twice a year, and the myrrh oozing out, is received on rush mats dispersed underneath.

Myrrh is sent over to us in loose granules of various sizes, from that of a pepper-corn to the bigness of a walnut. The generality of them, however, is from the size of a pea, to a little more than that of a horse-bean: these are sometimes roundish, but often irregularly long and contorted.

The colour of myrrh is a reddish brown, with more or less of an admixture of yellow, and in the purest pieces it is somewhat transparent. Its taste is bitter and acrid, with a peculiar aromatic flavour, but very nauseous: but its smell, though strong, is not disagreeable. It is to be chosen in clear pieces, light, friable, and of the bitterest taste.

Myrrh is of great use in medicine; it powerfully resolves and attenuates thick and viscid blood, concretion bile, and glutinous humours; it is good in obstructions of the menses, and in infarctions of the viscera. It also promotes delivery, and expulsion of the secundines; it is good in asthma, and in cases of tubercles of the lungs; it is of great service in the jaundice, and in cachectic complaints; it destroys worms, strengthens the stomach, and dissipates flatulencies.

Externally applied, it is discutient and vulnerary; it cleanses old ulcers, and disposes them to heal; but it gives many people the head-ach: and as it promotes discharge of blood, should never be given to persons subject to such discharges, as spitting of blood, or the like, or to women in the time of their pregnancy. It is administered either in pills, boluses, or tinctures; it not conveniently agreeing with any other forms.

**MYRSINE**, in botany, a genus of plants whose flower consists of a single petal, divided into five semi-oval, obtuse, and connivent petals: the fruit is a roundish depressed berry, containing five cells, with a single seed in each.

**MYRTIFORM**, in anatomy, an appellation given to several parts, from their resembling myrtle-berries: thus we meet with the myrtiform caruncles, and the myrtiform muscle of the nose, which arises near the incisivus of the upper lip, and is inserted into the alæ of the nose.

**MYRTLE**, *Myrtus*, in botany, a genus of plants, the flower of which consists of a monophyllous cup, in which is inserted five large oval petals, with a great number of hairy filaments topped with small antheræ: the fruit is an oval berry, with three cells, containing in each a kidney-shaped seed.

There are several sorts of myrtle, such as the broad-leaved myrtle, narrow-leaved myrtle, nutmeg myrtle, orange myrtle, variegated myrtle, with

## M Y T

several other varieties. They may be all propagated from cuttings, or slips, in the summer; making choice of the most vigorous shoots of the same year's growth: they should be planted in pots and covered with glasses, which prevents the air from getting at them, and facilitates their taking root. When winter comes on, they should be removed into a green-house; and the spring following, they may be transplanted singly into small pots. In hot weather they should have plenty of water.

Myrtle-berries are rough and astringent, not much prescribed in composition for inward use, but they enter several strengthening plaisters; the syrup of them is esteemed good against abortion, and in fluxes of all kinds.

**MYRTUS**, the myrtle. See **MYRTLE**.

**MYSTERY**, something secret or concealed, impossible or difficult to comprehend.

**MYSTICAL**, something mysterious or allegorical.

Some of the commentators upon the sacred writings, besides a literal, find also a mystical meaning. The sense of scripture, say they, is either that immediately signified by the words and expressions in the common use of language; or it is mediate, sublime, typical, and mystical. The literal sense they again divide into proper literal, which is contained in the words taken simply and properly; and metaphorical literal, where the words are to be taken in a figurative and metaphorical sense. The mystical sense of scripture they divide into three kinds: the first, corresponding to faith, and called allegorical; the second, to hope, called anagogical; and the third, to charity, called the tropological sense: and sometimes, they take the same word in scripture in all the four senses; thus the word Jerusalem, literally signifies the capital of Judæa; allegorically, the church militant; tropologically, a believer; and anagogically, heaven. So that passage in Genesis, *let there be light, and there was light*, literally signifies corporeal light; by an allegory, the Messiah; in the tropological sense, grace; and anagogically, beatitude, or the light of glory. See the articles **ANAGOGICAL**, &c.

**MYSTICS**, a religious sect, distinguished by their professing a pure, sublime, and perfect devotion, with an intire disinterested love of God, free from all selfish considerations, and by their aspiring to a state of passive contemplation.

**MYTHOLOGY**, *μυθολογια*, the history of the fabulous gods and heroes of antiquity, with the explanations of the mysteries and allegories couched therein.

Lord Bacon thinks, that a great deal of concealed instruction and allegory was originally intended in most part of the ancient mythology: he observes, that some fables discover a great and evident similitude, relation, and connection, with the thing they signify; as well in the structure of the fable, as in

## N A D

the meaning of the names, whereby the persons or actors are characterized.

The same writer thinks, it may pass for a farther indication of a concealed and secret meaning, that some of these fables are so absurd and idle in their narration, as to shew an allegory even afar off: but the argument of most weight upon this subject he takes to be this, that many of these fables appear by no means to have been invented by the persons who relate them: he looks on them not as the product of

## N A I

the age, nor invention of the poets, but as sacred relics (as he terms them) gentle whispers, and the breath of better times, that from the tradition of more ancient nations, came at length into the flutes and trumpets of the Greeks. He concludes, that the knowledge of the early ages was either great or happy: great, if they by design made this use of trope and figure; or happy, if, whilst they had other views, they afforded matter and occasion to such noble contemplations.

## N.

**N**, The thirteenth letter, and tenth consonant of our alphabet: it is a liquid, the sound of which is formed by forcing the voice strongly through the mouth and nostrils; being at the same time intercepted by applying the tip of the tongue to the fore-part of the palate, with the lips open. It suffers no consonant immediately after it, in the beginning of words and syllables; nor any before it, except *g*, *k*, and *s*; as in *gnaw*, *know*, *snow*, &c.

As a numeral, *N* stands for 900; and with a dash over it, thus *N̄*, for 900,000.

*N.* or *N<sup>o</sup>.* stands for *numero*, i. e. in number; and *N. B.* for *nota bene*, note well, or observe well.

Among the ancient Romans, *N.* denotes *Nepos*, *Nonnius*, &c. *N. C.* *Nero Cæsar*, or *Nero Claudius*; *N. L.* *Non Liquet*; *N. P.* *Notarius Publicus*; and *N. B. L.* stands for *nobilis*.

*NADIR*, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads.

The zenith and nadir are the two poles of the horizon. See *HORIZON* and *POLE*.

*Sun's NADIR*, in astronomy, is the axis of the cone formed by the earth's shadow: it is thus called, because being produced, it gives a point in the ecliptic diametrically opposite to the sun.

*NAHUM*, or *the Prophecy of NAHUM*, a canonical book of the Old-Testament.

*Nahum*, the seventh of the twelve lesser prophets, was a native of *Elkoshai*, a little village of *Gallilee*. The subject of his prophecy is the destruction of *Nineveh*, which he describes in the most lively and pathetic manner; his style is bold and figurative, and can hardly be exceeded by the most perfect masters of oratory. This prophecy was verified at the siege of that city by *Astyages*, in the year of the world 3378, 622 years before Christ.

The time of *Nahum's* death is unknown: the Greek menologies, and the Latin martyrologies, place his festival on the first of December.

*NAIADS*, in mythology, the nymphs of the fountains. See *NYMPH*.

*NAJAS*, in botany, a genus of plants, the male corolla of which is monopetalous, and divided into four segments at the limb: the female one has no flower-petals: the fruit is an oval capsule, containing ovato-oblong seeds.

*NAIL*, *Unguis*, in anatomy, a kind of bony excrescence, growing on the fingers and toes of men, and several other animals.

The number, figure, size, and colour of the nails, need no explanation. The several parts of the

## N A P

the nails have their several names: the extremity is called the apex; the opposite part of this is the root or base; near which there is a white part, called the lunula, from its figure somewhat resembling a segment of a circle.

As to the substance of the nails, they are composed of the cutaneous papillæ, elongated and indurated, and firmly connected to one another in a longitudinal direction; for this reason, they are very sensible at the roots, where these papillæ are yet tender; but at the apex, where they are perfectly indurated, they may be cut without pain.

The papillæ, of which the nails are formed, arise out of the skin, not only at the root of the nail, but all over the greater part of its under surface. It is by this means, that the nails are so firmly connected to the skin; and it is owing to the continual accession of more and more papillæ, as they approach towards the apex, that they become harder and firmer in that part. They may easily be separated intire, from dead subjects, by hot water.

NAILS, in building, &c. small spikes of iron, brass, &c. which being drove into wood, serve to bind several pieces together, or to fasten something upon them.

NAIL, is also a measure of length, containing the sixteenth part of a yard.

NAKED, in architecture, is the surface or plane from whence the projectures arise, or which serves as a ground to the projectures. Thus we say, the foliage of a capital ought to answer to the naked of a column, and that a pilaster ought to exceed the naked of the wall by so many inches.

NAKED FIRE, in chemistry, is an open fire, or one where a vessel is immediately exposed to the fire.

NAKED SEEDS, in botany, are those that are not inclosed in any pod or case.

NAMA, in botany, a genus of plants whose flower consists of a pentaphyllous cup, and five ovate patent petals: the fruit is an oval bivalvular capsule, having one cell, which contains a great number of very small seeds.

NAMUR-MARBLE, a name given by our artificers to a species of black marble, which is very hard, and capable of a good polish, but has no variegations of any other colour.

It is common in Italy, France, and Germany, and is the species called the lucullean marble by the Romans.

NAPE, a name used for the hind part of the neck, supposed to be on account of the short hair growing there, in resemblance of the nap of a cloth.

NAPHTHA, in natural history, a fluid mineral body, of a thin consistence, bright and pellucid, of a strong smell, very readily inflammable, and when pure, burning away without leaving any residuum.

NAPLES-YELLOW, the common name in the colour-shops of London, and among our painters, for the ochre called Giallino.

## N A R

NARCISSUS, the daffodil, in botany, a genus of bulbous-rooted plants, the flower of which comes out of an oblong, obtuse, compressed spatha, which opens on the side, and withers: the corolla consists of a nectarium, formed of one leaf, of a cylindric or funnel shape, coloured at the top, and curled or plicated at the brim; and of six oval, acuminate, plane petals, affixed externally to the tube of the nectarium, above its base: the stamina are six subulated filaments, joined to the nectarium, but shorter; these are topped with oblong antheræ: the fruit is a roundish capsule, obtusely trigonal, having three cells, which are filled with globose seeds.

There are various sorts of the narcissus; some of which are much admired for their sweet scent. The roots are planted in autumn, and are frequently blown in glasses with water, in rooms, during the spring.

The root of the common daffodil is emetic, vulnerary, and detergent.

NARCOTICS, in medicine, soporiferous medicines, which excite a stupefaction.

Narcotics, called also hypnotics, anodynes, or stupefactive, are said by Hoffman, to be such kind of remedies as, by their subtle, noxious, and deleterious exhalations, diminish or quite destroy the sense and motion of the solid parts. Among narcotics the most eminent are those which are usually prepared for medicinal uses of the whole poppy, especially opium; as also all those prepared of mandragoras, hyoscyamus, stramonium, and datura. These, says the abovementioned author, are not without reason reckoned poisons, since they exert their noxious influence in a short space of time, when taken in a small quantity; and a quantity a little larger than ordinary proves mortal. Besides, their principal operation is on the most noble parts of the body, which are the organs of sense and motion; and moreover, they act by means of an element quite opposite to nature, a noisome sulphureous vapour, by which they diminish to a considerable degree, or quite destroy the sense and motion of the motive fibres. The elements by which narcotics act, are of an highly volatile and penetrating nature, since they deeply insinuate themselves like a vapour into the pores of the membranes and nerves, and by contaminating that most pure and moveable fluid, deprive by little and little, the solids of their tone and motion.

Narcotics act on the nervous membranes of the stomach and intestines, principally by means of a vaporous and fetid sulphur; for as the stomach and intestines first and immediately feel the force and efficacy of remedies, they are so much the more liable to suffer from the influence of medicines which are of a stronger and more penetrating nature than ordinary. These medicines have also a mighty influence on the membranes of the brain, where, by greatly diminishing the spring and systole of the arteries

arteries, they cause stagnation of their blood therein, with distensions of the vessels of the head, by which means they induce a torpor, drowiness, deliriousness, with frightful and troublesome dreams. These medicines were therefore suspected, by the wisest physicians among the antients, in the cure of diseases, on account of their deleterious quality.

**NARDUS**, **SPIKENARD**, in botany, a genus of plants, the corolla whereof is formed of two valves; the exterior is long and of a lanceolate-linear figure; it terminates in an arista or awn, and contains within it the other, which is smaller, and terminates in a shorter awn: the seed is single, of a linear oblong figure, narrower at top than at bottom, and pointed at each end; the corolla surrounds it by way of a pericarpium.

This plant is cephalic and stomachic; it is recommended in nephritic cases, and as a promoter of the menses. It is also given in chronic cases to remove obstructions of the viscera: however, the modern practice does not use it much, except as an ingredient in some of the official compositions. It has a very fragrant aromatic smell and taste.

**NARRATION**, in oratory and history, a recital or rehearsal of a fact as it happened, or when it is supposed to have happened.

Narration is of two kinds, either simple or historical, as where the auditor or reader is supposed to hear or read of a transaction at second hand; or artificial and fabulous, as where their imaginations are raised, and the action is as it were re-acted before them. The narration, according to the writers of rhetoric, makes the second part of a just speech or harangue, *viz.* that immediately following to the exordium. It makes the whole history, abating for the occasional reflections, episodes and digressions. Cicero requires four virtues in a narration, *viz.* perspicuity, probability brevity and sweetness. The narration is rendered perspicuous by observing the order of time, by using none but proper and known terms, and by reciting the action uninterruptedly. It is rendered probable by the credibility of the narrator, by the simplicity and openness of the narration, by avoiding every thing far remote from the common sense and opinion of mankind, and by a precise detail of circumstances. It is rendered brief by taking it up no higher than is necessary, nor fetching it back; and by avoiding trivial circumstances. Lastly it is rendered sweet by using smooth numerous, and well sounding words; by arranging them so as to avoid any hiatus or clashing; by the greatness, the novelty, and unexpectedness of the things related; and by enriching it with tropes and figures.

**NARRATION**, in poetry, is used for the action, or event, that make the subject of an epic poem.

**NARWAL**, in ichthyology, the unicorn fish, so called from a long wreathed tooth, ten or more feet in length, which has more the appearance of a

horn than a tooth; though it be really a tooth fixed in the gomphosis of the upper jaw, altogether in the manner of other teeth: hence some have called it monodon, which is certainly a more proper name than that of the unicorn fish.

The narwal is a fish of the whale kind, often growing to twenty-five feet in length, but is more commonly found from sixteen to twenty.

**NASIAS**, in anatomy, a thin bone making the upper part of the nose. See the article **Nose**.

**NATES**, in anatomy, a term expressing those two fleshy exterior parts of the body, vulgarly called the buttocks.

**NATES CEREBRI**, two circular protuberances of the brain, situated on the back side of the medulla oblongata, near the cerebellum.

**NATION**, a collective term, used for a considerable people inhabiting a certain extent of land, confined within fixed limits, and under the same government.

**NATIVE**, a person considered as born in a certain place which was the proper residence of his parents, and where he received his education.

**NATIVE**, or **NATIVUS**, in our ancient law-books, signifies a person born in the state of villainage, in contradistinction to a bonds-man, or one who became a villain by his own act and deed.

**NATIVITY**, or **NATAL-DAY**, the day of a person's birth. The word nativity is chiefly used in speaking of the saints, as the nativity of St. John the Baptist, &c. But when we say the Nativity, it is understood of that of Jesus Christ, or the feast of Christmas, See the article **CHRISTMAS**.

**NATIVITY**, in old law-books, signifies villainage or servitude.

**NATIVITY**, in astrology, the situation of the heavens, and particularly of the twelve houses at the moment of a person's birth.

**NATRUM**, the nitre of the antients, in natural-history, is a genuine, pure and native salt, extremely different from our nitre, and indeed from all the other native salts; it being a fixt alkali, plainly of the nature of those made by fire from vegetables, yet capable of a regular crystallization, which those salts are not. It is found on the surface of the earth, or at very small depths within it, and is naturally formed into thin and flat cakes or crusts, which are of a spongy or cavernous substance, very light and friable, and when pure, of a pale brownish white; but as its spongy texture renders it very subject to be fouled by earth received into its pores, it is often met with of a deep dirty-brown, and not unfrequently reddish.

**NATURAL**, in general, something that relates to nature.

Natural-children are those born out of lawful wedlock.

The natural functions, are those actions whereby the aliments are changed and assimilated so as to become a part of the body.

**NATURAL HISTORY**, a description of the productions of the earth, air, water, &c.

**NATURAL INCLINATIONS**, are the tendencies of our minds toward things seemingly good. See the articles **GOOD** and **PASSIONS**.

**NATURAL PHILOSOPHY**, that which considers the powers and properties of natural bodies, and their mutual actions on one another.

The business of natural philosophers, says Boerhaave, is to communicate a solid and accurate knowledge of all the bodies in being, and all the affections thereof. Nor can this science be acquired otherwise than by observing, by means of our senses, all the objects which the author of nature has made cognizeable thereto: hence the first and principal part of this science is to collect all the manifest and sensible appearances of things, and reduce them into a body of natural history. Now there are two ways of making such observations; the first when we view things nearly as they happen to turn up, without any design or intervention of our own; in which way no great improvements can be expected in the art, because chance having here the direction, only exhibits occasional or extemporary properties: the other method is, when, after a thorough acquaintance with bodies, we apply them to other bodies equally known, diligently attending to the result, and observing whether any thing new arises. See the article **EXPERIMENTAL PHILOSOPHY**.

**NATURAL**, in music, is a term variously used: thus natural music is the same with vocal, in opposition to artificial music, or that performed on instruments, A song is also called natural, when its notes move easily and gracefully, the voice or instrument being no wise forced or strained. Natural harmony is that produced by the natural and essential chord of the mode.

A natural note is used to contradict those flats and sharps that are used at the beginning of a stave; and in such case, it must be taken exactly as in the gamut.

**NATURAL**, in heraldry, is when animals, fruits, flowers, &c. are blazoned with their natural colours.

**NATURALIST**, a person well versed in the study of nature, and the knowledge of natural bodies, especially in what relates to animals, vegetables, metals, minerals, and stones. See the article **NATURAL PHILOSOPHY**.

**NATURALIZATION**, in law, the act of naturalizing an alien, or placing him in the condition of a natural born subject. In England, this is done by act of parliament; but none can be naturalized before they have received the sacrament of the church, and taken the oaths of allegiance and supremacy. A person who is naturalized may

have lands by descent, as heirs at law, as well as obtain them by purchase: but they are disabled from being of the king's privy council, or of holding offices, 7 Jac. I. 12 W. III. c. 2. By a late statute it is ordained, that all children born out of the king's dominions, whose fathers were or are natural subjects to this kingdom at the time of their birth, shall be adjudged natural-born subjects of this realm, except children of parents who are attainted of treason, or that are in the actual service of a foreign prince at enmity with us. 4 Geo. II. c. 2. By an act of 13 Geo. II. all Jews who have resided in the British colonies in America, without being absent two months at any one time, are declared naturalized without their receiving the sacrament of the Lord's supper.

**NATURALS**, *res naturales*, among physicians, whatever naturally belongs to an animal, in opposition to non-naturals. See the article **NON-NATURALS**.

**NATURE**, *Natura*, according to Mr. Boyle, has eight different significations; it being used, 1. For the author of nature, whom the schoolmen call *Natura Naturans*, being the same with God. 2. By the nature of a thing, we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature, with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we say, that a stone by nature falls to the earth. 5. Sometimes we understand, by nature, the established course of things. 6. Sometimes we take nature for an aggregate of powers belonging to a body, especially a living one; in which sense physicians say, that nature is strong, weak, or spent; or that, in such and such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phoenix, or chimera, that there is no such thing in nature. 8. Sometimes too, and that most commonly, we express by the word nature a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature, less ambiguous than those already mentioned, and with regard to which many axioms, relating to that word, may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world, in its present state, considered as a principle; by virtue whereof they act and suffer, according to the laws of motion, prescribed by the author of all things. And this makes way for the other subordinate notion;

since the particular nature of an individual consists in the general nature, applied to a distinct portion of the universe; or, which is the same thing, it is a particular assemblage of the mechanical properties of matter, as figure, motion, &c.

NAVAL, relating to a ship, whence

NAVAL ARMAMENT, the same with fleet of ships of war, which see.

NAVAL CAMP, in antiquity, a fortification, consisting of a ditch and parapet on the land side, or a wall built in the form of a semi-circle, and extended from one point of the sea to another. This was sometimes defended with towers, and beautified with gates, through which they issued forth to attack their enemies. Homer hath left us a remarkable description of the Grecian fortifications of this sort in the Trojan war, of which we shall present our readers with Mr. Pope's translation.

Then to secure the camp and naval pow'rs,  
They rais'd embattled walls with lofty tow'rs;  
From space to space were ample gates around,  
For passing chariots, and a trench profound  
Of large extent; and deep in earth below,  
Strong piles infix'd stood adverse to the foe.

Towards the sea, or within it, they fixed great piles of wood, like those in their artificial harbours; before these the vessels of burthen were placed, in such order, as that they might be instead of a wall, and give protection to those within: in which manner Nicias is reported by Thucydides to have encamped himself. But this seems only to have been practised when the enemy was thought superior in strength, and raised great apprehensions of danger in them.

When their fortifications were thought strong enough to defend them from the assaults of enemies, it was frequent to drag their ships to shore, which the Greeks called *εναλκνειν*, the Romans *subducere*. Around the ships the soldiers disposed their tents; as appears every where in Homer: but this seems only to have been practised in winter, when their enemies fleet was laid up, or could not assault them, or in long sieges, and when they lay in no danger from their enemies by sea, as in the Trojan war, where the defenders of Troy never once attempted to encounter the Grecians in a sea-fight.

The adjacent places were usually filled with inns and stews, well stocked with females, that prostituted themselves to the mariners, merchants, and artificers of all sorts, who flocked thither in great numbers; this, however, appears to be only in times of peace.—*Potter's Antiquities of Greece*.

NAVE, in architecture, the body of a church, where the people are disposed, reaching from the balluster, or rail of the choir, to the chief door.

Some derive the word nave from *ναος*, a temple; and others from *ναυς*, a ship, by reason the vault or roof of a church bears some resemblance to a ship.

NAVEL, *Umbilicus*, in anatomy, the center of the lower part of the abdomen; being that part where the umbilical vessels passed out of the foetus to the placenta of the mother.

The navel-string, or funiculus umbilicalis, of the foetus, besides its vein and two arteries, is composed of a spongy substance, in which these vessels are lodged, which upon entering the placenta, are divided into numerous branches, and lesser ramifications.

As soon as the infant and after-burden are delivered, a firm ligature is made upon the navel-string, with a strong thread folded several times together, and about two or three fingers-breadth from the abdomen: this done, the navel-string leading to the placenta is to be cut off, and the wound dressed with lint, till the part on which the ligature was made, becoming dry, falls off of itself.

NAVEL-WORT, *Cotyledon*, in botany. See the article COTYLEDON.

NAVEW, in botany. See the article RAPE-SEED.

NAVICULARE Os, in anatomy, a bone of the foot, lying between the astragalus and ossa cuneiformia, and so called from its resemblance to a boat.

It has a glenoid cavity, for its articulation with the head of the astragalus; and its anterior faces are received into the sinuses of the ossa cuneiformia.

NAVIGATION, the art of conducting or carrying a ship from one port to another. See the article SHIP.

Navigation implies not only the mechanical art of managing the sails, and working a ship; that is, of causing it to observe such motions and directions, as are assigned by the navigator; which must be learned on ship-board, and in the practice of sailing; but likewise the theory thereof, which depends on the navigator's being before-hand furnished with the following elements.

1. A table of the latitudes and longitudes of the most remarkable parts of the sea-coasts, islands, rocks, shoals, &c. in the frequented parts of the world.

2. Maps and charts of the seas and lands, together with the depths of water, and the times and setting of the tides upon the coast he may have occasion to approach near.

3. The use and application of several instruments, necessary to point out the way a ship is to steer, to measure the rate she runs at, and to find the place she is in at any time.

4. A sufficient stock of mathematical learning, to enable him to make a right use of the observations that may be deduced from the preceding elements; but particularly trigonometry. See the article TRIGONOMETRY.

NAVIS, *Argo Navis*, or the ship Argo, in astronomy. See the article ARGO.

NAUMACHIA, in antiquity, a shew or spectacle

table among the ancient Romans, representing a sea-fight.

**NAUSEA**, in medicine, a reaching, or propensity and endeavour to vomit, arising from a loathing of food, excited by some viscous humour that irritates the stomach.

In this disorder the patient is so far from desiring aliment, that he rather loaths it. It either proceeds from a fault in the stomach, or else is derived from other diseases, or is a symptom thereof, particularly acute inflammations, asthma, dropsy, hypochondriac passion, &c. or when the humours are corrupted, and the spirits suppressed, in malignant diseases. Vomiting in this case is proper, or purging when that is forbid. To these should be joined strengtheners of the stomach, and chiefly stomachic balsams, made of oil of nutmegs, and distilled oils, and stomachic plasters. Hoffman says, that there is nothing better than mint, its spirituous water, and distilled oil; likewise mastic and its spirit, or balsam of Peru distilled with salt of tartar. In acute fevers, especially the malignant, epidemic, and spotted, there is generally a nausea and reaching to vomit, for which reason emetics are good: likewise in the dysentery, especially when it is epidemic in a camp, emetics are not only useful, but necessary, with a slender diet.

**NAUTICAL PLANISPHERE**, a description of the terrestrial globe upon a plane for the use of mariners, more usually called chart. See the article **CHART**.

**NAUTICAL COMPASS**, the same with mariners compass. See **COMPASS**.

**NAUTICUS**, in anatomy, is the name of a muscle, called also tibialis posticus. See the article **TIBIALIS**.

**NAUTILUS**, in natural history, a simple shell, having no hinge, formed of one continued piece, rolled as it were into a spiral form, and having its cavity divided into a great number of cells by transverse partitions, each of which has a perforation, and is continuous to the others, by means of a siphunculus carried the whole length of the shell. The animal inhabiting this shell is a sepia.

Of the nautili, some are thick and strong; others thin, light, and brittle; some are aurated, others are not so; and some are smooth on the external surface, and others furrowed.

**NAVY**, the fleet or shipping of a prince or state. See **FLEET**.

**NAZAREANS**, in church history, a name originally given to all Christians in general, on account that Jesus Christ was of the city of Nazareth; but afterwards restrained to a sect of heretics, whose religion consisted of a strange jumble of Judaism and Christianity; observing at the same time the Mosaic law, and the several rites of the Christian religion.

**NAZARITES**, among the Jews, persons who, either of themselves or by their parents, were dedicated to the observation of Nazariteship.

They were of two sorts; namely, such as were bound to this observance for only a short time, as a week or month; or those who were bound to it all their lives. All that we find peculiar in the latter's way of life, is, that they were to abstain from wine, and all intoxicating liquors, and never to shave or cut off the hairs of their heads. The first sort of Nazarites were moreover to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afresh. Women as well as men might bind themselves to this vow.

**NEALED**, among sea-men, is used when the sounding is deep water close to the shore; as also when the shore is sandy, clayey, oozy, or foul and rocky ground.

**NEALING**, or rather **ANNEALING**. See **ANNEALING**.

**NEAP TIDES**. See **TIDES**.

**NEAPED**. When a ship wants water so that she cannot get out of the harbour, off the ground, or out of the dock, the sea-men say, she is neaped, or beneaped.

**NEAR**, or **NO NEAR**, at sea, a word of command from him that cons the ship to the man at the helm, requiring him to let her fall to the leeward.

**NEAT**, or **NET WEIGHT**, the weight of a commodity alone, clear of the cask, bag, case, or even filth.

**NEBEL**, in the Jewish antiquity, the same with the psaltery. See **PSALTERY**.

**NEBULOUS**, cloudy, in astronomy, a term applied to certain of the fixed stars, which shew a dim hazy light; being less than those of the sixth magnitude, and therefore scarce visible to the naked eye.

**NEBULY**, or **NEBULEE**, in heraldry, is when a coat is charged with several little figures, in form of words, running within one another; or when the outline of a bordure, ordinary, &c. is indented or waved.

**NECESSARY**, in a philosophical sense, that which cannot but be, or cannot be otherwise. See the next article.

**NECESSITY**, whatever is done by a necessary cause, or a power that is irresistible, in which sense it stands opposed to freedom. See the article **FREEDOM**.

The schools distinguish a physical necessity, and a moral necessity; and a simply absolute necessity, and a relative one. Physical necessity, is the want of a principle, or of a natural means necessary to act, which is otherwise called a physical or natural impotence. Moral necessity, is only a great difficulty,

culty, such as that arising from a long habit, a strong inclination, or violent passion. Simple or absolute necessity, is that which has no dependence on any state or conjuncture, or any particular situation of things; but is found every where, and in all the circumstances in which the agent can be supposed; such as in a blind man, the necessity he is under of not distinguishing colours. Relative necessity, is that which places a man in a real incapacity of acting or not acting in those circumstances, and that situation he is found in, though in other circumstances, and in another state of things, he might act or not act; such, in the opinion of the Janfenists, is the necessity of doing evil, in a man, who, with a violent passion, has only a feeble grace to resist it; or the necessity of doing well, in a man, who, having grace of seven or eight degrees of strength, has only concupiscence of two or three degrees to withstand. All these kinds of necessity are opposite to freedom, or liberty; since even in the last, it is as impossible for a man to act or not act, as if he were in a state of absolute and physical necessity.

The schoolmen admit of other species of necessity, antecedent, concomitant, consequent, &c. Antecedent necessity, is that arising from an antecedent cause necessarily operating; such is the necessity of the sun's rising to-morrow morning. Concomitant necessity, arises from the antecedent and necessary cause, but depends upon the circumstances of the effect; the effect all the while being free: thus, it is necessary Peter sit, supposing he is sitting.

NECK, *Collum*, in anatomy, is that slender part situated between the head and the trunk of the body.

The neck consists of the following parts: 1. the common integuments: 2. seven vertebrae: 3. a number of muscles, which serve to move the head, the neck, the larynx, the pharynx, and the os hyoides: 4. a number of very large arteries, as the carotids, internal and external, and the vertebral ones: 5. of large veins, as the jugular, internal and external, and the vertebral ones: 6. of large nerves, of the par vagum, the intercostals, the recurrent, the diaphragmatics, and the vertebral: 7. a part of the spinal marrow: 8. the aspera arteria, or trachea, particularly the larynx, in which is an eminence called the pomum adami: 9. the pharynx, with a part of the oesophagus: 10. the thyroide, with some other smaller glands. See LARYNX, PHARYNX, JUGULAR, &c.

*Wounds of the NECK.* The treatment of these wounds ought to be different, according to the different nature of the wound. When the common integuments and muscular flesh only are wounded, it will require to be treated in the same manner as other slight wounds. See the article WOUND.

When the external jugular is wounded, the methods used after bleeding in that vein will be suffi-

cient. When the internal jugular vein is wounded, the hæmorrhage will be easily stopped by filling the wound with dry lint, or with the puff-ball or dusty-mushroom; laying over these applications square bolsters, and securing all with a bandage, drawn as tight as the situation of the place will admit. Where this method has no effect, the surgeon should make a proper pressure on the wounded part with his finger, till the hæmorrhage is intirely stopped; the dressings applied are not to be removed for three days, and then a vulnerary balsam and plaster is to be applied to heal the wound. In large wounds, or an intire division of the internal jugular, the surgeon, if present, should make a firm pressure with his finger on the wounded part, and make incisions lengthwise above the wound, till he can get at the vessel, and then make a firm ligature upon it, by the assistance of the crooked needle.

In case of a wound in the carotid artery, a surgeon, if present in time, should use the same method as in those of the internal jugular vein. This method is more likely to be attended with success in wounds of the upper and middle part of the vessel, than in those of the lower part of it; and where the wound is not in the trunk of the artery, but in one of its branches near the head, you should fill up the wound with lint dipt in some styptic liquor, and then cover it up with thick compresses, securing all with a tight bandage, and ordering an assistant to make a pressure upon the part with his hand, for some time after: and in these cases, the dressings are not to be removed till the third or fourth day.

In curing the wounds of the aspera arteria, the surgeon ought to clean the wound, and then endeavour to unite the parts by the help of sticking plasters; or where the wound is large, by making two stitches with a crooked needle, dressing the wounds afterwards in the usual manner, and enjoining the patient to keep his head in a proper situation. The wound thus treated, will easily heal, if it has been made either by puncture, or a cutting instrument; but if it has been made by a bullet, and any part of the aspera arteria is carried away, the future is to no purpose: wounds of this kind are only to be dressed with the vulnerary balsams. If the aspera arteria is intirely divided, and the lower end of it has shrunk into the cavity of the thorax, so that it cannot be laid hold on and united to the upper part, there can be no remedy.

When the oesophagus is wounded, what is taken in at the mouth comes out through the wound, and the patient is usually affected with hiccoughs and vomiting. When it is entirely divided, there is no remedy; but when it is only perforated, or wounded in part, the cure may be attempted, by dressing it with vulnerary balsams, endeavouring to unite it by means of sticking plasters, and enjoining the patient a strict abstinence for some days, giving nourishing clysters of broth or milk; but when the

necessities of nature require nourishment to be taken by the mouth, the wound should always be carefully cleaned afterwards, and dressed daily till it heals.

Wounds of the medulla spinalis, are best dressed with balsam of Peru, or medicines of the like nature, mixed with a small quantity of honey of roses, spread upon pledgits, and applied moderately warm. Slight ones of this kind, are sometimes healed by this means, but large ones in this part bring on certain death.

*Luxation of the NECK.* If life remain after such an accident, the patient is to be immediately laid flat on the ground or floor; then the surgeon laying hold of his head, is to extend it strongly, gently moving it from side to side, till he finds that the neck is restored to its natural posture.

Mr. Petit mentions another method, by means of flings: but Heister gives the preference to the former method, both as being more simple, and because the patient can be relieved much sooner.

*Wry NECK*, a deformity usually brought into the world with people; but sometimes it is occasioned by accidents afterwards.

When it is from birth, there is very little reason to imagine it curable, because the vertebrae of the neck are rendered crooked by that posture, while the bones are in a soft and pliable state.

There are, however, in the writings of surgeons, some instances of this disorder, even in these circumstances; being cured after twelve, sixteen, or eighteen years.

When this disorder comes on adults, it is occasioned generally by a contraction of the skin from a burn on one side, or from a strong spasmodic contraction of one of the mastoide muscles; which will at length become shorter and indurated, by continuing in that posture; or it may proceed from a relaxation of one or more of these muscles; in consequence of which, the neck will be contracted by the stronger antagonist-muscle on the opposite side; or, lastly, it may proceed from a preternatural ligament drawing down the head. And when either of these is the occasion of the disorder, there is hopes of a cure; especially if the patient be young, and the disorder not of long standing.

If this disorder be recent, and caused by a defluxion of humours, evacuating medicines, with mild sudorifics, and heat, may be of service. But when it arises from a contraction of the skin or muscles by burning, the repeated use of oils, ointments, and fomentations, may relax so far as to make a cure. A proper firm bandage must be applied to pull the head toward the natural posture, and a steel collar may be contrived, by which the patient will be suspended very frequently till the neck recover its proper position. But when all these fail, the manual assistance of the surgeon is to be called in.

If the skin is contracted by a burn, it must be carefully incised transversely in several places, and the incisions dressed so as to keep them open and dilated, and the head pulled to its proper position by a bandage, till the new flesh filling up these incisions, gives room for the head to stand even.

But if the wry-neck proceeds from a contraction of one of the mastoide muscles, or from some ligament, they are to be divided by a transverse incision in their lower part, near the clavicle or sternum.

*NECROMANCY*, a species of divination, performed by raising the dead, and extorting answers from them.

*NECROSIS*, in medicine, a term sometimes used for a mortification, or sphacelus.

*NECTAR*, *νεκτορ*, among ancient poets, the drink of the fabulous deities of the heathens, in contradistinction from their solid food, which was called ambrosia. See *AMBROSIA*.

This word is also used by some of the ancients to express honey.

*NECTARINE*, a well-known fruit, only differing from the peach by having a smoother rind and a firmer pulp.

For the management of nectarine-trees, and their generical characters, see the article *PEACH*.

*NECTARIUM*, among botanists, expresses what is sometimes only a part of the corolla, and sometimes, though more rarely, the whole: it is a part destined for the reception of the honey-juice of the plant, and is very various in its figure; being sometimes only a hollow in a petal, sometimes a little squama or tubercle, and sometimes only a plain tube.

*NEEDLE*, *Acus*, a very common little instrument or utensil, made of steel, pointed at one end, and pierced at the other; used in sewing, embroidery, tapestry, &c.

Needles make a very considerable article in commerce, though there is scarce any commodity cheaper, the consumption of them being almost incredible. The sizes are from No. 1. the largest, to No. 25. the smallest.

*Chirurgion's NEEDLE.* There are many cases wherein the use of the needle is highly necessary; in some of which, a cure cannot be completed without it, as in wounds of the belly, and in divided tendons.

In amputations they are found much preferable to the actual cautery; and in the operation of the aneurism, bubonocoele, lithotomy, &c. they very much forward the cure; and in a cataract and hare-lip, the cure is wholly performed by them.

For a description of the different needles used in the cure of each of these two last disorders, see the articles *COUCHING* and *HARE-LIP*.

Chirurgical needles are of different figures and sizes; being straight, crooked, and flat; and all of them

them very sharp, and mostly made of well-tempered metal. Those needles used for setons, and generally for the future of tendons, and for the sewing up of dead bodies, must be straight. In amputation, and all other sort of wounds, the crooked sort are used.

Mr. Monro, in the Medical Essays, observes, that needles of silver pierce more easily in stitching arteries, after amputation, than those made of steel.

*Magnetical NEEDLE*, in navigation, a long slender bar of steel, supported upon a small pivot, or center; on which, playing at liberty, it directs itself to certain points in or under the horizon; whence the magnetical needle is of two kinds, viz. horizontal, and inclinatory. See the article MAGNET.

Horizontal needles are those equally balanced on each side the pivot that sustains them; and which, playing horizontally with their two extremes, point out the north and south points of the horizon. For their application and use, see the article COMPASS.

In the construction of the horizontal needle, a piece of pure steel is provided, of a length not exceeding six inches, lest its weight impede its volubility, very thin, to take its verticity the better, and not pierced with any holes, or the like, for ornament sake, which prevent the equable diffusion of the magnetic virtue. A perforation is then made in the middle of its length, and a brass cap or head soldered on, whose inner cavity is conical, so as to play freely on a style or pivot headed with a fine steel point. The north point of the needle in our hemisphere, is made a little lighter than the southern; the touch always destroying the balance, if well adjusted before; and rendering the north end heavier than the south, and thus occasioning the needle to dip.

The method of giving the needle its verticity or directive faculty, has been shewn already under the article MAGNET; but if after touching, the needle be out of its equilibrium, something must be filed off from the heavier side, till it balance evenly.

Needles in sea-compasses are usually made of a rhomboidal or oblong form: we have given their structure already under the article COMPASS.

The needle is not found to point precisely to the north, except in very few places, but deviates from it more or less in different places, and that too at different times, which deviation is called its declination or variation from the meridian. See the article VARIATION.

*Dipping-NEEDLE*, a magnetical needle, so hung as that, instead of traversing horizontally and pointing out north and south, one end dips or inclines to the horizon, and the other points to a certain degree of elevation above it.

Or a dipping-needle may be defined, with Mr. Whiston, to be a long straight piece of steel, every way poised on its center, and afterwards touched

with a loadstone, but so contrived as not to play on the point of a pin, as does the common horizontal needle, but to swing in a vertical plane, about an axis parallel to the horizon; and this to discover the exact tendency of the power of magnetism. See *DIPPING-Needle*.

*NEEDLE-FISH*, a species of *syngnathus*, with the middle of the body hexangular, and the tail pin-nated.

*NEEDLE-SHELL*, in natural history, the slender *turbo*, with ventricose spires, and a small round mouth.

*NEGATION*, in logic, an act of the mind, affirming one thing to be different from another; as that the soul is not matter.

*NEGATIVE*, in general, something that implies a negation: thus we say, negative quantities, negative signs, negative powers, &c.

Our words and ideas, says Dr. Watts, are so unhappily linked together, that we can never know which are negative, which positive ideas, by the words that express them: for some positive terms denote a negative idea, as *dead*; and there are both positive and negative terms invented to signify the same and contrary ideas, as *unhappy* and *miserable*. To this may also be added, that some words, which are negative in the original language, seem positive in English, as *abyss*. The way, therefore, to know whether any idea be negative or not, is to consider whether it primarily implies the absence of any positive being, or mode of being; if so, then it is a negative idea, otherwise a positive one.

According to logicians, the only way to prove a negative, is by converting it into an affirmative.

*NEGATIVE PREGNANT*, a negative that implies or brings forth an affirmative; as where a person is impleaded to have done a certain thing on such a day, &c. and denies the thing generally, without alledging any thing farther; it is a negative pregnant plea, because such plea may nevertheless imply that he did it in some sort.

*NEGROES*, properly the inhabitants of Nigritia in Africa, also called blacks and moors; but this name is now given to all the blacks.

The origin of the negroes, and the cause of this remarkable difference from the rest of the human species, has much perplexed the naturalists: Mr. Boyle has observed, that it cannot be produced by the heat of the climate: for though the heat of the sun may darken the colour of the skin, yet experience does not shew that it is sufficient to produce a true blackness, like that of the negroes.

In Africa itself, many nations of Ethiopia are not black, nor were there any blacks originally in the West-Indies. In many parts of Asia, under the same parallel with the African region, inhabited by blacks, the people are but tawney. He adds, that there are negroes in Africa beyond the southern tropic, and that a river sometimes parts nations, one

of which is black and the other only tawney. Dr. Barriere alledges, that the gall of negroes is black, and being mixed with their blood, is deposited between their skin and scarf-skin. However, Dr. Mitchel, of Virginia, in the Philosophical Transactions, N<sup>o</sup>. 476, has endeavoured, by many learned arguments, to prove, that the influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of negroes, Indians, &c. and indeed it would be a strong confirmation of his doctrine, if we could see any people originally white, become black and woolly by transplantation, or *vice versa*.

Negroes are brought from Guinea, and other coasts of Africa, and sent into the colonies in America, to cultivate tobacco, sugar, indigo, &c. and in Mexico and Peru, to dig in the mines; and this commerce, which is scarce defensible on the foot either of religion or humanity, is now carried on by all the nations that have settlements in the West Indies. Those negroes make the best slaves, who are brought from Angola, Senegal, Cape Verd, the river Gambia, the kingdoms of Joloffes, Daniel, Galland, &c.

There are various ways of procuring them: some, to avoid famine, sell themselves, their wives, and children, to their princes, or other great men; others are made prisoners of war; and great numbers are seized in excursions made for that very purpose by the petty princes upon one another's territories, in which it is usual to sweep away all, without distinction to age or sex.

NEHEMIAH, a canonical book of the Old Testament, so called from the name of its author. Nehemiah was born at Babylon, during the captivity, and succeeded Ezra in the government of Judah and Jerusalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus, king of Persia; when the opportunities he had of being daily in the king's presence, together with the favour of Esther the queen, procured him the favour of being authorized to repair and fortify the city of Jerusalem, in the same manner as it was before its destruction by the Babylonians. On his going to Jerusalem, he finished the rebuilding of the walls in fifty-two days, and dedicated the gates of the city with great solemnity. He then reformed some abuses which had crept in among his countrymen, particularly the extortion of the usurers, by which the poor were so oppressed as to be forced to sell their lands and children for support: after which he returned to Persia, and came back again with a new commission, by virtue of which he regulated every thing relating both to the state and religion of the Jews. The history of these transactions is the subject of this book.

NEMÆAN GAMES, were so called from Nemæa, a village between the cities of Cleonæ and Philus, where they were celebrated every third

year. The exercises were chariot-races, and all the parts of the pentathlon. These games were instituted in memory of Opheltus, or Archemorus, the son of Euphetes and Creusa, and nursed by Hypsipyle; who leaving him in a meadow, while she went to shew the besiegers of Thebes a fountain, at her return found him dead, and a serpent twined about his neck: whence the fountain, before called Langia, was named Archemorus; and the captains, to comfort Hypsipyle, instituted these games. Others ascribe their institution to Hercules, after his victory over the Nemæan lion.

NENIA, or NÆNIA, in ancient poetry, a mournful kind of song, filled with the praises of some deceased person, and sung during the celebration of the funeral. See the article FUNERAL.

NEOMENIA, or NOUMENIA, a festival of the ancient Greeks, at the beginning of every lunar month, which was, as the name imports, observed upon the day of the new-moon, in honour of all the gods, but especially Apollo, who was called Neomenios; because the sun is the fountain of light, and whatever distinction of times and seasons may be taken from other planets, yet they are all owing to him as the original of those borrowed rays by which they shine.

NEOPHYTES, new plants, a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism.

The term neophytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the Infidels.

NEOTTIA, bird's nest, in botany, a genus of plants, the flower of which consists of five ovato-oblong petals, connivent at the points: the nectarium is undivided, equal in length to the petals, and furnished with a denticulation on each side: the fruit is a rugose oblong capsule, containing a great number of seeds.

NEPA, the lesser furz, in botany, a species of *genista spartium*.

NEPENTHES, in botany, a genus of plants, whose flower is apetalous; the calyx is divided into four segments, and the filaments are scarce visible, the antheræ joining to the top of the style. The fruit is an oblong, columnar, truncated capsule, having four cells, which contain a number of chaffy acuminated seeds.

NEPER'S RODS, or BONES, an instrument invented by J. Neper, baron of Marchifston, in Scotland, whereby the multiplication and division of large numbers are much facilitated.

NEPETA, the tall white sideritis, or catmint, in botany, a genus of plants, the corolla whereof consists of a single ringent petal, the tube is cylindric and incurvated, and the limb dehiscent; the faux

is patent, cordated, and terminating in two short segments; the upper lip is erect, roundish, and emarginated; the lower one is a roundish, concave, large, entire and serrated; there is no pericarpium, but the seeds, which are roundish, and four in number, are contained in the cup.

Catmint has been greatly recommended as an uterine and nervous medicine. The people in the country still frequently use it in form of an infusion for these purposes, but in the shops it is only kept as an ingredient in some compositions.

NEPHEW, a term relative to uncle and aunt, signifying a brother's or sister's son; who, according to the civil law, is in the third degree of consanguinity, but according to the canon in the second.

NEPHRITIC, something that relates to the kidneys. See kidneys.

NEPHRITIC STONE, *Lapis Nephriticus*. See STONE.

NEPHRITIC WOOD, *Lignum Nephriticum*, a wood of a very dense and compact texture, and of a fine grain, brought us from New Spain, in small blocks, in its natural state, and covered with its bark. It is to be chosen of a pale colour, sound, and firm, and such as has not lost its acrid taste; but the surest test of it is the infusing it in water: for a piece of it infused half an hour in cold water, gives it a changeable colour; which is blue or yellow, as variously held to the light. If the vial it is in be held between the eye and the light, the tincture appears yellow; but if the eye be placed between the light and the vial, it appears blue. We often meet with this wood adulterated with others of the same pale colour; but the dusky black hue of the bark, is a striking character of this.

The tree is the coatli of Hernandez. It grows to the height of our pear-tree, and its wood, while fresh, is much of the same texture and colour; the leaves are small and oblong, not exceeding half an inch in length, or a third of an inch in breadth; the flowers are small, and of a pale yellow, and oblong shape, standing in spikes; the cups they stand in are divided into five segments at the edge, and are covered with a reddish down. This is the best description of the tree that can be collected from what has been hitherto written of it; no body having had an opportunity of taking its true characters.

This wood is a very good diuretic, and is said to be of great use with the Indians in all diseases of the kidneys and bladder, and in suppressions of urine, from whatever cause. It is also recommended in fevers and obstructions of the viscera. The way of taking it, among the Indians, is only an infusion in cold water.

NEPHRITICS, in pharmacy, medicines proper for diseases of the kidneys, especially the stone. See STONE.

Such particularly are the roots of althæa, dog's-grass, asparagus, fago, pellitory of the wall, mallows, pimpinella, red chick-pease, peach-kernels, turpentine, the nephritic wood, &c. and diuretics. See diuretics, &c.

NEPHRITIS, in medicine, an inflammation of the kidneys.

The symptoms of the Nephritis, according to Boerhaave, are a great inflammatory, pungent, burning pain in the place where the kidneys are situated, attended with a fever. The urine is made often, but small in quantity, and very red, or flame-coloured; yet, in the highest degree of the disease, watery. There is a numbness of the thigh, a pain in the groin, and the testicle of the same side, a pain in the ilium, bilious vomiting, and continual eructations.

When the inflammation is deep, says Hoffman, the fever violent, the burning pain in the loins lasting, the difficulty of making water great, the body very costive, the anxiety and straitness of the precordia exquisite, the urine crude and white, and finally, when the pain continues to the fourteenth day, the kidney will suppurate, which is known from the abatement of the pain, and from the thick, purulent sediment of the urine. This will sometimes last several years, till there is nothing left of the kidney but a bag. This is attended with a hectic fever, and the patient before he dies is almost reduced to a skeleton. If the bag happens to burst, it brings on a retention of urine, and intolerable pains, which end in death.

When the disease is favourable, it is cured, according to Boerhaave, by resolution, or a copious red and thick urine discharged at one time; or, by a large flux of blood from the hæmorrhoidal veins, in the beginning of the disease. It is cured also by plentiful bleeding, revulsion, and dilution; and by soft emollient, antiphlogistic decoctions. Hoffman thinks emollient clysters without any saline or purging stimulus, the principal help in this disease. They may be made of milk, whey, or soft water, in which elder and camomile-flowers have been boiled; to which add an ounce or two of syrup of marsh-mallows, and a dram of nitre. The body should be kept open with oil of sweet almonds; and wind in the bowels should be discussed; for which purpose cummin seeds made into comfits are proper. When there are convulsions, or excessive pains, Boerhaave says, that opiates are proper; and that, if the vomiting, a symptom of this disease, is too frequent, warm water sweetened with honey, is beneficial. The patient should avoid all acrimonious aliment; he should neither lie too hot, nor on his back. By this method likewise, a nephritis arising from a stone in the kidneys, or ureters, may be cured. When an abscess is formed, the medicines must be powerfully maturing and emollient.

When

When the urine appears purulent, they must be diuretics of medicated waters, whey, and the like, together with balsamics. In this case, Hoffman recommends emulsions of the four cold seeds, and sweet almonds; some attribute a great virtue to cherry-tree gum dissolved in whey and water, and taken often. A syrup of marsh-mallows is very useful; add to these the decoction of veronica, sweetened with honey, mixt with powder of nutmegs.

Arbuthnot says, that butter-milk, not very sour, has been reckoned a great secret in ulcers of the kidneys; and that chalybeat waters have been beneficial to some: he says, that spruce-beer is a good balsamic in this case, and advises soft malt liquors rather than wine. If the disease ends in a schirrous, there will be a palsy, or a lameness of the adjacent thigh, says Boerhaave, as also an incurable evil; whence will proceed a renal tabes. When there is a sudden remission of the pain, a cold sweat, a weak intermitting pulse, hiccoughing, a stoppage of urine; or when it is livid, black, full of hairs, fetid, abounding with brown or black caruncles, and a sudden loss of strength, there is a mortal gangrene.

NEPOTISM, a term used in Italy, in speaking of the authority which the popes nephews and relations have in the administration of affairs, and of the care the popes take to raise and enrich them. Many of the popes have endeavoured to reform the abuses of nepotism, which at present is said to be abolished.

NERIUM, the oleander, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is cylindrical, the limb is large, and divided into five broad obtuse segments, which are oblique; a short nectarium terminates the top of the tube, which is torn into hairy segments; the stamina are five very short subulated filaments, topped with arrow-shaped antheræ, and join together. The fruit is two long subulated pods, which are filled with oblong seeds placed in an imbricated order, and crowned with down. The common oleander is preserved in our green-houses in winter; it flowers in July and August, and makes an agreeable appearance. Another species, commonly called the double oleander, is very beautiful; but being tender, requires a hot-house to preserve it; they are easily propagated by laying down their branches in the summer.

NERVES, *Nervi*, in anatomy, are cylindrical whitish parts, usually fibrous in their structure; or composed of clusters of filaments, arising from the brain, or rather from its medulla oblongata within the skull, and from the spinal marrow, and running from thence to every part of the body.

*Structure and Use of the NERVES.* This is easily perceived in most of the larger, and some of the smaller ones: for besides the blood-vessels they receive, and the membranes they are surrounded with,

they are seen to be composed of a fibrous matter; or, as it were, of bundles or clusters of white, cylindrical, and very slender filaments; which, on the strictest examination, appear to be solid, and without any cavity. Liewenhoeck indeed affirms, that he had often found a cavity in them; but he is not free from errors in many of his microscopical observations. But though we cannot discover any cavity, much less a fluid in them; yet it is very possible that there may be such cavities, and such a fluid, only too small to be perceived by us: and for the actual existence of such a fluid, known by the name of animal spirits, many probable arguments are adduced.

The great use of the nerves, therefore, though we are not able perfectly to demonstrate it, seems to be to convey to all parts of the body a fluid of an extremely subtle kind, secreted in the brain and spinal marrow, and destined for no less noble a purpose than the sensation, motion, and nutrition of the several parts of the whole human fabric.

The ancients found, that by cutting, tying, or compressing any nerve, or any other way intercepting its communication with the brain, the parts to which it belonged were immediately deprived of all sense and motion. One remarkable instance of this is, the making an animal dumb by tying the nerves near the wind pipe. We read in Galen, of a boy who became quite dumb by having both the recurrent nerves divided. The experiment of cutting these nerves in brute animals, was repeated and confirmed by Vesalius; and Dr. Martin assures us, he tried it successfully on a pig; nor did the animal recover its voice, as some have suspected it might. As the voice depends on a proper aperture of the glottis, it seems likely that, when the recurrent nerves are cut, the glottis will always stand open, and be incapacitated from being shut at the will of the animal. An anonymous physician offers what he calls an experimentum crucis, in proof of the nerves being composed of cylindrical canals, containing a fluid: it is the demonstration of the optic nerve inflated and dried, which appears canular to the naked eye.

*Wounds of the NERVES.* Upon the division of a nerve, Heister observes, that the limb to which that nerve was extended becomes instantly rigid, void of sensation, and withers: so that it is no wonder that a man instantly expires, upon the division of those nerves which are sent to the heart or diaphragm: a wound is also attended with great danger where the nerve is partially wounded, and not entirely divided; for the wounded fibres contract themselves, and those which remain undivided suffer too great an extension, which will bring on most violent pains, spasms, convulsions, inflammations, and gangrenes, and sometimes death itself.

NESTORIANS, a Christian sect, the followers of Nestorius, bishop and patriarch of Constantinople;

ple; who, about the year 429, taught that there were two persons in Jesus Christ, the divine and the human, which are united, not hypostatically or substantially, but in a mystical manner: whence he concluded, that Mary was the mother of Christ and not the mother of God. For this opinion, Nestorius was condemned and deposed by the council of Ephesus; and the decree of this council was confirmed by the emperor Theodosius, who banished the bishop to a monastery.

Those Christians who at this day are called Nestorians and Chaldeans, are very numerous, and are spread over Mesopotamia, and along the river Tigris and Euphrates: they are even got into the Indies, and into Tartary and China. Those of India settled there under a Nestorian priest called John, who, in the year 1145, got himself declared king of Indostan, and grew very famous under the name of Prester John. The Nestorians, though they speak the language of the respective countries, only officiate in the Chaldee or Syriac tongue. The Nestorian monks are habited in a black gown tied with a leathern girdle, and wear a blue turban. The nuns are dressed much after the same manner, excepting that they tie a kind of black veil about their heads and about their chins. They must be forty years old before they take the monastic habit.

NET, a device for catching fish and fowl.

The taking fowls by nets, is the readiest and most advantageous of all others, where numbers are to be taken. The making the nets is very easy, and what every true sportsman ought to be able to do for himself. All the necessary tools are wooden needles, of which there should be several of different sizes, some round and others flat: a pair of round-pointed and flat scissars, and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should neither be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread. The natural colour of the thread is too bright and pale, and is therefore in many cases to be altered. The most usual colour is the russet, which is to be obtained by plunging the net after it is made, into a tanner's pit, and letting it lie there till it be sufficiently tinged: this is of a double service to the net, since it preserves the thread as well as alters the colour. The green colour is given by chopping some green wheat and boiling it in water, and then soaking the net in this green tincture. The yellow colour is given in the same manner with the decoction of celandine, which gives a pale straw-colour, which is the colour of stubble in the harvest-time. The brown nets are to be used on ploughed lands, the green on grass grounds, and the yellow on stubble lands.

NETTINGS, among seamen, a sort of grating formed of cordage fastened regularly together at equal distances, so as to resemble a net; they are fixed on the quarter-rails, the intervals of which they fill up, being partly for ornament and partly for use; as to prevent any body on the deck from tumbling over-board, as the ships rocks from side to side. In a ship of war they have double rows of nettings, about eighteen inches distant from each other, these are supported by small iron pillars, called stanchions, and the vacancy between is filled up with the hammocks and bedding of the sailors, to serve as a fence in the time of action. The fore-castle and the tops of large ships are also generally furnished with nettings.

NETTLE, *Urtica*, in botany, a genus of plants, producing male and female flowers; the male flowers, instead of petals, have a small nectarium placed in the center, with four filaments topped with bilocular antheræ. The female flowers have no corolla; the germen is oval, and the stigma hairy: the seed is single, oval, and obtusely compressed, and placed in the cup. There are several kinds of nettles, as the common nettle, the lesser stinging-nettle, the Roman nettle, &c. The juice of this plant is recommended to stop spitting of blood, and other hæmorrhages; the leaves are diuretic, and good in the gout, rheumatism, stone, and gravel; and are frequently used in the spring to cleanse and purify the blood. The seeds and roots of nettles are said to be a good remedy against the jaundice, and to promote expectoration in coughs, as well as in the asthma and pleurisy.

Dead NETTLE, *Lamium*, in botany. See the article LAMIUM.

NETTLE-TREE, *Celtis*, in botany. See the article CELTIS.

NEURADA, in botany, a genus of plants, the flower of which consists of five equal petals, and its fruit is an orbiculated depressed capsule, convex on the under part, and every where armed with ascending prickles: it contains ten cells, in each of which is a single seed.

NEUTER, or NEUTER-GENDER, in grammar, one of the three genders of nouns, so called as being neither masculine nor feminine. See the article GENDER.

NEUTER-VERBS. See the article VERB.

NEUTRAL-SALTS, among chemists, a sort of salts neither acid nor alkaline, but partaking of the nature of both. See the articles ACID and ALKALI.

NEUTRALITY, the state of a person or thing that is neuter, or that takes part with neither side.

NEW-MOON, *Neomenia*, strictly speaking, is the state of the moon a little after her conjunction with the sun; though it is often used for the conjunction itself. See MOON and NEOMENIA.

NEWEL,

**NEWEL**, in architecture, is the upright post which a pair of winding stairs turn about: this is properly a cylinder of stone which bears on the ground, and is formed by the end of the steps of the winding-stairs. There are also newels of wood, which are pieces of timber placed perpendicularly, receiving the tenants of the steps of the wooden stairs into their mortices, and on which are fitted the shafts and rests of the stair case, and the flights of each story.

**NEWTONIAN PHILOSOPHY**, the doctrine of the universe, and particularly of the heavenly bodies; their laws, affections, &c. as delivered by Sir Isaac Newton.

The term Newtonian philosophy is applied very differently by different authors. Some, under this philosophy, include all the corpuscular philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in the several parts thereof by Sir Isaac Newton. In this sense it is that s<sup>r</sup> Gravesande calls his *Elements of Physics*, an Introduction to the Newtonian Philosophy; and in this sense, the Newtonian is the same with the new philosophy, in opposition to the Cartesian, the peripatetic, and the antient corpuscular philosophy. See **CARTESIAN**, &c. Others, by Newtonian philosophy, mean the method or order which Sir Isaac observes in philosophizing, viz. the reasoning and drawing of conclusions directly from phænomena, exclusive of all previous hypotheses; the beginning from simple principles, deducing the first powers and laws of nature from a few select phænomena, and then applying those laws, &c. to account for other things: and in this sense, the Newtonian is the same with the experimental philosophy.

Others again, by Newtonian philosophy, mean that wherein physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of phænomena; in which sense, the Newtonian is the same with the mechanical and mathematical philosophy.

Others again, by Newtonian philosophy, understand that part of physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated in his *Principia*.

And, lastly, others, by Newtonian philosophy mean the new principles which Sir Isaac has brought into philosophy, the new system founded thereon, and the new solutions of phænomena thence deduced; or that which characterizes and distinguishes his philosophy from all others: and this is the sense in which we shall chiefly consider it.

As to the history of this philosophy, we have but little to say: it was first made public in 1686, by the author, then a fellow of Trinity-college, Cambridge; and in the year 1713, republished with considerable improvements. Several other authors have since attempted to make it plainer, by setting

aside many of the more sublime mathematical researches, and substituting either more obvious reasonings or experiments in lieu thereof; particularly Mr. Whiston, in his *Prelect. Phys. Mathem.* s<sup>r</sup> Gravesande, in his *Elem. and Inst.* and lately, by the learned Comment of Le Seur and Jacquier upon Sir Isaac's *Principia*.

The philosophy itself is laid down chiefly in the third book of the *Principia*; the two preceding books being taken up in preparing the way; and laying down such principles of mathematics as have the most relation to philosophy: such are the laws and conditions of powers; and these, to render them less dry and geometrical, the author illustrates by scholia in philosophy, relating chiefly to the density and resistance of bodies, the motion of light and sounds, a vacuum, &c.

In the third book he proceeds to the philosophy itself; and from the same principles deduces the structure of the universe, and the powers of gravity, whereby bodies tend towards the sun and planets; and, from these powers, the motions of the planets and comets, the theory of the moon and the tides.

This book, which he calls *De Mundi Systemate*, he tells us, was first wrote in the popular way; but considering, that such as are unacquainted with the said principles, would not conceive the force of the consequences, nor be induced to lay aside their antient prejudices; for this reason, and to prevent the thing from being in continual dispute, he digested the sum of that book into propositions, in the mathematical manner, so as it might only come to be read by such as had first considered the principles; not that it is necessary a man should master them all; many of them, even the first rate mathematicians, would find a difficulty in getting over. It is enough to have read the definitions, laws of motion, and the three first sections of the first book; after which, the author himself directs us to pass on to the book *De Systemate Mundi*.

The great principle on which the whole philosophy is founded, is the power of gravity: this principle is not new: Kepler, long ago, hinted it in his *Introduct. ad Mot. Martis*. He even discovered some of the properties thereof, and their effects in the motions of the primary planets; but the glory of bringing it to a physical demonstration, was reserved to the English philosopher. See the article **GRAVITATION**.

His proof of this principle from phænomena, together with the application of the same principle to the various other appearances of nature, or the deducing those appearances from that principle, constitute the Newtonian system: which, drawn in miniature, will stand thus:

I. The phænomena are, 1. That the satellites of Jupiter do, by radii drawn to the center of the planet, describe areas proportional to their times; and that their periodical times are in a sesquuplicate ratio of

of their distances from its center; in which the observations of all astronomers agree. 2. the same phenomenon holds of the satellites of Saturn, with regard to Saturn; and of the moon with regard to the earth. 3. The periodical times of the primary planets about the sun, are in a sesquuplicate ratio of their mean distances from the sun. But, 4. The primary planets do not describe areas any way proportional to their periodical times, about the earth; as being sometimes seen stationary, and sometimes retrograde, with regard thereto.

2. The powers whereby the satellites of Jupiter are constantly drawn out of their rectilinear course, and retained in their orbits, respect the center of Jupiter, and are reciprocally as the squares of the distances from the same center. 2. The same holds of the satellites of Saturn, with regard to Saturn; of the moon, with regard to the earth; and of the primary planets, with regard to the sun.

3. The moon gravitates towards the earth, and by the power of that gravity is retained in her orbit; and the same holds of the other satellites, with respect to their primary planets; and of the primaries, with respect to the sun.

As to the moon, the proposition is thus proved: the moon's mean distance is 60 semi-diameters of the earth; her period, with regard to the fixed stars, is 27 days, 7 hours, 43 minutes; and the earth's circumference 123249600 Paris feet. Now, supposing the moon to have lost all her motion, and to be let drop to the earth, with the power which retains her in her orbit, in the space of one minute she will fall  $15\frac{1}{2}$  Paris feet; the arch she describes in her mean motion, at the distance of 60 diameters of the earth, being the versed sine of  $15\frac{1}{2}$  Paris feet. Hence, as the power, as it approaches the earth, increases in a duplicate ratio of the distance inversely; so as at the surface of the earth it is  $60 \times 60$  greater than at the moon; a body falling with that force in our region must, in a minute's time, describe the space of  $60 \times 60 \times 15\frac{1}{2}$  Paris feet, and  $15\frac{1}{2}$  Paris feet in the space of one second.

But this is the rate at which bodies fall by their gravity at the surface of our earth; as Huygens has demonstrated by experiments with pendulums. Consequently, the power whereby the moon is retained in her orbit, is the very same we call gravity; for, if they were different, a body, falling with both powers together, would descend with double the velocity, and in a second of time describe  $30\frac{1}{2}$  feet.

As to the other secondary planets, their phenomena, with respect to their primary ones, being of the same kind with those of the moon about the earth, it is argued by analogy, they depend on the same causes; it being a rule or axiom all philosophers agree to, that effects of the same kind have the same causes.

Again, attraction is always mutual, i.e. the reaction is equal to the action: consequently, the pri-

mary planets gravitate towards their secondary ones, the earth towards the moon, and the sun towards them all. And this gravity, with regard to each several planet, is reciprocally as the square of its distance from the center of gravity.

4. All bodies gravitate towards all the planets; and their weight towards any one planet; at equal distances from the center of the planet, is proportional to the quantity of matter in each.

For the law of the descent of heavy bodies towards the earth, setting aside their unequal retardation from the resistance of the air, is this, that all bodies fall equal spaces in equal times; but the nature of gravity or weight, no doubt, is the same on the other planets as on the earth.

Suppose, e.g. such bodies raised to the surface of the moon, and together with the moon deprived at once of all progressive motion, and dropped towards the earth: it is shewn, that in equal times they will describe equal spaces with the moon; and therefore, that quantity of matter is to that of the moon, as their weights to its weight.

Add, that since Jupiter's satellites revolve in times that are in a sesquuplicate ratio of their distances from the center of Jupiter, and consequently at equal distances from Jupiter, their accelerating gravities are equal; therefore, falling equal altitudes in equal times, they will describe equal spaces; just as in heavy bodies on our earth. And the same argument will hold of the primary planets with regard to the sun, and the powers whereby unequal bodies are equally accelerated, are as the bodies, i.e. the weights are as the quantities of matter in the planets, and the weight of the primary and secondary planets towards the sun, are as the quantities of matter in the planets and satellites. See the article JUPITER.

And hence are several corollaries drawn relating to the weights of bodies on the surface of the earth, magnetism, and the existence of a vacuum.

5. Gravity extends itself towards all bodies, and is in proportion to the quantity of matter in each.

That all planets gravitate towards each other, has been already shewn; likewise, that the gravity towards any one, considered apart, is reciprocally as the squares of its distance from the center of the planet; consequently, gravity is proportionable to the matter therein.

Farther, as all the parts of any planet A, gravitate towards another planet B; and the gravity of any part is to the gravity of the whole, as the matter of the part to the matter of the whole; and re-action equal to action: the planet B will gravitate towards all the parts of the planet A; and its gravity towards any part will be to its gravity towards the whole, as the matter of the part to the matter of the whole.

Hence we derive the methods of finding and comparing weights of bodies towards different planets; of

of finding the quantity of matter in the several planets, and their densities; since the weights of equal bodies, revolving about planets, are as the diameter of their orbits directly, and as the squares of the periodical times inversely; and the weights at any distance from the center of the planet, are greater or less in a duplicate ratio of their distances inversely. And since the quantities of matter in the planets are as their powers at equal distances from their centers: and lastly, since the weights of equal and homogeneous bodies towards homogeneous spheres are, at the surfaces of the spheres, as the diameters of those spheres; and consequently, the densities of heterogeneous bodies, are as the weights at the diameters of the spheres.

6. The common center of gravity of the sun, and all the planets is at rest; and the sun, though always in motion, yet never recedes far from the common center of all the planets.

For the matter in the sun being to that in Jupiter as 1033 to 1; and Jupiter's distance from the sun to the semi-diameter of the sun in a ratio somewhat bigger; the common center of gravity of Jupiter and the sun will be a point a little without the sun's surface; and by the same means, the common center of Saturn and the sun will be a point a little within the sun's surface; and the common center of the earth, and all the planets, will be scarce one diameter of the sun distant from the center thereof: but the center is always at rest; therefore, though the sun will have a motion this and that way, according to the various situations of the planets, yet it can never recede far from the center; so that the common center of gravity of the earth, sun, and planets, may be esteemed the center of the whole world.

7. The planets move in ellipses that have their foci in the center of the sun, and describe areas proportionable to their times. This we have already laid down *à posteriori*, as a phenomenon; and now, that the principle of the heavenly motions is shewn, we deduce it therefrom *à priori*. Thus, since the weights of the planets towards the sun are reciprocally, as the squares of their distances from the center of the sun; if the sun were at rest, and the other planets did not act on each other, their orbits would be elliptical, having the sun in the common umbilicus, and would describe areas proportionable to the times; but the mutual actions of the planets are very small, and may be well thrown aside.

Indeed, the action of Jupiter on Saturn is of some consequence; and hence, according to the different situation and distances of those two planets, their orbits will be a little disturbed. The earth's orbit too is sensibly disturbed by the action of the moon; and the common center of the two describes an ellipsis round the sun placed in the umbilicus; and, with a radius drawn to the center of the sun, describes areas proportionable to the times.

8. The aphelia and nodes of the planets are at rest, excepting for some inconsiderable irregularities arising from the action of the revolving planets and comets. Consequently, as the fixed stars retain their position to the aphelia and nodes, they too are at rest.

9. The axis, or polar diameter, of the planets, is less than the equatorial diameter.

The planets, had they no diurnal rotation, would be spheres, as having an equal gravity on every side: but by this rotation, the parts receding from the axis endeavour to rise towards the equator, which, if the matter they consist of be fluid, will be affected very sensibly. Accordingly, Jupiter, whose density is found not much to exceed that of water on our globe, is observed by astronomers to be considerably less between the two poles, than from east to west. And, on the same principle, unless our earth were lighter at the equator than towards the poles, the sea would rise under the equator, and overflow all near it. But this figure of the earth Sir Isaac Newton proves likewise *à posteriori*, from the oscillations of pendulums being slower and smaller in the equinoxial, than in the polar parts of the globe. See the article EARTH.

10. All the moon's motions, and all the inequalities of these motions, follow from these principles, e. g. her unequal velocity, and that of her nodes and apogee in the syzygies and quadratures; the differences in her eccentricity and her variation. See MOON.

11. From the inequalities of the lunar motions, we can deduce the several inequalities in the motions of the satellites.

12. From these principles, particularly the action of the sun and moon upon the earth, it follows, that we must have tides, or that the sea must swell and subside twice every day.

13. Hence, likewise, follows the whole theory of comets, as that they are above the region of the moon, and in the planetary spaces; that they shine by the sun's light, reflected from them; that they move in conic sections, whose umbilici are in the center of the sun; and, by radii drawn to the sun, describe areas proportional to the times; that the orbits, or trajectories, are very nearly parabolas; that their bodies are solid, compact, &c. like those of the planets, and must therefore acquire an immense heat in their perihelia; that their tails are exhalations, arising from and encompassing them like atmospheres.

NICHE, in architecture, a hollow sunk into a wall, for the commodious and agreeable placing a statue.

The ordinary proportion of a niche is to have two circles in height and one in width; but M. Le Clerc makes their height something more, the excess being to compensate for the height of the pedestal of the statue. The hollow is semicircular at

bottom,

bottom, that is, in its plan; and at top it terminates in a kind of canopy. Niches have frequently an impost, and an archivolt or head-band, and the canopy wrought and enriched in the manner of a shell. The breadth of the archivolt may be made equal to a sixth or seventh part of the niche, and the height of the impost to a fifth or sixth part of the same: and the impost and archivolt ought to consist of such mouldings as have some relation to the architecture of the place. Niches are sometimes made with rustic-work, sometimes with shell-work, and sometimes of cradle or arbour-work. Niches are sometimes made square, but these want all the beauty of the others.

**NICOLAITANS**, in church history, Christian heretics who assumed this name from Nicolas of Antioch; who, being a gentile by birth, first embraced Judaism, and then Christianity; when his zeal and devotion recommended him to the church of Jerusalem, by whom he was chosen one of the first deacons.

Many of the primitive writers believe, that Nicolas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the spirit of God himself, Apoc. ii. 6. And, indeed, their opinions and actions were highly extravagant and criminal. They allowed a community of wives; made no difference between ordinary meats and those offered to idols; and told I know not what fables of the creation and disposition of the world.

According to Eusebius, they subsisted but a short time; but Tertullian says, they only changed their name, and that their heresies passed into the sect of the Cainians. See **CAINIANS**.

**NICOTIANA**, tobacco, in botany. See the article **TOBACCO**.

**NICTITATING MEMBRANE**, in comparative anatomy, a thin membrane, chiefly found in the bird and fish-kind, which covers the eyes of these animals, sheltering them from the dust or too much light; yet is so thin and pellucid, that they can see pretty well through it.

**NIDUS**, among naturalists, signifies a nest, or proper repository for the eggs of birds, insects, &c. wherein the young of these animals are hatched and nursed.

**NIECE**, a brother or sister's daughter; which in the civil law is reckoned the third degree of consanguinity.

**NIGELLA**, fennel-flower, in botany, a genus of plants, whose flower consists of five ovate, plain, obtuse petals, contracted at their base, and eight very short nectariums, placed in a circle and bilabiated: the filaments are numerous, subulated, and shorter than the petals; these are topped with upright, obtuse, compressed antheræ: the germina are either five or ten, which become so many oblong, com-

pressed, acuminate capsules, which are filled with rough angulated seeds.

**NIGHT**, that part of the natural day during which the sun is underneath the horizon; or that space wherein it is dusky. See **DAY**.

Night was originally divided by the Hebrews, and other eastern nations, into three parts, or watchings. The Romans, and afterwards the Jews from them, divided the night into four parts, or watches; the first of which began at sun-set, and lasted till nine at night, according to our way of reckoning; the second lasted till midnight; the third till three in the morning; and the fourth ended at sun-rise. The ancient Gauls and Germans divided their time not by days but by nights; and the people of Iceland and the Arabs do the same at this day. The like is also observed of our Saxon ancestors.

**NIGHT-MARE**, in medicine, a disease called by physicians ephialtes and incubus. See the article **INCUBUS**.

**NIGHT-WALKERS**, *Noctambuli*. See the article **NOCTAMBULI**.

**NIGHTINGALE**, *Luscinia*, in ornithology, the brownish-grey motacilla, with the annules of the knees grey.

This bird is more eminent for the sweetness of its note, than for its beauty: it is of the size of the linnet, but in shape it more resembles the red-breast; the head is small, the eyes are large, and their iris pale; the beak is dusky, slender, and moderately long; the head, neck, and back, are of a greyish-brown; the upper parts of the wings, and about the tail, have a tinge of reddish mixed with this; and the throat, breast, and belly, are of a pale whitish grey.

**NIGHTSHADE**, *Solanum*, in botany. See the article **SOLANUM**.

*Deadly* NIGHTSHADE. See **ATROPA**.

**NIHILS**, or **NICHILS**, issues which a sheriff, who is opposed in the exchequer, says are nothing worth, and not to be levied, through the insufficiency of the parties from whom the same are due.

**NIMBUS**, in antiquity, a circle observed on certain medals, or round the head of some emperors, answering to the circles of light, drawn around the images of saints.

The nimbus is seen on the medals of Maurice, Phocas, and others, even of the upper empire.

**NIPPERS**, in the manege, are four teeth in the fore-part of a horse's mouth, two in the upper and two in the lower jaw. A horse puts them forth between the second and third year. See the article **TOOTH**.

**NIPPERS**, is also an instrument used among smiths and farriers; being a kind of pincers, where-with, in shoeing a horse, they cut the nails before they rivet them. It is also used in taking off a shoe.

**NIPPERS**, in the marine, certain pieces of flat platted cordage, employed in heaving in the cable of a ship of war. See the articles MESSENGER and VOYAL.

When the cable is drawn into the ship by the force of the capstern, there is always a rope of a smaller size, which is more convenient and pliable than the cable, wound about the capstern; this rope is termed the voyal or messenger: it is fastened in several places to the cable, by the nippers, as the cable comes in.

These nippers are generally about seven, eight, or nine feet in length, in proportion to the size of the cable: they are clapped on the cable as soon as it enters the fore-part of the ship, and are taken off as soon as they reach about the middle of the deck, that the cable may be coiled away below, with all convenient dispatch. There are generally five or six nippers on the cable at once; the boys of the ship walking along the deck with the ends of them in their hands, till they come to the place where it is necessary to take them off.

**NIPPLES**, *Papillæ*, in anatomy. See the article BREASTS.

**NIPPLE-WORT**, *Lappana*, in botany. See the article LAPSANA.

**NISI PRIUS**, in law, a judicial writ which lies in cases where the jury being impanelled and returned before the justices of the bank, one of the parties requests to have such a writ, for the ease of the country, in order that the trial may come before the justices in the same county on their coming thither. These trials by nisi prius are intended for the ease of the country, by saving the parties, jurors, and witnesses, the trouble of coming to Westminster. The purport of a writ of nisi prius is, that the sheriff is thereby commanded to bring to Westminster the men impanelled, at a certain day before the justices, "*Nisi prius justiciarii domini regis ad assisas capiendas venerint;*" that is, unless the justices go before the day into such a county to take assizes.

**NISSOLA**, in botany, a genus of plants, whose flower is papilionaceous, the vexillum is roundish and reflexed, the alæ are oblong, obtuse, and erect, which shut up the carina. The fruit is an oblong, cylindric capsule, containing often but one oblong seed.

**NITRARIA**, in botany, a genus of plants, whose flower consists of five oblong patent petals, with fifteen subulated filaments, topped with roundish anthers. The fruit is an ovate-oblong acuminate drupe, with one cell, containing one trilocular oval seed.

**NITRE**, or salt-petre, is a simple salt, which is pellucid, but sometimes whitish, and in its most perfect pieces is in the form of long and slender crystals, of a prismatic figure, of an equal thickness throughout their whole length, composed of six

planes or sides, and terminated at the end by a pyramid, which is small and short in proportion to the size of the column, but composed of the same number of planes. These sprigs vastly resemble the common sprig crystals of the rocks. Nitre is to be chosen in fair, long, and transparent crystals, and such as when applied to the tongue, affects it with a peculiar kind of coldness; such as when set on the fire easily melts, and on being thrown upon it, blazes very furiously, and emits a bright and vivid flame without crackling, and leaves only a very little fixed salt on the coals.

Nitre is found immersed in imperceptible particles in earthy substances; as the particles of metals in their ores; but sometimes it is found native and pure, in the form of an efflorescence or shapeless salt, either on its ore or on old walls. The earth from which nitre is made, both in Persia and the East-Indies, is a kind of marl, found on the bare cliffs on the sides of hills exposed to the northern or eastern winds, and never in any other situation. The people of those countries collect large quantities of this, and having a large and deep pit, which they line with a hard and tenacious kind of clay, they fill it half full of water, and into this they throw the earth; when this is broken and mouldered to powder, they add more water, and stirring all well together, they let it stand four or five days; after this they open a hole made in one of the sides of the pit, which lets out all the clear water into a channel of about a foot wide, which is in the same manner clayed within, through which it runs into another very wide and shallow pit, which is prepared in a level ground, and is secured by slight walls on all but the north-east side, and is open to the sun at the top; here the water by degrees evaporates, and the salt which it had imbibed from the earth, crystallizes into small, brownish-white hexaedra, but usually imperfect crystals, which are preserved; and this is the rough saltpetre we receive from the East-Indies. The far greater part of the nitre used in the world is prepared in this manner; though there are many other methods of procuring it. In several of the eastern nations, the ruins of old buildings exposed to the north and east winds, and sheltered from rain, have their walls covered with an efflorescence of a nitrous salt, which they throw into the solution of the salt from the ore, when it will no longer afford any crystals of itself, and by this addition it becomes capable of affording a large quantity of additional crystals like the first. Earths moistened or manured with the excrements of animals, as the earths of pigeon-houses, and the like, all afford more or less nitre; and vast quantities of this salt are annually made in France, by boiling in water the matter of old walls, the old plaster of ruined buildings, and the earths of stables and other places where animals have been fed.

Salt-petre is of very great use in the manufactures; besides

besides being the basis of gun-powder, it is used in the making of white glass, and is of the same use as common salt in preserving of foods.

Purified nitre is one of the capital remedies in medicine. It cools and thins the blood, and gives it a fine florid colour; and therefore in all inflammatory diseases attended with condensations of the blood, this salt proves excellently cooling and attenuating. It is greatly serviceable in pleurifies, peripneumonies and quinsies; in the suppression of urine, and in the small-pox.

NOBILITY, a quality that ennobles, and raises a person possessed of it above the rank of a commoner.

The origin of nobility in Europe is by some referred to the Goths; who, after they had seized a part of Europe, rewarded their captains with titles of honour, to distinguish them from the common people. In Britain the term nobility is restrained to degrees of dignity above knighthood; but every where else nobility and gentility are the same.

NOBLE, a money of account containing six shillings and eight-pence.

The noble was anciently a real coin, struck in the reign of Edward III. and then called the penny of gold; but it was afterwards called a rose-noble, from its being stamped with a rose.

NOCTILUCA, in physiology, a species of phosphorus, so called because it shines in the night without any light being thrown upon it; such is the phosphorus made of urine. See the article PHOSPHORUS.

NOCTURNAL, something relating to the night, in contradistinction to diurnal.

NOCTURNAL-ARCH, in astronomy, the arch of a circle described by the sun, or a star, in the night.

*Semi-NOCTURNAL arch of the Sun*, is that portion of a circle he passes over between the lower part of our meridian and the point of the horizon, wherein he arises; or between the point of the horizon wherein he sets, and the lower part of our meridian.

NOCTURNAL, *Nocturlabium*, an instrument formerly much used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude and hour of the night.

NODATED HYPERBOLA, a name given by Sir Isaac Newton, to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODE, *Nodus*, in surgery, a tumour arising on the bones, and usually proceeding from some venereal cause; being much the same with what is otherwise called exostosis.

NODES, in astronomy, the two points wherein the orbit of a plane intersects the ecliptic.

NODULE, or NODULUS, a word used in pharmacy, for a knot tied in a rag, and including some medicinal ingredients to be suspended in any liquor,

as beer, or wine, to give it a tincture, or the like.

It signifies also a parcel of odoriferous simples, tied up in a piece of silk, for the patient to be frequently smelling to.

NODUS, or NODE, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof, either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture, are shewn.

Nodus is also used for the hole in a ceiling of a room, or in the window, for making of a dial on the floor, wall, or the like.

NOERA, a word used by chemists, for the head of an alembec, or the cover of a cucurbite, or any other vessel used in distillation.

NOETIANS, in church-history, Christian heretics in the III<sup>d</sup> century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses, sent by God; and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations, given to God, in consequence of different operations; that as creator, he is called Father; as incarnate, Son; and as descending on the apostles, Holy Ghost.

NOLANA, in botany, a genus of plants, whose flower is monopetalous, campanulated, plicated, and spreading open: it hath five subulated filaments, topped with arrow-shaped antheræ. The seeds are five in number, of a roundish figure, and placed on a receptacle.

NOLI ME TANGERE, *touch me not*, in medicine, a malignant eruption in the face, occasioned by an extremely sharp corrosive humour; thus called, either because it affects those who touch it, or because the more it is touched, the worse it grows, and the farther it spreads.

NOMBRIL POINT, in heraldry, is the next below the fess-point, or the very center of the escutcheon. See POINT.

Supposing the escutcheon divided into two equal parts below the fess, the first of these divisions is the nombril, and the lower the base.

NOME, or NAME, in algebra, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binominal, trinominal, or the like.

NOMINALS, or NOMINALISTS, a sect of school-philosophers, the disciples and followers of Occam, or Ockham, an English cordelier, in the fourteenth century. They were great dealers in words, whence they were denominated word-sellers; but had the denomination of nominalists, because that, in opposition to the realists, they maintained, that words, and not things, were the object of dialectics.

**NOMINATIVE**, in grammar, the first case of nouns, which are declinable. See the articles **CASE** and **NOUN**.

**NONAGESIMAL**, in astronomy, the 90th degree of the ecliptic, reckoned from the eastern term or point. See the article **ECLIPTIC**, &c.

**NON-ABILITY**, in law, incapacity, or an exception taken against a plaintiff, in a cause, on some just ground, why he cannot commence a suit in law; as his being attainted of felony, outlawry, &c.

**NON-AGE**, in law, generally signifies all the time a person continues under the age of one and twenty; but in a special sense it is all the time a person is under the age of fourteen.

**NON COMPOS MENTIS**, in law, is used to denote a person's not being of sound memory and understanding. Of these persons there are four different kinds, an idiot, a madman, a lunatic who has lucid intervals, and a drunkard who deprives himself of reason by his own act and deed. In all these cases, except the last, one that is non compos mentis shall not lose his life for felony or murder; but the drunkard can have no indulgence on account of the loss of his reason, for, in the eye of the law, his drunkenness does not extenuate, but aggravate his offence.

**NON-NATURALS**, in medicine, so called, because by their abuse they become the cause of disease. See **DISEASE**.

Physicians have divided the non-naturals into six classes, viz. the air, meats and drinks, sleep and watching, motion and rest, the passions of the mind, the retentions and excretions.

**NON-RESIDENCE** is particularly applied to spiritual persons, who wilfully absent themselves for the space of one month, or two months at different times of the year, from their benefices; for which they are liable to penalties, by the statute of non-residence: but bishops, the king's chaplains, &c. are excepted.

**NON-SUIT**, signifies the dropping of a suit or action, or a renouncing thereof by the plaintiff or defendant, which happens most commonly upon the discovery of some error in the plaintiff's proceedings, when the cause is so far proceeded in, that the jury is ready at the bar to deliver in their verdict.

A non-suit, it is said, may be in the following cases, viz. where a person brings a personal action, and does not prosecute it with effect; or if, upon the trial, he refuses to stand a verdict, then he becomes non-suited; so where the plaintiff is not ready for trial at the calling and swearing of the jury, it is presumed he does not stand to proceed in his cause, and on that account the court may call him non-suited. Likewise, on a trial, when the jury comes in to deliver their verdict, and when the plaintiff is called on, to hear the same, in that case,

if he does not appear after being thrice called by the crier of the court, he is non-suited; which non-suit is to be recorded by the secondary, by the direction of the court: but if he afterwards appears, before the non-suit is actually recorded, the court may take the verdict; for that is not a non-suit, till it be recorded, upon motion made by the counsel for this purpose; and then it is a part of the record, in the nature of a judgment against the plaintiff.

**NONCONFORMISTS**, the same with dissenters. See the article **DISSENTERS**.

**NONE**, one of the seven canonical hours in the Romish church, answering to three o'clock in the afternoon.

**NONES**, *Nonæ*, in the Roman calendar, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October.

March, May, July, and October, had six days in their nones; because these alone, in the ancient constitution of the year by Numa, had thirty-one days apiece, the rest having only twenty-nine, and February thirty; but when Cæsar reformed the year, and made other months contain thirty-one days, he did not allot them six days of nones.

**NORMAL**, in geometry, signifies the same with a perpendicular, and is used for a line or plane that intersects another perpendicularly.

**NORROY**, the title of the third of the three kings at arms. See **HERALD**.

**NORTH**, in cosmography, one of the four cardinal points. See **COMPASS**.

**NORTHING**, in navigation, the latitude made by a ship, in sailing towards the north-pole.

**NOSE**, *Nasus*, in anatomy, the primary organ of smelling.

This varies greatly in size and figure in different subjects: anatomists divide its parts into external and internal; those most obvious are the dorsum or ridge, which runs along its whole length, one part of which is more prominent than the rest, and called the spine; the orbiculus, or extreme part, which in many is turned round; the alæ or pinnae, which are the sides; and the septum, which divides the nose into two parts, called nares or nostrils; the hairs also are of this number; these serve to hinder the mucous of the nostrils from continually running out, and to prevent insects and extraneous substances of many kinds from getting in. To these may be added, the common teguments, viz. the epidermis, the fat, and the cutis. The upper part of the nose is rigid, and composed of bones; the lower part is composed of a number of cartilages, muscles, and membranes.

The internal parts of the nose are the bones; as the ossa nasi, the maxillaria, the os cribriforme, the ossa spongiosa, the os frontale, the lachrymalia, the os palati, the vomer, and the os sphenoides. The

cartilages, which form the lower part, are connected by membranes, in order to render it flexible; the first of these form the anterior part of the septum narium; there are two very large and conspicuous ones in each of the alæ, and between these there are placed sometimes two, sometimes three, and sometimes more smaller ones; the septum narium is cartilaginous in its anterior and lower part; in its posterior and upper, it is bony: and these parts are surrounded by robust and strong membranes, which join them firmly together.

**NOSTRILS**, *Nares*, in anatomy, the two apertures or cavities of the nose, through which the air passes, and which serve to convey odours, and to carry off the pituita separated in the sinuses of the base of the cranium. See **NOSE**.

**NOTARY**, *Notarius*, signifies a person, usually some scrivener, who takes notes, or frames short draughts, of contracts, obligations, charter-parties, or other writings. At present we call him a notary-public, who publicly attests deeds, or writings, in order to make them authentic in another nation: but he is principally employed in business concerning merchants, as making protests of bills of exchange, &c. And noting a bill, is where he goes to take notice of a merchant's refusal to accept or pay the same.

**NOTATION**, in arithmetic and algebra, the method of expressing numbers or quantities by signs or characters, appropriated for that purpose.

**NOTE**, *nota*, is used for a character or abbreviation, serving to denote or express something in a little compass.

**NOTES**, in music, characters which mark the sounds, i. e. the elevations and fallings of the voice, and the swiftness and slowness of its motions. See **CHARACTER**.

**NOTE** is likewise used for a mark made in a book or writing where there occurs something remarkable and worthy of particular notice: as also for an observation or explication of some passage in an author added in the margin, at the bottom of the page, or elsewhere, by an editor, in which sense it stands contradistinguished to text.

**NOTE** is also a minute, or short writing, concerning some article of business, in which sense we say, promissory note, note of hand, bank note, &c.

*To NOTE a Bill.* See the article **BILL**.

**NOTE of a Fine**, in law, an abstract of the fine or contract made by the chirographer, before the same is engrossed.

**NOTICE**, in law, is defined to be the making of something known, which a man might be ignorant of before: and it has divers effects in our law; for thereby a party giving the same, may reap a benefit which he otherwise should not have had; and by this means the person to whom it is given, is liable to some charge or action to which without it he had not been subject.

**NOTION**, in logic, an idea or representation of any thing in the mind. See the article **IDEA**.

**NOVATIONS**, a Christian sect which sprang up in the third century, so called from Novatian, a priest of Rome, or Novatus, an African bishop, who separated from the communion of pope Cornelius, whom Novatian charged with a criminal lenity towards those who had apostatized during the persecution of Decius. He denied the church's power of remitting mortal sins, upon the offender's repentance; and at last went so far as to deny that the apostles could ever hope for pardon even from God himself. Novatus coming to Rome, joined with the followers of Novation, and added to these doctrines another, which was the unlawfulness of second marriages, against which this became as severe as against apostates; denying communion to such as married a second time after baptism, and treating widows who married again, as adulteresses. The two leaders were proscribed and declared heretics, not for excluding penitents from communion, but for denying that the church had the power of remitting sins.

**NOVEL**, in the civil law, a term used for the constitutions of several emperors, as of Justin, Tiberius, Leo, and more particularly of those of Justinian.

**NOVEL**, in matters of literature, a fictitious history of a series of surprizing and entertaining events in common life, wherein the rules of probability are, or ought to be, strictly preserved; in which it differs from a romance, where the hero and heroine is some prince and princess, and the events which lead to the catastrophe, are in general highly absurd and unnatural. The best novels are those which by means of a well told story, convey a number of noble and elevated sentiments, and instruct the reader in the knowledge of mankind.

**NOVEMBER**, in chronology, the eleventh month of the Julian year, consisting only of thirty days: it got the name of November, as being the ninth month of Romulus's year, which began with March.

**NOVEMSILES**, or **NOVENSILES DII**, in Roman antiquity, certain gods brought to Rome by the Sabines, and so called as being nine in number, viz. Lara, Vesta, Minerva, Feronia, Concord, Fidelity, Fortune, Chance, Health.

Some understand, by novensiles dii, new created gods, or those whose worship was brought from some foreign country to Rome; whilst others pretend, they signified the nine muses.

**NOUN**, *Nomen*, in grammar, a part of speech, which signifies things without any relation to time; as a man, a house, sweet, bitter, &c.

**NOURISHMENT**, or **NUTRITION**, in physiology. See **NUTRITION**.

**NOWED**, in heraldry, signifies knotted, from the Latin *nodatus*; being applied to the tails of such

# NUM

creatures as are very long, and sometime represented in coat armour, as if tied up in a knot.

**NUCLEUS**, in general, denotes the kernel of a nut, or even any seed inclosed within a husk.

The term nucleus is, also used for the body of a comet, otherwise called its head. See the article **COMET**.

**NUDITES**, in painting and sculpture, denotes those parts of an human figure which are not covered with any drapery; or those parts where the carnation appears.

**NUMBER**, *Numerus*, in arithmetic, an assemblage of several units, or things of the same kind.

**NUMBERS**, in poetry, oratory, music, &c. are certain measures, proportions, or cadences, which render a verse, period, or song, agreeable to the ear. See **METRE**.

*Book of NUMBERS*, the fourth book of the Pentateuch, taking its denomination from it numbering the families of Israel.

A great part of this book is historical, relating to several remarkable passages in the Israelites march through the wilderness. It contains a distinct relation of their several movements from one place to

# NUM

another, or the two and forty stages through the wilderness, and many other things, whereby we are instructed and confirmed in some of the weightiest truths that have immediate reference to God and his providence in the world. But the greatest part of this book is spent in enumerating these laws and ordinances, whether civil or ceremonial, which were given by God, but not mentioned before in the preceding books.

**NUMB-FISH**, the same with the torpedo or cramp-fish. See the article **TORPEDO**.

**MUMERAL LETTERS**, those letters of the alphabet which are generally used for figures, as I, V, X, L, C, D, M. See the article **NUMERATION**.

**NUMERAL CHARACTERS**. See the article **CHARACTER**.

**NUMERALS**, in grammar, those words which express numbers; as 6, 8, 10, &c.

**NUMERATION**, or **NOTATION**, in arithmetic, the art of expressing in characters any number proposed in words; or of expressing in words any number proposed in characters.

The characters used to express numbers by, are either the ten numeral figures of the Arabians, viz.

one, two, three, four, five, six, seven, eight, nine, cypher;  
I 2 3 4 5 6 7 8 9 0

Or the seven numeral letters of the Romans,

one, five, ten, fifty, hundred, five-hundred, thousand.  
I V X L C D M

Each of which figures, besides their own single value, receives several denominations according to their place and order. A number has so many places as there are figures in it, as 36487 is the number of five places. The order in whose number is from the right to the left. The value of places decrease

in a decuple proportion: for every place to the left is ten times the value of the next place to the right. Each place also has its name; and those names, for the more easy reading of large numbers, are distinguished by periods, half-periods, &c.

For as a place } is { ten } times the value  
So a half-period } { a thousand } of that before it.  
And a period } { a million }

A cypher is of itself insignificant; but by its place alters the value of the subsequent figure: and, since

the value of each place is ten times the value of the next before it, it is certain

that { I } in the first { 10 } in the { 100 } in the { 1000 } in the  
2 } place, is { 20 } second, { 200 } third, { 2000 } fourth,  
3 } { 30 } { 300 } { 3000 } &c.  
&c. { &c. }

The value of each figure in any rank of numbers, how large soever, is readily found by the following rule:

Begin at units, set a point under the seventh

place; then reckoning that as one, count forwards, and set another under the next seventh place, so continue to the end.

then

Then the { first  
second  
third  
fourth, &c. } point from units  
stands under { millions,  
billions,  
trillions,  
quadrillions, &c.

As is evident in the following example :

| Periods      | Quadril. |   |   |       |   |   | Trillions |   |       |   | Billions |   |       |   | Millions |   |       |   | Units |   |       |   |   |   |   |   |   |   |   |   |
|--------------|----------|---|---|-------|---|---|-----------|---|-------|---|----------|---|-------|---|----------|---|-------|---|-------|---|-------|---|---|---|---|---|---|---|---|---|
| Half-periods | th.      |   |   | units |   |   | th.       |   | units |   | th.      |   | units |   | th.      |   | units |   | th.   |   | units |   |   |   |   |   |   |   |   |   |
| Degrees      | c        | x | u | c     | x | u | c         | x | u     | c | x        | c | x     | u | c        | x | c     | x | u     | c | x     | u |   |   |   |   |   |   |   |   |
| Figures      | 1        | 2 | 3 | 4     | 5 | 6 | 7         | 8 | 9     | 0 | 9        | 8 | 7     | 6 | 5        | 4 | 3     | 2 | 1     | 0 | 1     | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 1 |

By this means you may have as clear a notion of, and may as easily read a number of seventy places as of seven.

**NUMERATOR** of a *Fraction*. See the article **FRACTION**.

**NUN**, a woman; in several Christian countries, who devotes herself, in a cloister or nunnery, to a religious life.

**NUNCIO**, or **NUNTIO**, an ambassador from the pope to some catholic prince or state, or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors.

**NUNCUPATIVE**, in the schools, something that is only nominal, or has no existence but in name.

**NUNCUPATIVE WILL**, denotes a last will or testament, only made verbally, and not put in writing. See the articles **WILL** and **TESTAMENT**.

**NUPTIAL RITES**, the ceremonies attending the solemnization of marriage. See the article **MARRIAGE**.

**NURSERY**, in gardening, is a piece of land set apart for raising and propagating all sorts of trees and plants, to supply the garden and other plantations.

In a nursery for fruit-trees, the following rules are to be observed: 1. That the soil should not be better than that in which the trees are to be planted out for good. 2. That it ought to be fresh, and not such as has been already worn out by trees, or other large-growing plants. 3. It ought neither to be too wet nor too dry, but rather of a middling nature; though, of the two extremes, dry is to be preferred; because, though trees in such a soil do not make so great a progress yet they are generally sounder, and more disposed to fruitfulness. 4. It must be inclosed in such a manner, that neither cattle nor vermin may come in; and so as particularly to exclude hares and rabbits, which, when the ground is covered with snow, are great destroyers of young trees. 5. The ground being inclosed should be carefully trenched about two feet deep; this should be done in August, that it may be ready for receiving young stocks at the season for planting,

which is commonly about the beginning of October: in trenching the ground, you must be careful to cleanse it from the roots of all noxious weeds.

6. The season being come for planting, level down the trenches as equal as possible; and then lay out the ground into quarters, which may be laid out in beds for a seminary, in which you may sow the seeds or stones of fruit. 7. And having provided yourself with stocks, the next year proceed to transplant them, in the following manner: draw a line across the ground intended to be planted, and open a number of trenches exactly straight; then take the stocks out of the seed-beds; in doing which, you should raise the ground with a spade, in order to preserve the roots as entire as possible; prune off the very small fibres, and if there are any that have a tendency to root directly downwards, such roots should be shortened: then plant them in the trenches, if they are designed for standards, in rows three feet and a half, or four feet, from each other, and a foot and a half distant in the rows; but if for dwarfs, three feet, row from row, and one foot in the row, will be a sufficient distance. These plants should by no means be headed, or pruned at top, which will weaken them, and cause them to produce lateral branches.

If the winter should prove very cold, lay some mulch on the surface of the ground near their roots, taking care not to let it lie too thick near the stems of the plants, and to remove it as soon as the frost is over. In the summer season, destroy the weeds, and dig up the ground every spring between the rows.

The second year after planting, such of the stocks as are designed for dwarfs will be fit to bud; but those that are designed for standards should be suffered to grow five or six feet high before they are budded or grafted; for the manner of doing which, see the articles **INOCULATION** and **GRAFTING**.

As to timber-trees, Mr. Miller advises those gentlemen who would have plantations in parks, woods, &c. to make nurseries upon the ground intended for planting, where a sufficient number of the

the trees may be left standing, after the others have been drawn out to plant in other places.

The ground intended for the flower nursery should be well situated to the sun; and defended from strong winds by plantations of trees or buildings. The soil also should be light and dry, especially for bulbous-rooted flowers; for in this nursery, the off-sets of all bulbous-rooted flowers should be planted, and remain there till they become blowing roots, when they should be removed into the pleasure-garden, and planted either in beds or borders, according to the goodness of the flowers. These flowers may also be raised in the nursery from seeds.

The seedling auriculas, polyanthoses, ranunculuses, anemonies, carnations, &c. should be raised in this nursery, where they should be preserved till they have flowered, when all those should be marked that are worthy of being transplanted into the flower-garden; this should be done in their proper seasons: for all these seedling flowers ought not indiscriminately to be exposed to public view in the pleasure-garden, because it always happens, that there are great numbers of ordinary flowers produced among them, which will there make but an indifferent appearance.

**NUSANCE**, in law, a thing done to the annoyance of another.

**NUT**, *Nux*, among botanists, denotes a pericarpium of an extraordinary hardness, inclosing a kernel or seed; of which there are several kinds, as filberts, walnuts, &c. See the articles **FILBERT**, **WALNUT**, &c.

The word nut makes part of the English names of several plants; as the bladder-nut, or staphylæa; the chocolate-nut, or theobroma; the cob-nut, or corylus; the earth-nut, or buniun; the physic-nut, or croton, &c. See the articles **STAPHYLÆA**, &c.

**NUTATION**, in astronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position. See the articles **EARTH** and **INCLINATION**.

Sir Isaac Newton observes, that the moon has the like motion, only very small, and scarce sensible.

**NUTMEG**, the kernel of a large fruit of a tree, which grows naturally in the East-Indian islands: it is called by botanists *Myristica*; but the description of the flower, and the class it belongs to, is not yet properly ascertained, the plants which produce this fruit being entirely in the possession of the Dutch, which they carefully keep to themselves.

The nutmeg is separated from its investient coat, the mace, before it is sent over to us; except that the whole fruit is sometimes imported in preserve, by way of sweetmeat, or as a curiosity. See the article **MACE**.

There are two kinds of nutmeg in the shops, the one called by authors the male, and the other the

female. The female is the kind in common use, and is of the shape of an olive: the male is long and cylindric, and has less of the fine aromatic flavour than the other, so that it is much less esteemed, and people who trade largely in nutmegs will seldom buy it. Besides this oblong kind of nutmegs, there are others of irregular figures, but mere *lusus naturæ*, not owing to a different species of the tree. The longer male nutmeg, as we term it, is called by the Dutch the wild nutmeg. It is always distinguishable from the others, as well by its want of fragrantcy, as by its shape: it is very subject to be worm-eaten, and is strictly forbid by the Dutch to be packed up among the other, because it will give occasion to their being worm-eaten too, by the insects getting from it into them, and breeding in all parts of the parcel.

The largest, heaviest, and most unctuous of the nutmegs are to be chosen, such as are of the shape of an olive, and of the most fragrant smell. The Dutch import them from the East-Indies.

Nutmeg is greatly used in our foods, and is of excellent virtues as a medicine; it is a good stomachic, it promotes digestion, and strengthens the stomach. It also stops vomiting; is an excellent remedy in flatulences; and is happily joined with rhubarb, and other medicines, in diarrhœas. It is observed to have a soporific virtue, and to exert it too strongly, if taken in immoderate quantities. It has a considerable degree of astringency; and given after toasting before the fire, till thoroughly dry and crumbly, it has been sometimes known alone to cure diarrhœas.

**NUTRITION**, in the animal œconomy, is the repairing the continual loss, which the different parts of the body undergo.

The motion of the parts of the body, the friction of these parts with each other, and especially the action of the air, would destroy the body entirely, if the loss was not repaired by a proper diet, containing nutritive juices; which being digested in the stomach, and afterwards converted into chyle, mix with the blood, and are distributed through the whole body for its nutrition.

**NUX MOSCHATA**. See **NUTMEG**.

**NUX PISTACHIA**. See **PISTACHIA**.

**NYCHTHEMERON**, *νυκθημερον*, the natural day, or day and night, which together, always make twenty-four hours. See the articles **DAY** and **NIGHT**.

**NYCTALOPÆA**, in medicine, a two-fold disorder of the eye, one of which is opposite to the other. In the first, the sight is best in the night, and in obscure places; whereas, in a clear light, their sight fails, so that they can hardly see any thing. In the other sort of *nyctalopæa*, the patient can see nothing at all except in a clear and bright light.

As these infirmities arise from a natural bad formation of the eye, they are therefore incurable.

**NYCTANTHES**, Arabian-jasmine, in botany, a genus of plants, whose flower is monopetalous and faucer-shaped, divided at the top into eight oblong segments: the stamina are two subulated filaments, topped with erect antheræ: the fruit is a roundish berry, having two cells, each containing a large roundish seed.

**NYCTICORAX**, a bird of the heron-kind, called in English the night-raven, by reason it flies chiefly in the night-time, and makes a very disagreeable croaking.

**NYMPH**, in mythology, an appellation given to certain inferior goddesses inhabiting the mountains, woods, waters, &c. said to be the daughters of Oceanus and Tethys.

**NYMPH**, among naturalists, that state of winged insects, between their living in the form of a worm, and their appearing in the winged or most perfect state.

The eggs of insects are first hatched into a kind of worms, or maggots; which afterwards pass into the nymph-state, surrounded with shells or cases of their own skins; so that, in reality, these nymphs are only the embryo-insects, wrapped up in this covering; from which they at last get loose, though not without great difficulty.

During the nymph-state, the creature loses its motion. Swammerdam calls it *nympha aurelia*, or simply *aurelia*; and others give it the name of *chrysalis*, a term of the like import. See the article **CHRYSLIS**.

**NYMPHÆ**, in anatomy, two membranaceous parts, situated on each side the rima.

They are of a red colour and cavernous structure, somewhat resembling the wattles under a cock's throat. They are sometimes smaller, sometimes larger, and are continuous to the præputium of the clitoris, and joined to the interior side of the labia.

**NYMPHÆA**, the water-lily, in botany, a genus of plants, the flower of which consists of a number of petals, usually fifteen; they are smaller than the cup, and are inserted into the side of the germen in more than a single series: the fruit is an oval fleshy berry, containing a great many roundish seeds.

The root of this plant was recommended by the ancients as an astringent for internal use, and as a styptic to stop the bleeding of wounds, or other hæmorrhages.

**NYMPHEUM**, in antiquity, a public hall, magnificently decorated, for entertainment, &c. and where those, who wanted convenience at home, held their marriage feasts; whence the name.

**NYMPHOMANIA**, in medicine the same with *furor uterinus*. See **FUROR**.

**NYMPHOTOMIA**, in surgery, the operation of cutting the nymphæ, when too large. See the article **NYMPHÆ**.

**NYSSA**, in botany, a genus of plants, producing male and hermaphrodite flowers; they are both destitute of a corolla; but the cup is divided into five segments, and spreads open: the fruit is an ovate unilocular drupe, containing an oval acute nut.

# O.

## O A K

**O** The fourteenth letter, and fourth vowel of our alphabet, pronounced as in the words *nose, rose, &c.*

The sound of this letter is often so soft, as to require it double, and that chiefly in the middle of words; as *goose, proof, &c.* and in some words this *oo* is pronounced like *u* short, as in *flood, blood, &c.*

As a numeral, *O* is sometimes used for eleven; and with a dash over it, thus *Ō*, for eleven thousand.

**OAK-TREE**, *Quercus*, in botany, a genus of plants, producing male and female flowers; the male are disposed in a loose amentum, each having a monophyllous cup, divided into four or five segments; there is no corolla, but several very short filaments topped with large twin antheræ: the cup of the female flower is formed of a single, rough, coriaceous, hemispherical leaf, undivided at the edge; the germen is ovate and small; the style is five-pointed and longer than the cup, and the stigmata are single and persistent: the fruit is an oval nut (commonly called an acorn) covered with a coriaceous substance, the base of it being placed in the cup.

There are several species of oak, but the sort which is most commonly known, grows naturally in England in many places. It is said, that an oak-tree is an hundred years coming to its full growth, an hundred in perfection, and an hundred years decaying.

The great advantages arising from plantations of this tree, is so well known to the nation, that it is scarce necessary to inform the reader of its great use in civil and, particularly, naval architecture, there being no timber in the world so good for ship-building as the English oak, which makes our formidable fleets as much superior in the strength of their parts and for durability, as our seamen are in skill and courage to those of other nations.

The bark of the oak-tree is of very great service in tanning leather, and its acorns are excellent food for hogs.

## O A K

The excellency of this noble plant is so-universally known, that to offer any thing in order to encourage its greater increase, would be needless, seeing that all our gentlemen of fortune are not only judges of its great use, but at this time are principally devoted to the pleasures and profit of planting in general, wherein the oak has a place not inferior to any.

This advantageous plant is raised from the acorn, which should be sown immediately after its falling from the tree, which is about the beginning of November; and is always best when the acorn is planted in the place appointed for its future growth: but when it cannot be so ordered, they must be sown in a seed-bed, at about two or three inches asunder in the rows, and nine or ten inches row from row. In the spring, the plants will appear, when they must be kept clear from weeds; and the following October they may be transplanted in rows three feet asunder, and eighteen inches in the rows, observing not to suffer the plants to abide long out of the ground at the time of transplanting; here they may remain for three or four years, at which time they will be large enough to be transplanted where they are intended to remain for good: the season for this work is in autumn, at which time, if they are carefully taken up, there will be little danger of their succeeding, but the heads should by no means be shortened, which is too much practised; all that should be done, is only to cut off any bruised or ill-placed branches, which should be taken off close to the place where they are produced.

The soil in which the oak-tree makes the greatest progress, is a deep rich loam, in which it grows to the largest size; and the timber of those trees which grow upon this land, is generally more pliable than that which grows on a shallow or drier ground, but the wood of the latter is much more compact and hard. Indeed, there are few soils in England in which the oak will not grow, provided there is proper care taken in their cultivation, though this tree will not thrive equally in all soils; but yet it might be cultivated to a national advantage, upon many large

large wastes in several parts of England, as also to the great profit of the estates where these tracts of land now lie uncultivated and produce nothing to the owner.

The proper distance that oaks should be planted from each other, in woods, groves, parks, &c. should not be less than thirty feet.

There are a great number of trees that go under the name of oak in divers parts of the world, but there is no where so many different kinds as in America, though the wood is not near so valuable as the English oak.

In times of scarcity, a great many poor people have made bread of the acorns; and the poets tell us, they were the food of the golden-age: however, they are heavy, windy, and hard to digest; therefore mankind, in those early ages, must doubtless have had a better digestion than us.

The leaves of the oak are styptic, a little bitterish, and all parts of it are astringent; they have often been prescribed in all sorts of hæmorrhages and fluxes of the belly.

*OAK of Jerusalem*, in botany. See the article CHENOPODIUM.

*Poison-OAK*. See TOXICODENDRUM.

*OAKAM*, old ropes untwisted, and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

*OAR*, in navigation, a long piece of wood, made round where it is to be held in the hand, and thin and broad at the other end, for the easier cutting and resisting the water, and consequently moving the vessel, by rowing.

Oars for ships are generally cut out of fir-timber, those for barges are made out of New-England or Dantzic rafters, and those for boats, either out of English ash, or fir-rafters from Norway. See the article ROWING.

*OAT*, *Avena*, in botany, a genus of plants, whose flowers grow in loose particles; the cup is a bivalvular glume; the corolla consists of two valves, the lower one being of the same size with the cup, putting out from the back a spiral awn or beard, which is jointed and reflexed: the stamina are three capillary filaments, topped with oblong forked antheræ: the corolla serves as a pericarpium, surrounding a single seed, which is oblong and swelling, pointed at each end, having a longitudinal furrow, and shut up in the chaff.

There are three sorts of oats cultivated in England, viz. the common or white oat, the black oat, and the brown or red oat; the first sort is more common about London, the second in the northern parts, and the red oats are cultivated in Derbyshire, Staffordshire, and Cheshire, and are a very hardy sort.

Oats are a very profitable grain, and absolutely necessary, being the principal grain which horses

love, and are esteemed the most wholesome food for those useful animals, it being sweet and of an opening nature, other grains being apt to bind, which is injurious to labouring horses.

Oats will thrive on cold barren soils which will produce no other sort of grain, it will also grow on the hottest land; in short, there is no land too rich or too poor for it, too hot or too cold, but it will grow on it; and in wet harvests, when other grain is spoiled, this will receive but little or no damage; the straw and husks being of so dry a nature, that if they are housed wet, they will not heat in the mow and become mouldy, as other grain usually do.

The season for sowing oats is in February or March, according to the nature of the land, and as the season is early or late.

The meal of this grain makes tolerable good bread, and is the common food of the country people in the north; and in the south, it is esteemed for pottage and other uses. Those who feed upon it, are generally very healthy, which is a sign that it yields good nourishment. Oatmeal blunts the acrimony of the humours, is cooling, and carries off acrimoneous salts by the urinary passages: flummery with milk, is used by many as a cooling diet in hot weather; and water-gruel is every where known for its inoffensive properties.

*OATH*, *Jusjurandum*, is a solemn affirmation, in which the persons sworn invoke the Almighty to witness that their testimony is true, renouncing all claim to his mercy, and calling for his vengeance if it be false; on which account such an oath is termed sacramentum, a holy band, or tie; and it is also called a corporal oath, because the person who takes it, lays his right-hand on the book of the Evangelists.

All oaths must be administered by a person duly authorized, and in order to discover truth and right; and therefore, if a person not duly authorized, administers an oath, he is punishable both with fine and imprisonment.

A person who is to be a witness in a cause, may have two oaths administered to him; the one to speak the truth, in relation to what the court shall think fit to ask him, concerning himself or any thing else that is not evidence in the cause; and the other purely to give evidence in the cause wherein he is produced as a witness; the former of which is called an oath upon a voyer dire.

By statute, all that bear offices of any kind under the government, members of the house of commons, ecclesiastical persons, members of colleges, schoolmasters, serjeants at law, counsellors, attornies, solicitors, advocates, proctors, &c. are required to take the oath of allegiance, supremacy, and abjuration; all persons neglecting, or refusing, to take these oaths, are declared to be incapable of executing their offices and employments, of suing at law,

of being guardians, executors, &c. and are liable to the forfeiture of 500*l.* 13 W. III. c. 6. 1 Ann. c. 22. and 1 Geo. I. c. 13.

**OBADIAH**, or *the Prophecy of OBADIAH*, a canonical book of the Old Testament, which is contained in one single chapter, and is partly an invective against the cruelty of the Edomites, who mocked and derided the children of Israel, as they passed into captivity, and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil among themselves: and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

**OBEDIENCE**, or **OBEDIENTIA**, in the canon law, is sometimes used for an office, or the administration of it. In our antient customs obedientia was used, in the general, for every thing that was enjoined the monks by the abbots: and in a more limited sense it was applied to the farm belonging to the abbey, to which the monks were sent *vi ejusdem obedientiæ*, either to look after the farm, or collect the rents. Hence, these rents themselves were also called obedientiæ.

**OBELISCOTHECA**, in botany, a name given to the rudbeckia of Linnæus. See the article **RUDBECKIA**.

**OBELISK**, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

**OBELISK**, †, in grammar, a mark in form of a dagger, used to refer the reader to a note in the margin, at the side or bottom of a page.

**OBJECT**, in philosophy, something apprehended, or presented to the mind, by sensation or by imagination.

Chauvinus defines an object to be that about which a power, act, or habit is employed: thus, good is the object of the will, truth of the understanding; and, in like manner, colour is the object of sight, sound of hearing, &c.

**OBJECT GLASS** of a *Telescope*, or *Microscope*, the glass placed at the end of the tube which is next the object. See the articles **TELESCOPE** and **MICROSCOPE**.

**OBJECTION**, something urged to overthrow a position, or a difficulty raised against an allegation, or proposition of a person we are disputing withal.

**OBJECTIVE** is used, in the schools, in speaking of a thing which exists no otherwise, than as an object known. The existence of such a thing is said to be objective.

This word is also used for the power, or faculty, by which any thing becomes intelligible; and for the act itself, whereby any thing is presented to the mind and known.

**OBIT**, among Christians, a funeral solemnity,

or office for the dead, most commonly performed when the corpse lies in the church uninterred.

It likewise signifies the anniversary office, or annual commemoration of the dead, performed yearly on the day of their death, with prayers, alms, &c. In religious houses they have a register, in which they enter the obits of their founders, or benefactors, which is thence termed the obituary.

**OBLATI**, in church-history, were secular persons, who devoted themselves and their estates to some monastery, into which they were admitted as a kind of lay-brothers. The form of their admission was, putting the bell-ropes of the church round their necks, as a mark of servitude. They wore a religious habit, but differed from that of the monks.

**OBLATION**, a sacrifice, or offering made to God. See **SACRIFICE**.

**OBLIGATION**, in general, denotes any act whereby a person becomes bound to another, to do something; as to pay a sum of money, be surety, or the like.

Obligations are of three kinds, viz. natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligations, on civil authority alone, without any foundation in natural equity; and mixed obligations are those which being founded on natural equity, are farther enforced by civil authority.

**OBLIQUE**, in geometry, something aslant, or that deviates from the perpendicular. Thus an oblique angle, is either an acute or obtuse one, *i. e.* any angle except a right one. See **ANGLE**.

**OBLIQUE ASCENSION**, in astronomy. See the article **ASCENSION**.

**OBLIQUE CASES**, in grammar, are all the cases except the nominative. See **CASE**.

**OBLIQUE DESCENSION**, in astronomy. See the article **DESCENSION**.

**OBLIQUE LINE**, that which, falling on another line, makes oblique angles with it, viz. one acute, and the other obtuse.

**OBLIQUE PERCUSSION**, in mechanics. See the article **PERCUSSION**.

**OBLIQUE PLANES**, in dialling, are those which recline from the zenith, or incline towards the horizon. See the articles **DIAL** and **PLANE**.

The obliquity, or quantity of this inclination, or reclination, may be found by means of a quadrant.

**OBLIQUE SAILING**, in navigation, is when a ship sails upon some rhumb between the four cardinal points, making an oblique angle with the meridian; in which case, she continually changes both latitude and longitude.

Oblique sailing is of three kinds, viz. plain-sailing, Mercator's sailing, and great circle-sailing. See the article **NAVIGATION**.

**OBLIQUE SPHERE**, is where the pole is elevated any number of degrees less than 90°; in

which case, the axis of the world, the equator, and parallels of declination will cut the horizon obliquely. See the article SPHERE.

**OBLIQUITY** of the *Ecliptic*. See the article ECLIPTIC.

**OBLIQUUS**, in anatomy, oblique, a name given to several muscles, particularly in the head, eyes, and abdomen. See **FRONTAL MUSCLES**.

**OBLONG**, in general, denotes a figure that is longer than broad: such is a parallelogram, ellipsis, &c. See the articles PARALLELOGRAM and ELLIPSIS.

**OBLONGATA MEDULLA**, in anatomy. See **MEDULLA** and **BRAIN**.

**OBOLARIA**, in botany, a genus of plants, whose flower is monopetalous and unequal; the tube is campanulated and ventricose, and the limb divided into four segments; it hath four awl-shaped stamina, two of which are larger than the others. The fruit is an oval, compressed, ventricose capsule, formed of two valves, containing a great number of seeds in form of very fine powder.

**OBOLUS**, in antiquity, an antient Athenian coin.

**OBSCURE**, something that is dark and reflects little light, or that is not clear and intelligible.

Obscurity, in this last sense, arises from hence, that we do not conceive and express things as they are, but as we judge them to be, before we have fully examined them.

**OBSCURO**, or **CLARO-OBSCURO**. See **CLARO-OBSCURO**.

**OBSEQUIES**, the same with funeral solemnities. See the articles **BURIAL**, **FUNERAL**, &c.

**OBSERVANCE**, in a monastic sense, denotes a community of religious, tied to the perpetual observation of the same rule.

**OBSERVATION**, among navigators, signifies the taking the sun's, or a star's meridian altitude, in order thereby to find the latitude. See **LATITUDE**.

*Cælestial* **OBSERVATIONS**. See **COELESTIAL**.

**OBSERVATORY**, a place destined for observing the heavenly bodies; being, generally, a building erected on some eminence, covered with a terrace for making astronomical observations.

**OBSIDIONALIS**, an epithet applied by the Romans to a sort of crown. See the article **CROWN**.

**OBSTRUCTION**, in medicine, such an obturation of the vessels, as prevents the circulation of the fluids, whether of the sound and vital, or of the morbid and peccant kind, through them; arising from an excess of the bulk of the fluid to be transmitted, above the capacity of the vessel which ought to transmit it.

**OBTURATOR**, in anatomy, a name for the two muscles of the thigh, one of which is the marsupialis, and is called obturator internus, and the other the obturator externus. These two muscles

shut up the foramen or aperture between the os pubis and the hip-bone. The obturator internus comes from the internal circumference of the hole that is between the ischium and the os pubis; and passing through the sinuosity of the ischium, it is inserted into the dent of the great trochanter. Its tendon lies between the gemini: it turns the thigh to the outside. The obturator externus comes from the external circumference of the same hole as the former; it embraces the neck of the thigh-bone, and passes under the quadratus to the small cavity of the great trochanter.

**OBTUSE**, signifies blunt, dull, &c. in opposition to acute, sharp, &c. thus we say obtuse angle, obtuse angled triangle, &c. See the article **ANGLE**, &c.

**OCCATION**, a term in the antient husbandry, by which they expressed what we do by harrowing, though they performed it with a different instrument; being a kind of rake, with the teeth of which they levelled the ground, and broke the clods; and with the hand strewed the corn over this level ground. Then they brought on the plough and ploughed it in, so that the grain was sown in furrows, as we express it, and usually came up as we see it does at this time with us in the same case in the lower parts only. After it got a few leaves they went over the ground again with the same instrument, to clear away the weeds, and move the earth about the roots of the young plants.

**OCCIDENT**, in geography, the westward quarter of the horizon, or that part of the horizon where the ecliptic, or the sun therein, descends into the lower hemisphere, in contradistinction to orient. Hence we use the word occidental, for any thing belonging to the west, as occidental bezoard, occidental pearl, &c.

**OCCULT**, something secret, hidden, or invisible. The occult sciences, are magic, necromancy, cabbala, &c.

**OCCULT**, in geometry, is used for a line that is scarce perceivable, drawn with the point of the compasses, or a leaden pencil. These lines are used in several operations, as the raising of plans, designs of building, pieces of perspective, &c. They are to be effaced when the work is finished.

**OCCULTATION**, in astronomy, the time a star or planet is hid from our sight, by the interposition of the body of the moon, or of some other planet. See the article **ECLIPSE**.

*Circle of perpetual* **OCCULTATION**, is a parallel in an oblique sphere, as far distant from the depressed pole, as the elevated pole is from the horizon. See the article **HORIZON**.

All the stars between this parallel and the depressed pole, never rise, but lie constantly hid under the horizon of the place.

**OCCUPANT**, in law, the person that first seizes, or gets possession of a thing; and this by law must

must be of what has a natural existence, as of land, &c.

**OCCUPATION**, in a legal sense, is taken for use or tenor, as in deeds it is frequently said, that such lands are, or lately were, in the tenure or occupation of such a person. This is likewise used for a trade or mystery.

**OCCUPATION**, or **OCCUPANCY**, in the civil law, denotes the possession of such things as at present properly belong to no private person; but are capable of being made so, as by seizing or taking of spoils in war, by catching things wild by nature, as birds and beasts of game, &c. or by finding things before undiscovered, or lost by their proper owners.

**OCEAN**, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands. The ocean is distinguished into three grand divisions. 1. The Atlantic ocean, which divides Europe and Africa from America, which is generally about three thousand miles wide. 2. The Pacific ocean, or South-sea, which divides America from Asia, and is generally about ten thousand miles over: and 3. The Indian Ocean, which separates the East-Indies from Africa, which is three thousand miles over. The other seas, which are called oceans, are only parts or branches of these, and usually receive their names from the countries they border upon.

**OCHNA**, in botany, a genus of plants, whose flower consists of five roundish petals; the filaments are numerous, short, and connivent, and topped with roundish antheræ. The fruit is a very large, truncated, and fleshy receptacle, containing on each side a single berry, with a single oval seed.

**OCHRE**, *Ochra*, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water.

Ochres are of various colours, as red, yellow, blue, brown, green, &c. Of the red there are eleven species, of the yellow as many, of blue one, of brown two, of green one, and of black two. All which have, at one time or other, been used in painting.

**OCIMUM**, basil, in botany. See the article **BASIL**.

**OCTAETERIDES**, in chronology, denotes a cycle of eight years, at the end of which, three entire lunar months were added.

This cycle was in use at Athens, till Meton discovered the golden number.

**OCTAGON**, or **OCTOGON**, in geometry, is a figure of eight sides and angles: and this, when all the sides and angles are equal, is called a regular octagon, or one which may be inscribed in a circle. If the radius of a circle circumscribing a regular

octagon be  $=r$ , and the sides of the octagon be  $=y$ ; then  $y = \sqrt{2r^2 - r\sqrt{2r^2}}$ .

**OCTAGON**, in fortification, denotes a place that has eight bastions. See the article **FORTIFICATION**.

**OCTAHEDRON**, or **OCTAEDRON**, in geometry, one of the five regular bodies, consisting of eight equal and equilateral triangles. See the article **SOLID**.

The square of the side of the octahedron is to the square of the diameter of the circumscribing sphere, as 1 to 2.

If the diameter of the sphere be 2, the solidity of the octahedron inscribed in it will be 1.33333, nearly.

The octahedron is two pyramids put together at their bases, therefore its solidity may be found by multiplying the quadrangular base of either of them, by one third of the perpendicular height of one of them, and then doubling the product.

**OCTANDRIA**, the name of the eighth class in the Linnæan system of botany: it comprehends all those plants whose flowers are hermaphrodite and furnished with eight stamina or male parts in each. To this class belong the Indian cress, knot-grass, tree-primrose, French willow, &c.

**OCTANT**, or **OCTILE**, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or  $45^\circ$  from each other.

**OCTOSTYLE**, in the ancient architecture, is the face of an edifice adorned with eight columns.

The eight columns of the octostyle may either be disposed in a right line, as in the Pantheon, and the pseudodiptere temple of Vitruvius; or in a circle, as in the round monothere temple of Apollo Pythius at Delphi, &c.

**OCULUS**, the eye, in anatomy. See the article **EYE**.

**ODE**, in poetry, a song, or a composition proper to be sung.

Among the antients, ode signified no more than songs; but with us they are very different things. The antient odes were generally composed in honour of their gods, as many of those of Pindar and Horace.

These had originally but one stanza, or strophe, but afterwards they were divided into three parts, the strophe, the antistrophe, and the epode. The priests going round the altar singing the praises of the gods, called the first entrance, when they turned to the left, the strophe; the second, turning to the right, they called antistrophe, or returning; and, lastly, standing before the altar, they sung the remainder, which they called the epode.

**ODOROUS**, or **ODORIFEROUS**, appellations given to whatever smells strongly, whether they be fetid or agreeable; but chiefly to things whose smell is brisk and agreeable.

**ODYSSEE**,

**ODYSSEE**, *οδυσσεΐα*, a celebrated epic poem of Homer, wherein are related the adventures of Ulysses, in his return from the siege of Troy. See the articles **EPIC** and **ILIAD**.

The moral of the *odyssey* is, that a person's absence from home, so that he cannot have an eye to his affairs, occasions great disorders; and, accordingly, the hero's absence is the principal and most essential action of the whole poem.

**OECONOMICS**, the art of managing the affairs of a family, or community; and hence the person who takes care of the revenues and other affairs of churches, monasteries, and the like, is termed *oconomus*.

**OECONOMY**, *οικονομία*, denotes, the prudent conduct, or discreet and frugal management, whether of a man's own estate, or that of another.

*Animal OECONOMY*, comprehends the various operations of nature, in the generation, nutrition, and preservation of animals.

**ŒCUMENICAL**, signifies the same with general, or universal; as *œcumenical council*, *bishop*, &c.

**OEDEMA**, or **PHLEGMATIC TUMOUR**, in medicine and surgery, a sort of tumour attended with paleness and cold, yielding little resistance, retaining the print of the finger when pressed with it, and accompanied with little or no pain. See the article **TUMOUR**.

**OENANTHE**, water-dropwort, in botany, a genus of plants, producing umbellated flowers, the universal corolla is difform and radiated; the proper flowers which form the disc are hermaphrodite, and composed of five inflexo-cordated petals; those of the rays are male, and have five large, unequal, bifid petals. The fruit is composed of two oval seeds, convex and striated on one side, and plane on the other.

A species of this genus, called hemlock dropwort, grows naturally by the sides of ditches and rivers in divers parts of England; it commonly grows four or five feet high, with strong jointed stalks, which being broken, emit a yellowish fetid juice; the leaves are somewhat like those of the common hemlock, but are of a lighter green.

This plant is one of the most poisonous we know of; the juice, which is at first like milk, turns afterwards to a saffron colour; if a person should swallow ever so little of this juice, it will so contract every part it touches, that there will immediately follow a terrible inflammation and gangrene; and what is worse, there has not hitherto been found any antidote against it; for which reason it ought to be very carefully avoided.

**OENELÆUM**, in pharmacy, a mixture of wine and oil, usually of thick black wine and oil of roses; said to be good for anointing wounds, to prevent an inflammation.

**OENOTHERA**, tree-primrose, in botany, a genus of plants, whose flower consists of four cordated plane petals, with eight subulated incurved filaments inserted in the tube of the calyx, and terminated with oblong incumbent antheræ. The fruit is a four-cornered, cylindraceous capsule, formed of four valves, and the same number of cells, containing a number of naked, angulated seeds.

This genus comprehends the *onagra* of Tournefort.

**OESOPHAGUS**, in anatomy, the gula, or gullet, is a membranaceous canal, reaching from the fauces to the stomach, and conveying into it the food taken in at the mouth. Its figure is somewhat like that of a funnel, and its upper part is called by anatomists the pharynx. Its situation is almost exactly behind the *aspera arteria*, and longitudinally with the vertebræ of the neck and back; but when it enters the cavity of the thorax, it turns a little to the right, on account of the aorta.

**OFFICE**, a particular charge or trust, or a dignity attended with a public function.

**OFFICE** also signifies a place or apartment appointed for officers to attend in, in order to discharge their respective duties and employments.

**OFFICE**, in architecture, denotes all the apartments appointed for the necessary occasions of a palace or great house; as kitchen, pantries, confectionaries, &c.

**OFFICE**, in the canon-law, is used for a benefice that has no jurisdiction annexed to it.

**OFFICER**, a person possessed of a post or office.

*Commission-OFFICERS*, are those appointed by the king's commission; such are all from the general to the cornet, inclusive, who are thus denominated in contradistinction to warrant officers, who are appointed by the colonel's or captain's warrant; as quarter-masters, sergeants, corporals, and even chaplains and surgeons.

*Field-OFFICERS* are such as command a whole regiment; as the colonel, lieutenant-colonel, and major.

*General-OFFICERS* are those whose command is not limited to a single company, troop, or regiment; but extends to a body of forces, composed of several regiments: such are the general, lieutenant-general, major-generals, and brigadiers.

*Staff-OFFICERS* are such as, in the king's presence, bear a white staff, or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: such are the lord-steward, lord-chamberlain, lord-treasurer, &c.

The white staff is taken for a commission, and at the king's death each of these officers breaks his staff over the hearse made for the king's body, and thus lays down his commission, and discharges all his inferior officers.

*Subaltern OFFICERS* are all who administer justice

office in the name of subjects; as those who act under the earl-marshal, admiral, &c. In the army, the subaltern officers are the lieutenants, cornets, ensigns, serjeants, and corporals.

**OFFICINAL**, in pharmacy, an appellation given to such medicines, whether simple or compound, as are required to be constantly kept in the apothecaries shops.

**OFFING**, or **OFFIN**, in the sea-language, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship: thus, if a ship from shore be seen sailing out to seaward, they say, she stands for the offing; and if a ship, having the shore near her, have another a good way without her, or towards the sea, they say, that ship is in the offing.

**OFF-SETS**, in gardening, are the young shoots that spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

**OFF-SETS**, in surveying, are perpendiculars let fall, and measuring from the stationary lines to the hedge, fence, or extremity of an enclosure.

**OGEE**, or **O. G.** in architecture, a moulding, consisting of two members, the one concave, and the other convex; or, of a round and a hollow, like an S. See the article **MOULDING** and **CYMATIUM**.

**OGIVE**, in architecture, an arch, or branch of a gothic vault; which, instead of being circular, passes diagonally from one angle to another, and forms a cross with the other arches.

**OIL**, *Oleum*, in natural history, an unctuous inflammable substance, drawn from several natural bodies, as animal and vegetable substances.

**OIL-MILL**, one that serves to bruise or break the nuts, olives, and other fruits and grains, whose juice is to be drawn by expression, to make oil.

**OIL-NUT**. See the article **RICINUS**.

**OIL-TREE**. See **RICINUS**.

**OINTMENT**, or **UNGUENT**, in pharmacy and surgery. See **UNGUENT**.

**OLDENLANDIA**, in botany, a genus of plants, whose flower consists of four oval patent petals, which are a little longer than the cup; it hath four stamina, topped with small antheræ. The fruit is a round capsule, with two cells, which are filled with many small seeds.

**OLEA**, the olive-tree, in botany. See the article **OLIVE**.

**OLEAGINOUS**, something that partakes of the nature of oil, or out of which oil may be expressed.

**OLEANDER**, *Nerium*, in botany. See **NERIUM**.

**OLEASTER**, *Elæagnus*, in botany. See the article **ELÆAGNUS**.

**OLECRANUM**, in anatomy, the posterior apophysis of the ulna, serving to form the eminence of the elbow.

**OLFACTORY NERVE**, the first pair of the head; so called from their being the immediate instruments of smelling.

**OLIBANUM**, frankincense, in pharmacy, a dry resinous substance, brought to us in detached pieces, or drops as it were, like those of mastic; but larger, and of a less pure and pellucid texture.

It is of a pale yellowish-white colour, but with some mixture of a brownish cast in it. It is moderately heavy; its smell is strong, but not disagreeable; and its taste bitter, acrid, and resinous.

The earliest accounts we have of any thing, tell us that frankincense was in use among the sacred rites and sacrifices; and it is used in many different parts of the world at this time, to the same purposes. As well, however, as the world has been at all times acquainted with the drug itself, we are not yet well acquainted with its history. The country which produces it is a much disputed point among authors: some affirm it was never found any where but in Arabia, and there only in that part called Sabæa, or, from this famous product, Arabia Thurifera: others are for bringing it from Ethiopia; and others from other places. If we are uncertain as to the place whence the olibanum is brought, we are much more as to the tree that produces it.

Olibanum is greatly commended by many against disorders of the head and breast, and against diarrhoeas and dysenteries, and profluvia of the menses, and fluor albus. Its dose is from ten grains to a drachm. It is esteemed by many a specific in pleurifies, especially when epidemic.

Externally it is used in fumigations for disorders of the head, and against catarrhs; and is an ingredient in some plasters. It is a noble balsam in consumptions, given in substance, or dissolved with the yolk of an egg, into the form of an emulsion. There is an oil made of it per deliquium, in the same manner as that of myrrh: this is done by putting the powder of it into the white of a boiled egg, in a cellar, till it runs into a liquor; this is esteemed a great cosmetic, and destroyer of pimples in the face. Dioscorides had his doubts about the internal use of olibanum in large doses; he talks of its bringing on madness, and even death; but none of the other Greek writers say any thing of its ill qualities, nor do we at present know any of them.

**OLIGARCHY**, a form of government, wherein the administration of affairs is lodged in the hands of a few persons.

**OLIVARIA CORPORA**, in anatomy, two eminences of the medulla oblongata; so called from their resembling an olive in shape.

**OLIVE-TREE**, *Olea*, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is cylindraceous and the length of the cup, and the limb is divided into four segments, which spread open; the stamina are two short subulated filaments, topped with erect antheræ. The fruit is

a smooth, oval, unilocular drupe, inclosing an oval-to-oblong wrinkled nut, with a kernel of the same shape.

There are several sorts of olive trees; the matured kind has a smooth ash-coloured bark and yellowish wood that has somewhat of a bitterish taste. The leaves are placed opposite, by pairs, and are oblong and narrow, almost like those of the willow, of a light green on their upper side, and hoary underneath. The flowers come out from the wings of the leaves in bunches, they are small and white, and are succeeded by the fruit, which ripens in autumn in the southern countries of Europe, where this plant is much cultivated. Olive trees will grow in almost any soil; in rich moist ground they grow larger than in poor land, but the fruit is of less esteem, because the oil made from it is not so good as that which is produced in a poorer soil. Chalky ground seems to suit them best, for the oil produced from trees growing on that kind of land is much finer, and will keep longer good, than any other. In this country, olive trees are kept more for curiosity than use; they are planted in pots or tubs, and preserved in green-houses in the winter. Olives are very oily and smooth, and therefore not good for the stomach, being apt to pall and relax it too much, as most things of the like properties generally do. This fruit is brought over to us pickled in salt and water, and the oil which is expressed from the fruit is also imported, and is of common use for fallads, &c. it is accounted heating, emollient, and vulnerary, and good against costiveness and the gripes.

*Wild-OLIVE*, *Eleagnus*, in botany. See the article *ELÆAGNUS*.

*OLIVE-COLOUR*, a yellow mingled with black. See *COLOUR*.

*OLYMPIAD*, *ολυμπιας*, in chronology, the space or period of four years, whereby the Greeks reckoned time; for the epocha or commencement of which, see the article *EPOCHA*.

*OLYMPIC GAMES*, were solemn games, famous among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated; and by some said to be first instituted by Jupiter, after his victory over the sons of Titan: others ascribe this institution to Hercules, not the son of Alcmena, but one of much greater antiquity; others to Pelops; and others, to Hercules the son of Alcmena. These games were so considerable, that the Greeks made them their epocha, distinguishing their years by the return of the olympics.

*OMBRE*, a celebrated game at cards, borrowed from the Spaniards, and played by two, three, or five persons, but generally by three.

*OMBRE DE SOLEIL*, shadow of the sun, in heraldry, is when the sun is borne in armory, so as that the eyes, nose, and mouth, which at other

times are represented, do not appear; and the colouring is thin, so that the field can appear through it.

*OMEN*, a certain accident and casual occurrence, that was thought to presage either good or evil.

*OMENTUM*, or *EPILOON*, the cawl, in anatomy, a membranaceous part, usually furnished with a large quantity of fat; being placed under the peritonæum, and immediately above the intestines.

It is called by some rete, and reticulum, from the number of holes appearing in it, when raised, and giving it the resemblance of a net.

As to its situation, it usually occupies only the upper part of the abdomen; though it is sometimes found extended to the lower part: its weight in a person not remarkably fat or lean, is about half a pound: its lower part is evidently loose and free; but in its upper part it is joined, anteriorly, to the bottom of the stomach, the duodenum, and the spleen; and posteriorly to the colon and pancreas.

It is composed of a very tender double membrane, forming a kind of pouch or cavity, called its bursa, and replete with fat, lodged in certain cellules, forming a kind of ducts, with certain areolæ, or membranaceous spaces between them.

Its arteries come from the cœliac, and are very numerous; its veins arise chiefly from the splenic branch of the vena portæ; and its nerves are from the intercostals and the par vagum. See the articles *ARTERY*, *VEIN*, &c.

It has a very remarkable aperture, by which it may be conveniently distended by inflation; and there are generally some small holes in it, though the large ones, from which it got the name rete, are adventitious.

The uses of the omentum are, 1. by its lubricity, to render the natural and necessary motions of the intestines easy: 2. to cherish and defend the intestines from cold: 3. to assist in the formation of the bile, the fatty part of which is wholly owing to the vessels of the omentum; every thing that returns from this part going to the liver: 4. to temperate the acrimony of the humours: and, probable, 5. to serve as all the other fat of the body, to give it nourishment, when it is incapable of being nourished any other way.

*OMPHALEA*, in botany, a genus of plants, producing male and female flowers; the male flower hath no corolla; the cup is cut into four segments, and contains an ovate receptacle, on the side of which are placed two or three antheræ: the female flower is like the male, excepting the generative parts; it hath a very short roundish germen, with a cylindric style, and a broad, obtuse, and almost trifid stigma: the fruit is ovate, fleshy, and trilocular, and the seeds are solitary and oblong.

*ONAGRA*, in botany, a name given by Tournefort

fort to the *oenothera* of Linnæus. See the article *OENOTHERA*.

*ONANIA*, or *ONANISM*, terms which some late empirics have framed, to denote the crime of self-pollution, mentioned in scripture to have been practised by Onan, and punished in him with death.

*ONDEE*, in heraldry, the same with wavy. See *WAVY*.

*ONEIROCRITICA*, *ονειροκριτική*, the art of interpreting dreams, or predicting future events from dreams.

*ONGLEE*, in heraldry, an appellation given to the talons or claws of beasts or birds, when borne of a different colour from that of the body of the animal.

*ONION*, *Cepa*, in botany, a genus of plants, having a bulbous root, consisting of various coats, the outermost of which are membranaceous, and the inner ones fleshy, with many fibres at the bottom; the leaves are long, fistular, round, and sharp at the points; the stalk is naked, upright, and rising to about four or five feet high; it is hollow, and swells out in the middle, on the top of which the flowers are collected in a spherical head; each flower consists of six oblong petals, with six subulated filaments, topped with oblong erect antheræ: the fruit is a broad, short, three-cornered capsule, having three cells and three valves, and contains a number of roundish angular seeds, of a black colour.

Onions are propagated by sowing their seeds in the spring, on good rich sandy ground; and when they are grown up about three inches high, they should be hoed out at about four or five inches asunder, leaving them singly; this is best done in dry weather, which should be repeated twice more, in order to keep the weeds from over-running them; in August the onions will be at their full growth, which is known by their blades falling to the ground, and shrivelling; but before they are quite withered, they should be drawn out, cropping off the extreme part of the blade and laying them on a dry spot, keeping them removed for a time till they are fit for housing, where they may be kept for winter use; reserving some of the firmest, largest, and best shaped, in the spring, to plant for seed, which, when run up, should be staked, to prevent the winds from blowing them down.

Onion-seed also may be sown in beds in the month of August, for a supply in the spring; and likewise they may be sown in the spring, in beds, to draw up for young sallads, after the Michaelmas onions are grown too large for that purpose.

There are several sorts of onions, as the *Strafburgh onion*, *Spanish onion*, *Portugal onion*, &c.

Onions are chiefly used for culinary purposes, and are eaten raw by some, and roasted by others, but are more commonly boiled: they are windy, heating, and cause thirst, and therefore are bad for hot constitutions; however, when boiled and mix-

ed with honey, they are good in disorders of the lungs, arising from a thick clammy phlegm: they are also in great esteem to draw and suppurate all kinds of tumours; roasted, and applied to the ear, they help to ripen, break, and cleanse away, imposthumations in the head, which sometimes cannot be influenced by any other means: a cataplasm of roasted onions and fresh-butter, is an excellent external application for the piles.

This genus is included by Linnæus among the alliums, or garlic. See *ALLIUM*.

*ONOCLEA*, in botany, a genus of plants of the fern kind, the fructifications of which grow in a clustered spike; it hath a globose unilocular capsule, opening with five valves, which are lanceolated and acute: the seeds are numerous, small, dusty, and hairy.

*ONOMATOPOEIA*, in grammar and rhetoric, a figure where words are formed to resemble the sound made by the things signified; as the buzz of bees, the cackling of hens, &c.

*ONONIS*, rest-harrow, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is cordated, striated, and depressed on the sides; the alæ are ovate, and shorter than the vexillum; and the carina is acuminate, and longer than the alæ: the fruit is a turgid, rhomboidal, unilocular pod, containing a few reniform seeds.

There are several species belonging to this genus, but the common sort (known by the name of the prickly rest-harrow) which grows naturally in many parts of England, with purple flowers, has a strong creeping root, which spreads far in the ground; the stalks are slender, rough, reddish, hairy, and full of prickles; they are beset with leaves of a roundish form, slightly crenated, hairy, of a dark green colour, and glutinous to the touch.

The root and leaves of this plant are accounted attenuant and discutient, being chiefly prescribed in the piles, jaundice, and obstructions of the viscera.

*ONOPORDUM*, woolly-thistle, in botany, a genus of plants, producing compound tubulose flowers; the proper ones are monopetalous and funnel-shaped: the seeds are single, crowned with a hairy down, and placed in the cup.

The common *onopordum*, which grows naturally in many parts of England, is a biennial plant, with many large downy leaves, which are sinuated at their edges, and are prickly; the stalks are four or five feet high, dividing upwards into many branches, and are terminated by scaly heads of purple flowers, which come out in June.

This species is said to be good against cancers, &c.

*ONOSMA*, in botany, a genus of plants, whose flower is monopetalous and campanulated, with a very short tube; the stamina are five short subulated filaments, topped with erect arrow-shaped antheræ: there is no pericarpium; but the cup, which is immutable, contains four ovate seeds.

**ONTOLOGY**, or **ONTOSOPHY**, the science or doctrine of being, in the general or abstract; coinciding with what is otherwise called metaphysics.

**ONYX**, in natural history, one of the semi-pellucid gems, with variously coloured zones, but none red; being composed of crystal, debased by a small admixture of earth; and made up either of a number of flat plates, or of a series of coats surrounding a central nucleus, and separated from each other by veins of a different colour, resembling zones or belts.

**OOST**, a kiln for drying hops after they are picked from the stalks.

**OPACITY**, in philosophy, a quality of bodies which renders them impervious to the rays of light. See **LIGHT**.

**OPAL**, in natural history, a gem of a very peculiar kind, and has been esteemed by many, in all ages, of very great value; though at present it is of less value, in proportion to its size, than any of the finer gems.

It is softer than any other of the fine gems, and is difficult to polish to any degree of nicety: it is found of various shapes and sizes; its most frequent bigness is between that of a pea and a horse-bean; but it is found as small as the head of a large pin, and has been seen of the size of a large walnut. Its figure is very various and uncertain, but it is never found in a chryselliform or columnar state; its most usual shape is an irregularly oblong one, convex above, flattened at bottom, and dented with various sinuosities at its sides.

It is often found among the loose earth of mountains, sometimes on the shores of rivers, and not unfrequently bedded in the coarser kinds of jasper. It is found in Egypt, Arabia, some parts of the East-Indies, and in many parts of Europe; those of Europe are principally from Bohemia, and are of a greenish or greyish colour; the colour of other opals much resemble the finest mother of pearl, its basis seeming a bluish or greyish white, but with a property of reflecting all the colours of the rainbow, as turned differently to the light.

**OPALIA**, in antiquity, feasts celebrated at Rome in honour of the goddess Ops.

**OPEN FLANK**, in fortification, that part of the flank which is covered by the orillon. See the article **FLANK**.

**OPENING of Trenches**, is the first breaking of ground by the besiegers, in order to carry on their approaches towards a place. See **TRENCH**.

**OPERA**, a dramatic composition set to music, and sung on the stage, accompanied with musical instruments, and enriched with magnificent dresses, machines, and other decorations.

**OPERATION**, in general, the act of exerting or exercising some power or faculty, upon which an effect follows.

**OPERATION**, in surgery and medicine, denotes a methodical action of the hand on the human body, in order to re-establish health.

**OPERATIONS**, in chemistry, denote the processes or experiments whereby bodies are changed agreeably to the rules of the art, and to the end proposed therein.

**OPHIOGLOSSUM**, adder's-tongue, in botany, a genus of cryptogamous plants of the fern kind; the root hath many fibres gathered together, from which arise, on a pedicle, a single leaf, which is fleshy, smooth, upright, and without nerves; from that part of the leaf that joins to the pedicle, there proceeds a spike which resembles a serpent's tongue, that terminates in a point, and is denated on each side like a file; it is divided into several small cells, which contain a great number of very small oval seeds, like meal or dust, which are thrown out when ripe.

Adder's-tongue grows wild, in moist meadows, in several parts of England; it is accounted a vulnerary, and is used both externally and internally, and is thought to be good for ulcers when bruised and applied as a cataplasm.

**OPHIORHIZA**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped, and the limb cut into five obtuse patent segments; it hath five slender filaments, topped with oblong antheræ. The fruit is a broad bilobate capsule, containing many angulated seeds.

**OPHIOXYLON**, in botany, a genus of the polygamia-monoecia class of plants, the hermaphrodite flowers are monopetalous and infundibuliform, with five very short filaments topped with pointed antheræ; the male flower hath a cylindric nectarium in the mouth of the corolla, with two very short stamina. The fruit is a double berry, having two cells, and the seeds are solitary and roundish.

**OPHITES**, in natural history, a sort of variegated marble, of a dusky-green ground, sprinkled with spots of a lighter green, otherwise called serpentine.

**OPHITES**, in church history, Christian heretics, so called from the veneration they had for the serpent that tempted Eve, and the worship they paid to a real serpent: they pretended that the serpent was Jesus Christ, and that he taught men the knowledge of good and evil: they distinguished between Jesus and Christ; Jesus, they said, was born of the Virgin, but Christ came down from heaven to be united with him: Jesus was crucified, but Christ had left him, to return to heaven. They distinguished the God of the Jews, whom they termed Jaldabaoth, from the supreme God; to the former they ascribed the body, to the latter the soul of men. They had a live serpent, which they kept in a kind of cage; at certain times they opened the cage door and called the serpent; the animal came out, and mounting

mounting upon the table, twined itself about some loaves of bread; this bread they broke, and distributed it to the company, who all kissed the serpent: this they called their eucharist.

**OPHRYS**, *twyblade*, in botany, a genus of plants, whose flower consists of five oblong petals, four of which are ascendend, and join, and the lower one is bifid; it hath a dependent nectarium, which is carinated; behind the stamina are two very short filaments, topped with erect antheræ. The fruit is an oval, three-cornered, obtuse capsule, with one cell, opening with three valves, containing a great number of small seeds like dust.

**OPHTHALMIA**, *οφθαλμία*, in medicine, an inflammation of the membranes which invest the eye; especially of the adnata, or albugineous coat. See the article **EYE**.

**OPHTHALMICS**, medicines good in disorders of the eyes. See **EYE**.

**OPHTHALMIC NERVES**, the fifth pair of the head. See the article **NERVE**.

**OPIATES**, medicines of a thicker consistence than a syrup, prepared with opium scarcely fluid. They consist of various ingredients, made up with honey or syrup; and are to be used for a long time either for purgative, alterative, or corroborative intentions. Hence there are opiates of three kinds; that is, of a purgative, an alterative, and of a corroborating quality.

**OPINION**, is defined to be an assent of the mind to propositions not evidently true at first sight.

**OPIUM**, in the materia medica, is an inspissated juice, partly of the resinous, and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry; but in general, easily receives an impression from the finger: its colour is a brownish yellow, so very dark and dusky that at first sight it appears black: it has a dead and faint smell, and its taste is very bitter and acrid. It is to be chosen moderately firm, and not too soft; its smell and taste should be very strong, and care is to be taken that there is no dirty or stony matter in it.

Opium is the juice of the papaver album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which on being stuck into the head makes at once five long cuts in it; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and put up in a vessel which he carries fastened to his girdle: at the same time that this opium is collected, the opposite side of the poppy head is wounded, and the opium collected from it the next day. They distinguish however the produce of the first wounds from that of the succeeding

ones, for the first juice afforded by the plant is greatly superior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it a long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the consistence of pitch; and then work it up with their hands, and form it into cakes or rolls for sale.

Opium at present is in great esteem, and is one of the most valuable of all the simple medicines: applied externally it is emollient, relaxing and discutient, and greatly promotes suppuration; if long kept upon the skin it takes off the air, and always occasions an itching in it; sometimes it exulcerates it, and raises little blisters if applied to a tender part. Laid on the perinæum it promotes venereal inclinations; and sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the sutures of the skull, for it has been known to have the most terrible effects in this application, and even to bring on death itself.

Opium, taken internally, removes melancholy, eases pain and disposes to sleep; in many cases removes hæmorrhages, provokes sweating, and is a provocation to venery; and in general has a greater effect on women and children than on men. A moderate dose is commonly under a grain, though according to the circumstances two grains, or even three may be within the limits of this denomination; but custom will make people bear a dram or more, tho' in this case nature is vitiated, and nothing is to be hence judged in regard to others. If given dissolved, it operates in half an hour; if in a solid form, as in pills, or the like, it is sometimes an hour and a half. Its first effect, in this case, is the making the patient cheerful, as if he had drank moderately of wine, and at the same time bold and above the fear of danger; for which reason the Turks always take it, when they are going to battle. A very immoderate dose brings on a sort of drunkenness, much like that occasioned by an immoderate quantity of strong liquors; cheerfulness and loud laughter at first, then a relaxation of the limbs, a loss of memory, and lightheadedness; then vertigoes, dimness of the eyes, with a laxity of the cornea and a dilatation of the pupils, a slowness of the pulse, redness of the face, relaxation of the under jaws, swelling of the lips, difficulty of breathing, painful erection of the penis, convulsions, cold sweats, and finally death. Those who escape are usually relieved by a great number of stools, or profuse sweats. People who have gradually accustomed themselves to an immoderate use of opium, are subject to relaxations and weaknesses of all the parts of the body: they are apt to be faint, idle and thoughtless; and are generally in a stupid and uncomfortable state, except just

after they have taken a fresh dose, in short, they lose their appetite, and grow old before their time.

Prepared opium, commonly called extract of opium, is made by dissolving opium in a sufficient quantity of water with a gentle heat; then straining the solution from the fæces, and evaporating it to the consistence of honey. Tincture of opium, or liquid laudanum, otherwise called the thebaic tincture, is made as follows: take of prepared opium two ounces; of cinnamon and cloves, each one drachm; of white-wine, one pint: infuse them a week without heat, and then filtre it through paper. Quincy observes of this preparation, that the addition of the spices are of no use.

OPOBALSAMUM, in the materia medica, the same with the true balsam. See the article BALSAM.

OPOPANAX, in the materia medica, is a gum-resin of a tolerably firm texture, usually brought to us in loose granules or drops, and sometimes in large masses, formed of a number of these, connected by a quantity of matter of the same kind; but these are usually loaded with extraneous matter, and are greatly inferior to the pure loose kind. The drops or granules of the fine opopanax, are on the outside of a brownish red-colour, and of a dusky-yellowish or whitish colour within: they are of a somewhat unctuous appearance, smooth on the surface, and are to be chosen in clear pieces, of a strong smell, and acrid taste.

Opopanax is attenuating and discutient, and is gently purgative; it dispels flatulencies, and is good in asthma, in inveterate coughs, and in disorders of the head and nerves. It also promotes the menses, and is good against all obstructions of the viscera.

OPOSSUM, in zoology, a species of didelphis, with the paps within the abdomen. See DIDELPHIS.

The opossum is a very singular animal, about fifteen inches long from the extremity of the nose to the rump; and its tail is equal in length to the whole body: the legs are robust, and the feet armed with sharp, long and crooked claws. But what is most singular in this animal, is that the skin of the belly of the female is loose, forming a kind of pouch or bag, with an aperture in it, at which, in time of danger, it takes in its young.

OPPONENT, a person who withstands or opposes another.

This term is chiefly used in scholastic or academic disputes or exercises, where a person who opposes a thesis, or impugns it by his objections, is called opponent.

OPPOSITES, *Opposita*, among logicians, simply taken, are such things as differ among themselves, but so as not to differ in like manner from some third.

OPPOSITION, in logic, the disagreement be-

tween propositions, which have the same subject and the same predicate.

OPPOSITION, in astronomy, is that aspect or situation of two stars or planets, wherein they are diametrically opposite to each other, or  $180^{\circ}$  asunder.

OPPOSITION, in geometry, the relation of two things, between which a line may be drawn perpendicular to both.

OPPOSITION, in rhetoric, a figure whereby two things are joined, which seem incompatible; as *a wise folly*.

OPTATIVE MOOD, in grammar, that which serves to express an ardent desire or wish for something. See the article MOOD.

OPTICS, *Optica*, taken properly and simply, is that science which teaches the properties of direct vision; but in a larger sense, it may comprehend the whole doctrine of light and colours, and all the phenomena of visible objects. In this large sense, the incomparable Sir Isaac Newton calls his book of light and colours, optics; or it is a mathematical science that treats of light in general, and of every thing that is seen with direct rays; and explains the several properties and effects of vision in general, and properly of that which is direct and ordinary. For when the rays of light are considered as reflected, the science which teaches their laws and properties, is called catoptrics; and when the refraction of rays is considered, and the laws and nature of it explained and demonstrated, the science is called dioptrics. So that optics comprehends the whole, of which catoptrics and dioptrics are the two parts.

OPULUS, marsh elder, in botany, an umbelliferous plant, growing naturally in marshy lands in several parts of England; it rises to the height of sixteen or eighteen feet, and is divided into several branches which come out opposite, and are apt to grow irregular; they are covered with a smooth ash coloured bark, are very tender and brittle, and full of a white spongy pith: the leaves are placed opposite, and are large and angular, jagged on their edges, and of a light green. The flowers are monopetalous and campanulated, quinquefid at the limb, and reflexed; they come out at the ends of the branches in June, and grow in large umbels; they are of a white colour, and are succeeded by oval berries, which when ripe are of a scarlet colour.

OPUNTIA, the Indian fig, in botany, a genus of plants, whose flower is composed of several obtuse, concave petals, placed in a circular order; the filaments are numerous, subulated, inserted in the cup, and terminated by oblong erect antheræ; the fruit is a fleshy umbilicated berry, with one cell containing a number of small roundish seeds. There are several kinds of opuntia, which are all natives of America; they are armed with spines, which come

come out in clusters on the sides of the leaves, or rather branches, as they have no proper leaves; they grow either in a ramose form in some species, or dichotomous in others, and are kept in our green-houses among other succulent plants, for the singularity of their appearance. These plants are easily propagated by cutting off their branches, at the joints, in the summer months, which should be laid in a warm dry place for sometime to heal the wounded part; after which they may be planted in a dry rubbishy soil, giving them but little water, as they are very succulent, which would otherwise rot them; and to have them in perfection, they should not be exposed to the open air at any time, for they thrive much better when kept under glasses. It is on a species of opuntia that the cochineal animal feeds. See cochineal. This genus is included by Linnæus, among the cactus, which see.

OR, in heraldry, denotes yellow or gold-colour. See COLOUR and METAL.

ORACLE, among the heathens, was the answer which the gods were supposed to give to those who consulted them upon any affair of importance; it is also used for the god who it was thought gave the answer, and the place where it was given.

ORACH, *Atriplex*, in botany. See the article ATRIPLEX.

ORAL, something delivered by word of mouth, without being committed to writing; in which sense we say, oral law, oral tradition, &c.

ORANGE, *Aurantium*, in botany, an ever-green-tree; it hath a thick, woody, branched root, which spreads very much, and is of a yellow colour within; the trunk is hard, whitish within, has an agreeable smell, and is covered with a brownish smooth bark; the branches are numerous, flexible, of a beautiful green, and armed with a few thorns; the leaves are thick, smooth, broad, of an oval-lanceolated form, ending in a point with a foliated pedicle, in the shape of a heart (by which it is distinguished from the lemon and citron trees) and when held up to the light there appears a sort of small holes in them: the flowers grow in bunches, and are rosaceous, each consisting of a monophyllous cup, indented in five parts: the corolla is composed of five white, oblong, patent petals, with many filaments, topped with yellow oblong antheræ; in the center is placed an orbicular germen, which sustains a cylindrical style, crowned with a globose stigma, becoming afterwards a well-known globular fleshy fruit, divided into nine cells, each containing two oval callous seeds.

There are several kinds of orange-trees, as the Seville orange, the China orange, the willow-leaved orange, the shaddock orange, the dwarf or nutmeg orange, the curled-leaved orange, the striped curled-leaved orange, the double-flowering orange, the horned orange, the large-warted orange, with

other varieties, which are cultivated in England more for curiosity than use.

Orange-trees are propagated by inoculation, on stocks raised from the kernels, which should be sown on a moderate hot-bed, in the spring; and when the plants are up three or four inches, they should be planted singly in small pots in good rich earth, and plunged into a fresh bed, observing to keep them shaded till they are properly rooted, and also to keep them well watered in hot-weather; in autumn they should be put in the green-house, where they may remain till the spring, when it would not be amiss to plunge them again in a moderate hot-bed which will greatly facilitate their growth; and by hardening them by degrees as the summer advances, they will be fit for inoculation in August, which is the proper season for that operation on this plant; at which time, choice should be made of cuttings from healthy and fruitful trees, observing that the shoots are round and the buds not ridged, such seldom succeeding. When the stocks are inoculated, they should be plunged in a moderate warmth, whether tan or dung (tan is best) and covered with glasses, giving proper air at times: in about a month it will be discoverable what buds have taken (at which time the bandage should be loosened); after which, they should be sheltered in the green-house, and in the spring, headed down within two or three inches of the bud, which will soon put forth its shoot, which shoot should be trained, by degrees, as it advances, in order to form a handsome tree; as they increase in size, they should occasionally be shifted into larger pots; once in two years will be sufficient.

If old orange-trees have been mismanaged, so as their tops are become unsightly or partly decayed, the best method to restore them, is to take them out of the tubs or pots in the spring, pruning their roots and heads, plant them into fresh earth, and plunge them into a tan-bed in a hot-house, where they may continue the succeeding summer and winter, by which time they will have renewed their heads; when they may be placed among the others which are in good order.

Orange-trees may also be trained against a wall, in the manner peaches are, and frames of glass placed slopewise over them in winter, which may be so contrived as to be removed quite away in summer; by this method the fruit will be very large, and more numerous than those kept in the common way; also the fruit will ripen well, and be fit for use; but it will be proper to have a flue in the front in winter (an iron or tin one is best, as it can easily be moved away in summer) by which means there will be no hazard of losing the trees in severe winters.

The flowers of orange-trees are justly esteemed one of the finest perfumes, and though little used in medicine,

medicine, yet the water distilled from them is accounted stomachic, cordial, and carminative. The peel of oranges is an excellent bitter, it strengthens the stomach, helps digestion, attenuates gross humours, dissolves wind, and eases the cholic; it is an ingredient in tinctures, which, mixed with wine and drank before dinner, creates an appetite: the essential oil distilled from the rind, is also proper for the same uses when two or three drops are taken upon sugar, as well as the peel when it is candied. The pulp of sweet oranges is cooling, quenches thirst, and excites the appetite; but the juice of sour oranges, not only serves to make a cooling drink in hot weather, but is of late found to be excellent against the scurvy.

*Mock-ORANGE*, *Philadelphus*, in botany. See *PHILADELPHUS*.

*ORANGE-COLOUR*, among dyers, one that partakes equally of red and yellow. See the articles *COLOUR* and *DYEING*.

*ORANGERY*, in gardening, a green-house, purposely adapted for the preservation of orangtre es in winter: it also denotes a well sheltered place, where orange trees are placed without doors in the summer season.

*ORATION*, in rhetoric, a speech or harangue, composed according to the rules of oratory, and spoke in public.

*ORATORY*, *Oratoria*, the art of speaking well, otherwise called rhetoric. See the article *RHETORIC*.

*ORB*, *Orbis*, in astronomy, &c. denotes an hollow globe or sphere. See the articles *GLOBE* and *SPHERE*.

*ORBICULARE Os*, in anatomy, a little bone of the ear, so called from its figure. See the article *EAR*.

*ORBICULARIS*, in anatomy, an appellation given to the constrictor-muscle of the lips; as also to the constrictor of the upper eye-lid, which is single, and rises from the upper apophysis of the maxillary bone, near the larger canthus of the eye, and surrounds the eye-lid with a series of orbicular fibres, serving to shut it; and, in this action, it also depresses and draws forward the eye-brow, and elevates the lower eye-lid.

Some also give the name of orbicularis intestini, to the sphincter of the anus.

*ORBIS MAGNUS*, in astronomy, denotes the earth's orbit, in its annual revolution round the sun.

*ORBIT*, *Orbita*, in astronomy, the path of a planet or comet, or the curve that it describes in its revolution round its central body: thus the earth's orbit is the curve which it describes in its annual course, and usually called the ecliptic. See the article *ECLIPTIC*.

*ORCHARD*, a plantation of fruit-trees. In planting an orchard, great care should be taken that

the soil is suitable to the trees planted in it; and that they are procured from a soil nearly of the same kind, or rather poorer than that laid out for an orchard. As to the situation, an easy rising ground, open to the south-east, is to be preferred. Mr. Miller recommends planting the trees fourscore feet asunder, but not in regular rows; and would have the ground between the trees plowed, and sown with wheat and other crops, in the same manner as if it was clear from trees, by which means the trees will be more vigorous and healthy, will abide much longer, and produce better fruit. If the ground has been pasture, the green-sward should be plowed in the spring before the trees are planted; and if it be suffered to lie a summer fallow, it will greatly mend it, provided it be stirred two or three times to rot the grass and prevent the growing of weeds. At Michaelmas it should be plowed pretty deep, in order to make it loose for the roots of the trees, which if the soil be dry, should be planted in October; but if it be moist, the beginning of March will be a better season. If several sorts of fruit trees are to be planted on the same spot, you should observe to plant the largest growing trees backwards, and so proceed to those of less growth, continuing the same method quite through the whole plantation; by which means the sun and air will more easily pass through the whole orchard. When you have planted the trees, you should support them with stakes, to prevent their being blown out of the ground by the wind; and the following spring, if the season should prove dry, cut a quantity of green turf, and lay it about the roots, with the grass downwards; by which means a great expence of watering will be saved; and after the first year they will be out of danger. Whenever you plow the ground betwixt these trees, you must be careful not to go too deep amongst their roots, which would greatly damage the trees; but if you do it cautiously, your stirring the face of the ground will be of great service to them: though you should observe, never to sow too near the tree, nor to suffer any great rooting weeds to grow about them; because this would starve them, by exhausting the goodness of the soil, which every two or three years should be mended with dung or other manure, that will be absolutely necessary for the crops sown between. These trees, after they are planted out, will require no other pruning besides cutting off their bad branches, or such as cross each other.

*ORCHESTRA*, in the antient theatres, a place in the form of a semi-circle, where the dancing was performed.

*ORCHIS*, in botany, a genus of plants, whose flower hath five petals with a nectarium of a corniculated form, with two very short slender filaments joining to the pointal, with oval erect antheræ. The fruit is an oblong unilocular capsule, with three carinated valves opening on the sides, but cohering

bering at the top and bottom, the seeds are numerous and very small like dust. There are several species of orchis which grow wild in divers parts of England; the odd appearance and beauty of their flowers makes them well deserving of a place in gardens; they are propagated by their roots, which are composed of two tubercles almost round, fleshy, and of the size of nutmegs; the leaves are in most sorts oblong, some of which are spotted; the stalks rise to the height of a foot, and are round, streaked, and encompassed with one or two leaves; and on the top is placed a spike of flowers in May or June. Orchis is accounted a restorative and strengthener in weak decaying constitutions.

**ORDEAL**, a form of trial, or of discovering innocence or guilt, formerly practised over almost all Europe, and which prevailed in England from the time of Edward the confessor, till it was abolished by a declaration of Henry III. It was called purgatio vulgaris, or judicium, in opposition to bellum or combat, the other form of purgation; and was of various kinds, as that of fire, that of red hot iron, that of water, that of judicial pottage, that of hallowed cheese, that of the green cross, and that of dice laid on relics covered with a woollen cloth. To each of which kinds particular masses were appointed.

In England, an offender, on being arraigned and pleading not guilty, had it in his choice to put himself upon God and his country; that is upon the verdict of a jury; or upon God alone, on which account it was called the judgment of God, it being presumed that God would deliver the innocent. The more popular kinds of ordeal were those of red-hot iron and water; the first for free-men and people of fashion, and the last for peasants. That by fire as practised here, was the person's walking bare-footed and blindfold over nine red-hot plough shares; and if he escaped unhurt, he was acquitted, otherwise condemned. That of water was of two kinds, viz. either with hot water or cold; the former was where the person suspected put his arm or leg into scalding water, and brought it out unhurt; and the latter was when his body was not, contrary to the course of nature, borne up by the water.

**ORDER**, in architecture, is a system of the several members, ornaments and proportions of columns and pilasters; or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole.

M. Le Clerc defines an order to be a column charged with an intabature, and supported on a pedestal.

**ORDER** is also used for a division or class of any thing: thus the tribe of animals called birds, is subdivided into six orders. See the article **ORNITHOLOGY**.

*Holy ORDERS*, a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See **ORDINATION**.

*Military ORDERS*, are companies of knights, instituted by kings and princes; either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

*Religious ORDERS*, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.

**ORDERS of curves**, in geometry. See the article **CURVE**.

**ORDINANCE**, or **ORDONNANCE**, a law statute, or command of a sovereign, or superior; thus the acts of parliament are sometimes termed ordinances of parliament.

**ORDINARY**, or *honourable ORDINARY*, in heraldry, a denomination given to certain charges properly belonging to that art. The honourable ordinaries are ten in number; viz. the chief, pale, bend, fesse, bar, cross, saltier, chevron, bordure, and orle. For which see **CHIEF**, **PALE**, &c.

**ORDINATES**, or **ORDINATE APPLICATES**, in geometry, are parallel lines, terminating in a curve, and bisected by a diameter. The half of these, is properly the semi-ordinate, though commonly called ordinate. See **CURVE**, **PARABOLA**, **HYPERBOLA**, &c.

**ORDINATION**, the act of conferring holy orders, or of initiating a person into the priesthood by prayer, and the laying on of hands. Ordination has always been esteemed the principal prerogative of bishops, and they still retain the function as a mark of spiritual sovereignty in their diocese. Without ordination, no person can receive any benefice, parsonage vicarage, &c. A clerk must be twenty three years of age before he can have any share in the ministry; and twenty four, before he can be ordained, and by that means be permitted to administer the sacraments. A bishop on the ordination of clergymen, is to examine them in the presence of the ministers who assist him at the imposition of hands; and in case any crime, as drunkenness, perjury, forgery, &c. be alledged against any one that is to be ordained, either priest or deacon, the bishop ought to desist from ordaining him. The person to be ordained is to bring a testimonial of his life and doctrine to the bishop, and give an account of his faith in Latin, and both priests and deacons are obliged to subscribe the thirty-nine articles.

**ORDNANCE**, a general name for all sorts of great guns, used in war. See the articles **CANNON** and **GUN**.

**ORDONNANCE**, in painting, is used for the disposition of the parts of a picture, either with regard to the whole piece, or to the several parts; as the groups, masses, contrasts, &c.

**ORDONNANCE**, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole, and to one another; or, as Mr. Evelyn expresses it, determining the measure of what is assigned to the several apartments.

**ORE**, in natural history, the compound mineral glebe, earth, stone, or other substance; which is rich enough in metallic particles, to be worth the while of being purified; and by this means to separate the metal from it, whether gold, silver, copper, iron, tin, &c. See **METAL**, **Gold**, &c.

**ORGAL**, among dyers, denotes the lees of wine dried. See **DYEING**.

**ORGAN**, *органъ*, in general, is an instrument, or machine, designed for the production of some certain action or operation; in which sense, the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called organs. See the articles **POWER**, **MACHINE**, **VEIN**, **ARTERY**, &c.

**ORGAN**, in music, the largest and most harmonious wind-instrument.

The invention of the organ is very antient, tho' it is agreed that it was very little used till the eighth century. It seems to have been borrowed from the Greeks. Vitruvius describes an hydraulic one in his tenth book of architecture.

**Hydraulic ORGAN**, denotes a musical machine that plays by means of water instead of wind.

Of these there are several in Italy, in the grottoes of vineyards.

**ORGASM**, *Orgasmus*, an extacy, or impetuous desire of coition, occasioned by a turgescency of the feminal vessels.

Certain female animals have an orgasm at particular seasons of the year.

**ORGUES**, in the military art, are thick, long, pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope, or cord, over the gate-way of a strong place, perpendicularly, to be let fall in case of an enemy.

Their disposition is such, that they stop the passage of the gate, and are preferable to hersees and portcullises; because they may be either broke by a petard, or they may be stopped in their falling down; but a petard is useless against an orgue, for if it break one or two of the pieces, they immediately fall down again; and fill up the vacancy; or if they stop one or two of the pieces from falling, it is no hindrance to the rest.

**ORGUES**, is also used for a machine, composed of several harquebuss or musquet-barrels, bound together, by means whereof several explosions are made at the same time, used to defend breaches and other places attacked.

**ORICHALCUM**, or **AURICHALCUM**, brass. See **BRASS**.

**ORIENT**, *Oriens*, in geography and astronomy, the east, or east point of the horizon; thus called, because it is the place where the sun rises.

Hence, the equinoxial orient is used for that point of the horizon wherein the sun rises, when he is in the equator, or when he enters the signs of Aries and Libra; æstival orient, is the point wherein the sun rises in the middle of summer, when the days are longest; and the hybernal orient, the point where the sun rises in the middle of winter, when the days are shortest.

**ORIENTAL**, something situated towards the east with regard to us, in opposition to occidental. See **OCCIDENTAL**.

**ORIFICE**, the mouth, or aperture of a tube, pipe, or other cavity.

It is also used for the aperture of a wound, or ulcer. See **WOUND** and **ULCER**.

**ORIGINISTS**, in church history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen.

The Origenists maintained, that the souls of men had a pre-existent state, that they were holy intelligences, and had sinned in heaven before the body was created; that Christ is only the son of God by adoption, that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues, one after another; that in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men, and that their punishment, and that of the damned, will continue only for a certain limited time.

**ORIGINAL**, a first draught or design of any thing, which serves as a model to be imitated or copied.

**ORIGINAL SIN**, the crime of eating the forbidden fruit, of which it is said, all mankind are guilty at their conception by the imputation of Adam's transgression; which is accounted for by supposing that Adam, as he was to be the father, was also the federal head, and representative of the whole human race; and that on his sinning, all that were to spring from him partook of his crime.

**ORILLON**, in fortification, is a small rounding of earth faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy.

**ORION**, in astronomy, one of the constellations of the southern hemisphere.

The word is formed from the Greek *ορειν*, to make water; the antients supposing that it raised tempests at its rising and setting.

The stars in the constellation Orion, in Ptolemy's catalogue are 37, in Tycho's 62, in the Britannic catalogue 80. The names, situations, magnitudes, longitudes, and latitudes of which are as follow:

# ORI

## Names and situations of the stars.

ORION'S RING, in astronomy, a constellation more usually called eridanus. See the article ERIDANUS.

ORIGANUM, *Origany*, or wild marjorum, in botany, a genus of plants, whose flowers are ringent, and collected in an imbricated spike; the tube of the corolla is cylindric and compressed; the upper lip is plane, obtuse, erect, and emarginated; and the lower one is trifid: it hath four stamina, two of which are longer than the others: there is no pericarpium, but the cup, which is connivent, contains four ovate seeds.

The common origany, which grows wild in many parts of England, is diaphoretic and diuretic, and may be used in the manner of tea in the asthma and a violent cough; the powder of the leaves and

flowers, dried in the shade, is cephalic, and is a principal ingredient in the herb-snuff: it helps digestion, dissolves wind, and is used externally in baths for the feet.

ORLE, ORLET, or ORLO, in architecture, a fillet under the ovolo or quarter-round of a capital. When it is at the top or bottom of the shaft, it is called cincture. See the article CINCTURE.

ORLE, in heraldry, an ordinary in form of a fillet draw round the shield, near the edge or extremity thereof, leaving the field vacant in the middle. Its breadth is but half that of the tressure or bordure, which contains a sixth part of the shield; and the orle, only a twelfth: besides that the orle is its own breadth distant from the edge of the shield, whereas the bordure comes to the edge itself. The form

form of the orle is the same with that of the shield, whence it resembles an escutcheon.

ORNAMENTS, in architecture, are used to signify all the sculpture or carved-work, wherewith a piece of architecture is enriched.

ORNITHOGALUM, star of Bethlehem, in botany, a genus of plants, whose flower consists of six petals of a lanceolated figure, from the base to the middle, erect, but spreading upwards, and persistent; it hath six stamina, which are shorter than the corolla: the fruit is a roundish, angulated, trilocular capsule, formed of three valves, and contains a number of roundish seeds.

The roots of ornithogalum are of the bulbous kind, and are easily propagated by off-sets, in July or August. This genus includes the stellaris of Dillenius.

ORNITHOLOGY, that branch of zoology which treats of birds. See BIRD.

Linnaeus, whose ornithology we have chiefly followed, arranges the whole class of birds under six orders, according to the different figures of their beaks, viz.

1. The accipitres, or birds with uncinated or hooked beaks.

2. The picæ, or birds that have convex and compressed beaks.

3. The anseres, comprehending such birds as have depressed, and dentated, or serrated beaks.

4. The scolopaces, or those furnished with subcylindric and obtuse beaks.

5. The gallinæ, or birds which have the beak of a conic form, but crooked, and the upper chap imbricated.

6. The passeres, or birds with conic and sharp-pointed beaks.

In the description of birds, the feet, wings, and tail, are chiefly attended to.

In most birds the toes are four in number, three standing forwards, and one backwards: in some, two toes stand forwards, and two backwards: some feet, again, are palmated, or have the toes connected together by a membrane; and others, semi-palmated.

With regard to the wings, the long quill-feathers, are called by authors remiges, as serving to fly with; and the other feathers, placed over the rest of the body, rectrices. The long feathers of the tail are called rectrices, as serving to steer the bird's course through the air.

As to the other terms made use of in the description of birds, they are these: cera expresses the membrane or naked tunic, which surrounds and extends itself over more or less of the base of the beak; urrhogium is the rump; and as to other terms, they will be found explained under their several heads.

ORNITHOPODIUM, or ORNITHOPUS, bird's-foot, in botany, a genus of plants producing papi-

lionaceous flowers; the vexillum is cordated and intire; the alæ are ovate and erect, and almost as large as the vexillum; the carina is very small and compressed: the fruit is a taper subulated pod, with several articulations, and containing in each joint a single roundish seed.

The leaves of a species of this genus, are said to be good for an hernia, and for breaking and expelling the stone of the kidneys or bladder.

OROBANCHE, broom-rape, in botany, a genus of plants, the corolla of which is monopetalous and ringent; and its fruit is an oblong capsule formed of two valves, and containing a great many minute seeds.

The leaves of this plant, dried, and reduced to a powder, afford great relief in extreme pains of the cholic; and its syrup is recommended against the hypochondriac affection.

OROBANCHOIDES, a plant called by Linnaeus monotropa. See the article MONOTROPA.

OROBUS, bitter-vetch, in botany, a genus of plants producing papilionaceous flowers; the vexillum is heart-shaped; the alæ are oblong and connivent; the carina is bifid and ascendent: the fruit is a long taper pod, ending in a point, having one cell, which contains a number of roundish seeds.

It agrees in virtues with ervum. See the article ERVUM.

ORONTIUM, in botany, a genus of plants, whose flower-cup is a cylindric spadix; the corolla is formed of six peltated, roundish, persistent petals, with six short sword-shaped filaments, topped with oblong twin antheræ: the fruit is a thin follicule, containing a fungous roundish seed.

ORPELLO, in the glass-trade, calcined glass reduced to a black powder.

ORPHAN, a fatherless child, or minor; or one that is deprived both of father and mother.

ORPIMENT, *Auripigmentum*, in natural history, a fossile substance usually found in copper-mines, composed of thin flakes, like the talcs; which easily split, and are flexible, and not elastic, soluble in oil, fusible in a moderate fire, and yielding in burning an offensive smell like garlic.

It is an excellent depilatory mixed with lime, and made into a paste with water; and the painters are fond of it as a gold-colour.

ORPINE, *Anacampteros*, in botany, a plant whose root is perennial, composed of several white fleshy tubercles, from which arise several upright, round, succulent stalks, about two feet high, branching out at the top; the leaves are fleshy, oval, oblong, of a blueish-green colour, and serrated on their edges near the extremity: the flowers are placed on the top of the stalks in a corymbus, they are rosaceous, and are either of a white or purple colour: their form and generative parts are like those of sedum. See the article SEDUM.

Orpine is accounted vulnerary and astringent, and

and is much recommended for its virtue in easing of pains; the leaves bruised and laid on the part, produce this effect, both in green-wounds and putrid ulcers; and if applied to corns, will in a short time take them away.

*ORPINE of Imperatus.* See the article *TELEPHIUM*.

*Lesser ORPINE.* See the article *CRASSULA*.

*ORRACH*, four kinds, in botany. See the articles *ATRIPLEX*, *BLITUM*, *ATRAPHAXIS*, and *CHENOPODIUM*.

*ORRERY*, a curious machine, or movement, for representing the motions and appearances of the heavenly bodies. See plate *LXXII. fig. 5.*

The orrery, or planetarium, is fixed in a frame of ebony, contained by twelve vertical planes, on which are represented the twelve signs of the zodiac. The upper surface is flat, of polished brass, on whose outward circumference are screwed in twelve brass pillars, which support a large flat silvered ring, marked 12, representing the ecliptic, with several circles drawn upon it. The three innermost are divided into twelve parts for the signs of the zodiac, each of which is divided into thirty degrees, and among these degrees are graven in their proper places, the nodes, aphelia, and greatest north and south latitudes of the planets. Between the next two circles are the cardinal points. The next three circles have the months and days of the month, according to the new stile. Upon the brass surface of the machine are graduated silver circles, which carry the planets (represented by silver balls) upon arbors or stems, that raise them up to the height of the plane of the ecliptic; and turning about the handle or winch of the orrery, all the planets move at their proportional distances from a little gilt ball in the middle, which represents the sun; and perform their revolutions according to their periodical times. There are fixed indices of blued steel, which shew the longitudes of the planets, by pointing to the divisions of the silvered rings or circles, as they move round. But as these circles, being concentric, give only the mean distances, the true orbits, according to their excentricities, are graven on the outside of each circle, with the periodical times taken from the tables, to shew what the revolutions are, nearer than can be performed by any machine. The nodes and aphelia, with the places of the greatest north and south latitudes, are also marked on those orbits.

In the middle of this large circle, designed to represent the ecliptic, is fixed a globe 1. to represent the sun; next the sun is a small ball, 2, to represent Mercury; next to this is Venus, represented by a larger ball, 3; and, at a greater distance from the sun, you see the earth, 4, represented by an ivory ball, surrounded, at some distance, by a ring, which expresses the orbit of the moon, making an angle with the circle that represents the ecliptic, and

thereby shewing the inclination that they have to each other in the heavens, and also the line of the nodes. Within the same ring is another ivory ball, 5, with a black cap or case, to represent the moon; the cap is contrived always to cover that hemisphere, which is turned from the sun, and thereby distinguisheth the enlightened part from the dark side, and, consequently, her age: 6 represents Mars; 7 is Jupiter, attended with his satellites, or four moons; and 8, the outmost of all the planets, is Saturn, with his ring or belt, and five satellites or moons. All these are fixed upon small stems, which severally represent their axes, each of which hath its peculiar and proper inclination to the plane of that circle which represents the ecliptic. 9 is a dial-plate; 10, 10, 10, meridians; 11, the equator; 12, the ecliptic with its circles, already described; 13, 13, two keys, for locking and unlocking the diurnal and annual motions; and as to the arctic circle, tropic of cancer, and moveable horizon, they are named in the figure.

By means of the orrery, a great many persons, who have not time to apply themselves to the study of astronomy, and yet are desirous to be acquainted with the celestial appearances, in a few days may get a competent knowledge of several phaenomena, and especially be cured of the common prejudices against the motion of the earth, and the copernican system. See the article *COPERNICAN*.

But the principal use of the orrery is to render the theory of the earth and the moon easy and intelligible; and to evidence to our senses how all these appearances happen, which depend on the annual or diurnal rotation of the earth, and the monthly revolutions of the moon: as the variety of seasons, the vicissitudes and various lengths of days and nights, the manner of solar and lunar eclipses, the various phases of the moon, &c.

There have been various forms invented for this noble instrument, two of which have principally obtained, viz. the hemispherical orrery, and the whole sphere: though the orrery at first was made without any sphere, with only the sun, the earth, and moon, revolving about it; but as this was too imperfect a state, they soon began to invest it, some with a half sphere, and others with a whole sphere, to be an adequate representation of the solar system.

The hemispherical orrery, as that just described, has been made in greater numbers than any other, on account of their being made much cheaper and easier than those in a sphere of the same size; there being a vast difference between placing an hemisphere on the box of an orrery, and disposing an orrery in a large moveable sphere. But the idea given us by the former, is very imperfect and unnatural in comparison of the latter, and it is surprising to think how they should have had so great a run!

An orrery, therefore, adapted to an armillary sphere,

Sphere, is the only machine that can exhibit a just idea of the true system of the world, with the diurnal and annual motions of the heavenly bodies; but is likewise capable of exhibiting the third motion of the earth, viz. that motion of the earth by which the poles of the world revolve about the poles of the ecliptic, and occasions what is commonly called the precessions of the equinoxes, or more properly the retrogression of the earth's nodes.

As the distances are in their true proportions to each other, so likewise are the bodies of the planets in their just proportions to one another. But it cannot be expected, that the diameters of the planets should be in proportion to the diameters of the orbits; because taking Jupiter under three inches diameter, and the earth a little more than a quarter of an inch, it would require the system to be of the bigness of a mile and  $\frac{3}{4}$ , the orbit of Saturn 9000 feet in diameter, and so on of the rest; which would make the machine 3000 times greater than it is. And if the bodies were suited to the dimensions given, the bodies must be 3000 times less, which would render them all invisible but the sun; and that would be less than  $\frac{1}{1000}$ th part of an inch. For this reason, as a ball big enough to represent the sun cannot be put on, we are to suppose the sun (in respect of them) as big as the inner circle of the silver ring which represents the ecliptic.

As the orbit of the moon, and the orbits of the satellites of Jupiter and Saturn, are quite lost in this proportion of the orbits of the primary planets, much more are the satellites themselves; therefore the satellites are usually not put on in this position of the machine. But Saturn's ring is joined to Saturn's body, according to its proportion, and the inclination of its plane to the plane of Saturn's orbit: and as the planet is carried round, the ring always moves parallel to itself, as it does in the heavens. Thereby we see why the inhabitants of the earth, in one revolution of Saturn, see the ring twice in the most open situation of the ansæ, as at 8, and twice, as if it had no ring, that is, when the edge of the ring is towards the earth (the plane of the ring going through the observer's eye) and the successive increasing and decreasing of the visible bigness of the ansæ.

Jupiter, with his moons, is represented at 7, and the spots whereby his revolution has been observed.

When you have a complete idea of the proportional bigness of the planets, Jupiter and Saturn are taken off, and others put on three times less than the former, in order to put satellites about them, (and at the same time the moon is joined to the earth) and shew how the satellites accompany their primary planet in its course round the sun. These satellites which are pearls upon crooked stems, do not turn by clock-work round their primaries (as has been done in some large orreries) but are only

set by the hand; because, to do it, would be only a needless expence, to give a false notion of their bigness, distances, and inclination of their orbits, in respect of their primaries. But to give a right notion of Jupiter's and Saturn's satellites, there is shewn for each of these planets a system a-part, where the distances from the primary, and the bigness of the satellites, are expressed; and in this system, though Jupiter is but of about an inch diameter, the outermost satelite is as far distant from Jupiter's center, as Saturn is from the sun in the machine; which shews the inconsistency and disproportion of making the satellites to move round Jupiter in an orrery. Saturn's satellites are still more improperly put in; because four of them move in orbits very much inclined to Saturn's ecliptic (viz. in an angle of above thirty degrees) and the fifth has its orbit almost in the same plane as Saturn's ecliptic, with a diameter greater than the diameter of the whole orrery, even when Saturn is three times less than the Saturn of the orrery.

The next thing which is put on, is a contrivance to shew, that all the confusion of the planets-motions in the Ptolemaic hypothesis (called their stations and retrogradations) is not really, but apparently so, in the Capernican or true system of the world. And this is done by two steel indices, one of which being always applied to the sun, and successively to the top of the stem of the planet to be examined, whilst the other is applied to the earth (as a center) and the said planet: by turning the handle of the machine, the heliocentric and geocentric places of the planet are seen on the ecliptic at the same time; shewing why the planets seem to go backwards and forwards when viewed from the earth; they go all the while regularly from east to west, as they would be seen from the sun.

When the machine is put in motion, all these bodies move round that which represents the sun, and, at the same time, both that, and all those which represent such of the planets as have been observed to have a rotation round their axis, turn round upon the said stems, and in their proper times. The satellites, or moons, also revolve about their primaries at the same time; and the ring that represents the orbit of the moon has likewise its proper motion, whereby that of its nodes is also expressed. The whole machine is put into motion by turning a small winch, 14, like the key of a clock, with very little strength. And, above this winch, is a cylindriall pin, which may be drawn a little out, or pushed in at pleasure: when it is pushed in, all the planets, both primary and secondary, will move according to their respective periods, by turning the handle or winch: when it is drawn out, the motions of the satellites of Jupiter and Saturn will be stopped, while all the rest move freely. In the place of the sun, you may fix a brass lamp, with two convex glasses, made on purpose; which, being

ing placed with the glass directly to the earth, and turning round in the same time with the earth, throws a continual strong light upon it and the moon, in whatever part of its orbit it is; and so not only the times in which the eclipses of the sun and moon will happen, are shewn, but the phenomena themselves are truly represented.

When you propose to use this machine, place a small black patch, or a bit of wafer, upon the middle of the sun, right against the first degree of  $\varpi$ : you may also place patches upon Venus, Mars, and Jupiter, right against some noted point in the ecliptic; put on the handle, and push in the pin which is just above it. One turn of this handle answers to a revolution of the ball, which represents the earth, about its axis; and, consequently, to 24 hours of time, as may be seen by the motion of the hour index, 9, which is marked, and placed at the foot of the wire, on which the ball of the earth is fixed: again, when the index has moved the space of ten hours, Jupiter makes one complete revolution round its axis; and so of the rest.

By these means the revolutions of the planets, and their motions round their own axes, will be represented to the eye. And it is worth observation, that the diurnal motion of the planets was discovered, by observing the motions of the spots upon the surface of the sun, and of the planets in the heavens, after the same manner as we here observe the motions of their representatives, by that of the marks placed upon them in this machine.

This machine is so contrived, that the winch may be turned either way; so that, the same number of revolutions being made backwards, they will bring all the planets to their former aspects or situations in respect to each other.

It would be too great an undertaking here to give an account of the mechanism of the larger sort of orreries, which represented the movements of all the heavenly bodies; nor, indeed, can it be done either by diagram or description, to render it intelligible to the most discerning reader; but, instead of that, we shall exhibit an idea of the theory and structure of an useful, concise, and portable planetarium, which any gentleman may have made for a small expence, and will exhibit, very justly, the motions of all the primary planets about the sun, by wheel-work; and those that have secondaries, or moons, may have them placed about their primaries moveable by the hand, so that the whole shall be a just representation of the solar system, or true state of the heavens, for any given time of the year.

In order to this we must compare, and find out the proportion, which the periodical times, or revolutions of the primary planets, bear to that of the earth; and they are such as are expressed in the table below, where the first column is the time of the

earth's period in days and decimal parts; the second that of the planets; the third and fourth are numbers in the same proportion to each other: as,

|                |                                   |
|----------------|-----------------------------------|
| 365,25:88      | $\delta :: 83: 20$ , for Mercury. |
| 365,25:224,7   | $\eta :: 52: 32$ , for Venus.     |
| 365,25:686,9   | $\zeta :: 40: 74$ , for Mars.     |
| 365,25:4332,5  | $\chi :: 7: 83$ , for Jupiter.    |
| 365,25:10759,3 | $\psi :: 5: 148$ , for Saturn.    |

If we now suppose a spindle or arbor with fix wheels fixed upon it in an horizontal position, having the number of teeth in each, corresponding to the numbers in the third column, viz. the wheel A M (*fig. 6.*) of 83 teeth, B L of 52, C K of 50, (for the earth), D I of 40, E H of 7, and F G of 5; and another set of wheels moving freely about an arbor, having the number of teeth in the fourth column, viz. A N of 20, B O of 32, C P of 50, (for the earth), D Q of 75, E R of 83, and F S of 148; then if these two arbors of fixed and moveable wheels are made of the size, and fixed at the distance from each other, as here represented in the scheme, the teeth of the former will take those of the latter, and turn them very freely, when the machine is in motion.

These arbors, with their wheels, are to be placed in a box, of an adequate size, in a perpendicular position: the arbor of fixed wheels to move in pivots at the top and bottom of the box; and the arbor of moveable wheels to go through the top of the box, to a proper height, on the top of which is to be placed a round ball, gilt with gold, to represent the sun. On each of the moveable wheels is to be fixed a socket, or tube, ascending above the top of the box, and having on the top a wire fixed, and bent at a proper distance into a right angle upwards, bearing on the top a small round ball, representing its proper planets.

If then on the lower part of the arbor of fixed wheels be placed a pinion of screw-teeth, a winch turning a spindle with an endless screw, playing in the teeth of the arbor, will turn it with all its wheels; and those wheels will move the others about with their planets, in their proper and respective periods of time, very exactly. For, while the fixed wheel C K moves its equal C P once round, the wheel A M will move A N a little more than four times round, and so will nicely exhibit the motion of Mercury; and the wheel F G will turn the wheel F S about  $\frac{1}{29.5}$  round, and so will truly represent the motion of Saturn; and the same is to be observed of all the rest.

ORRICE, the iris-root. See the article IRIS.

ORTEGIA, in botany, a genus of plants, whose flower is apetalous; it consists of a pentaphyllous upright cup, which is premanent; with three subulated filaments, topped with linear, compressed

pressed antheræ. The fruit is a three-cornered, ovate, unilocular capsule, containing a great number of very minute seeds.

ORTEIL, in fortification, the same with berme. See the article BERME.

ORTHODOX, in church-history, an appellation given to those who are found in all the articles of the Christian faith.

ORTHOGONAL, in geometry, the same with rectangular.

ORTHOGRAPHIC *Projection of the Sphere*, that wherein the eye is supposed at an infinite distance; so called because the perpendiculars from any point of the sphere, will all fall in the common intersection of the sphere with the plane of the projection. See PROJECTION and MAP.

ORTHOGRAPHY, that part of grammar, which teaches the nature and affections of letters, and the just method of spelling or writing words with all the proper and necessary letters, making one of the four greatest divisions or branches of grammar.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore-right plan of any object, and of expressing the heights or elevations of each part. It is called orthography, from its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

This orthography is either external or internal. The external orthography is taken for the delineation of an external face or front of a building; or, as it is by others defined, the model, platform, and delineation of the front of a house, that is contrived, and to be built, by the rules of geometry, according to which pattern the whole fabric is erected and finished. This delineation or platform exhibits the principal wall, with its apertures, roof, ornaments, and every thing visible to an eye placed before the building. Internal orthography, which is also called a section, is a delineation or draught of a building, such as it would appear were the external wall removed.

ORTHOGRAPHY, in perspective, is the fore-right side of any plane, i. e. the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

Lamy, and others, use the word scenography in the same sense.

ORTHOGRAPHY, in fortification, is the profile or representation of a work; or a draught so conducted, as that the length, breadth, height, and thickness of the several parts are expressed, such as they would appear if perpendicularly cut from top to bottom. See FORTIFICATION.

ORTHOPNOEA, in medicine, a species or degree of asthma, where there is such a difficulty of

respiration, that the patient is obliged to sit or stand upright, to be able to breathe. See the article ASTHMA.

ORTIVE, in astronomy, the same with eastern: the ortive or eastern amplitude, is an arch of the horizon intercepted between where a star rises, and the east point of the horizon, or point where the horizon and equator intersect.

ORVALA, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is the length of the cup; the upper lip is oblong, fornicated, and dentated on the top, and the lower one is cut into three segments: there is no pericarpium, but the cup contains four reniform seeds.

ORYZA, rice, in botany, a genus of plants, of which there is but one known species: it hath a root like that of wheat; the stalks are furrowed, rising to two or three feet high, and jointed; the leaves are lanceolated and fleshy; the flowers grow on the tops of the stalks in panicles, they are of a purple colour, and are each formed of a bivalvular glume, with two obtuse premanent valves for its corolla; the nectarium is composed of two leaves, plane, very small, and placed on the side of the germen; there is no pericarpium; the corolla grows to the seed, which is large, oblong, and compressed.

This plant is much cultivated in hot countries, in moist, marshy land, and is used instead of bread in most of the eastern countries, where it is the principal food. It is now planted in great abundance in Carolina, and is as good as in any other part of the world. It is chiefly used here for puddings, and to make rice-milk.

OSCILLATION, in mechanics, the vibration, or reciprocal ascent and descent of a pendulum. See PENDULUM.

OSIER, in botany, a species of the salix or willow, much cultivated in moist places, called osier-grounds, for the use of basket-makers; no plant being more pliant for their purpose: they are propagated by cuttings, and are annually cut down, and always kept low: the season for planting the cuttings is in February, and for cutting the twigs in winter.

OSMITES, in botany, a genus of plants, producing compound and radiated flowers: the flowers which compose the disc are hermaphrodite, tubulose, and quinquifid; the female flowers which form the rays, are lanceolated and intire; it hath no pericarpium, but the cup, which is immutable, contains solitary oblong seeds with very little down.

OSMUNDA, flowering fern, in botany, a genus of the cryptogamia class of plants; it produces on the top of the leaves a globose capsule, disposed in a racemus, and opens horizontally: the seeds are numerous, very small, and of an oval figure: It grows in moist places in several parts of England; the root is the only part used in medicine, and is said to be detergent and sub-astringent.

**OSSICLE**, *ossiculum*, a little bone, a diminutive of bone, in which sense it is frequently used by anatomists.

Botanists also use *ossiculum* for the stone of a plumb, cherry, or any other stone-fruit.

**OSSIFICATION**, the formation of bones, but more particularly the conversion of parts naturally soft, to the hardness and consistence of bones.

**OSTEOCOPOS**, in medicine, any pain in the bones, whether arising from weariness, a sharp scorbutic humour, or a venereal taint. See the article **PAIN**.

**OSTEOSPERMUM**, in botany, a genus of plants, producing compound, radiated flowers; the corollulæ, which form the disc, are hermaphrodite, tubulose, and quinque-dentate: the female florets, which compose the rays, are linear, ligulate, and tridentate; the hermaphrodite flowers are barren, the seeds are hard, globose and solitary, and placed in the cup.

**OSTIA**, in anatomy, an appellation given to the orifices or apertures of the vessels of the body.

**OSTRACISM**, *ostracismus*, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt any thing against the public liberty. It was so called, because the people voted a person's banishment, by writing his name on shells, called in greek *οστρακον*, and casting them into an urn.

**OSTREA**, the oyster. See the article **OYSTER**.

**OSTRICH**, *Struthio*, in ornithology, a distinct genus of birds, of the order of the gallinæ: it has only two toes to each foot, and these are both placed forward; and its head is simple, or not ornamented with the appendages, which are common to most birds of this order.

The ostrich is the tallest of all the bird kind, measuring seven or eight feet when it stands erect: its legs are very long and naked; and the structure of the foot, having only two toes, is particular.

**OSYRIS**, poet's rosemary, in botany, a genus of plants, producing male and female apetalous flowers on different plants. The fruit is an umbilicated, globose berry, with one cell, containing an ossaceous round seed.

**OTHONNA**, African ragwort, in botany, a genus of plants, producing compound, radiated flowers: the hermaphrodite florets, which compose the disc, are tubulous and quinque-dentate; the female corollulæ, which form the rays, are lanceolate, ligulate, indented at the extremity in three parts, which are reflexed. The seeds, which are solitary and oblong, are contained in the cup, and are either naked, or crowned with down.

**OTIS**, the bustard, in ornithology, makes a distinct genus of birds, of the order of the gallinæ, the characters of which are these: there are three

toes on each foot, all turned forwards; and the head is naked, or has no comb.

The bustard has been confounded with the turkey: it is about the size of the common peacock, and runs at a prodigious rate, being frequently taken with greyhounds in a fair course, in the manner of hunting the hare: its flesh is well tasted.

**OTTER**, *Lutra*, in zoology, a genus of quadrupeds, of the order of the ferae, the characters of which are these: the foreteeth of the upper-jaw are straight, distinct, and acute; those of the under jaw are obtuse, and stand close together. the ears are situated lower than the eyes, and the feet are furnished each with five toes, and are palmated or formed for swimming.

Of this genus there are two species: 1. The common otter, with all the toes of an equal length: this is a very fierce animal, three feet in length, including the tail. 2. The Brazilian otter, with the inner toe shorter than all the rest. This is somewhat larger than the former species.

**OVAL**, an oblong, curvilinear figure, otherwise called ellipsis. See **ELLIPSIS**. However, the proper oval, or egg-shape, differs considerably from that of the ellipsis, being an irregular figure, narrower at one end than at the other: whereas the ellipsis, or mathematical oval, is equally broad at each end: though, it must be owned, these two are commonly confounded together; even geometicians calling the oval a false ellipsis.

**OVARIES**, in anatomy, called, by the earlier writers, testes muliebres, are two bodies of nearly an oval figure; but gibbous on the upper surface, and flat below: they are of a whitish colour and smooth surface, and are annexed, one on each side, to the fundus of the womb.

**OVATION**, in the Roman antiquity, a lesser triumph, allowed to commanders for victories won without the effusion of much blood; or, for defeating a mean and inconsiderable enemy. The show generally began at the Albanian mountain, whence the general, with his retinue, made his entry into the city on foot, with many flutes or pipes sounding in concert as he passed along, and wearing a garland of myrtle as a token of peace. The term ovation, according to Servius, is derived from *ovis*, sheep, because on this occasion the conqueror sacrificed a sheep, as in a triumph he sacrificed a bull.

**OVEN**, a kind of domestic furnace, used for baking bread, pies, tarts, &c. of a circular structure, with a very low roof, well lined, both on the top, bottom, and sides, with stone; it has a small entrance in the front, which is exactly fitted by a kind of door, which being clapped to the mouth of the oven, confines the heat, while bread, pies, or puddings are baking. Over this, pastry-cooks, &c. have another oven built much in the same manner, which

which is used for such things as require a less degree of heat.

**Affaying OVEN**, in metallurgy, a particular kind of furnace, used by assayers in their operations upon metals.

**OVER**, in general, signifies one thing being above another; through, or from, one end to another; beyond, cross, or overthwart; it also denotes excess, &c. thus,

**OVER-BLOW**, among seamen, is when the winds blow so very hard, that the ship can bear no top-sails.

**OVER-DONE**, in the manege: a horse is said to be over-done when his wind and strength are broke and exhausted with fatigue.

**OVER-FLOWING of Lands**, among husbandmen, is commonly effected by diverting the streams of rivers, brooks, land-floods, or springs, or some part of them, out of their natural channel; but where streams lie too low for this, they are made use of to turn such engines as may raise a quantity of water to do it. The most useful engine for this purpose is the Persian wheel. See the article **PERSIAN WHEEL**.

**OVER-HALE**, in the sea-language. A rope is said to be over-haled, when drawn too stiff, or haled the contrary way.

**OVER-RULING an Objection**, in law, is the rejecting it, or setting it aside by the court.

**OVER-RUNNING**, among printers. See the article **PRINTING**.

**OVERSEERS of the Poor**, are public officers appointed by statute in every parish, to provide for the poor therein; and sometimes there are two, three, or four, according to the largeness of parishes.

**OVERSET**, or **OVERTHROW**, in the sea-language. A ship is said to overset, when her keel turns uppermost; which misfortune is occasioned either by bearing too much sail, or by grounding her so that she falls upon one side.

**OVERT**, the same with open: thus an overt-act signifies an act which, in law, must be clearly proved; and such is to be alledged in every indictment for high treason.

**OVERTURE**, or **OVERTURE**, opening or prelude; a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, concert of music, &c.

The overture of the theatre, or scene, is a piece of music usually ending with a fugue; the overture of a jubilee is a general procession, &c.

**OVIEDA**, in botany, a genus of plants, the corolla whereof is a ringent single petal; the tube of the corolla is very long and small; the upper-lip is concave and emarginated; the lower one is divided into three equal segments. The fruit is a globose berry, containing two roundish seeds.

**OVIPAROUS**, a term applied to such animals as bring forth their young, *ab ovo*, from eggs; as birds, insects, &c. See the article **EGG**.

**OVIS**, the sheep, in zoology. See the article **SHEEP**.

**OUNCE**, *Uncia*, a little weight, the sixteenth part of a pound-avoirdupois, and the twelfth part of a pound-troy: the ounce-avoirdupois is divided into eight drams, and the ounce-troy into twenty penny-weights. See **WEIGHT**.

**OVOLO**, or **OVUM**, in architecture, a round moulding, whole profile, or sweep, in the Ionic and Composite capitals, is usually a quadrant of a circle: whence it is also commonly called the quarter-round. It was usually enriched with sculpture by the ancients, in the form of chestnut-shells; whence Vitruvius, and others, called it echinus, i. e. chestnut-shell. See the article **MOULDING**.

Among us, it is usually cut with the representation of eggs and anchors, or arrow-heads placed alternately.

**OUT-HOUSES** are such as belong and are adjoining to dwelling-houses.

**OUT-LAND**, among the Saxons, was that land that lay beyond the demesnes, and was granted out to tenants; though at the will of the lord, in like manner as copyhold estates.

**OUT-LAW**, signifies one that is deprived of the benefit of the law, and therefore held to be out of the king's protection.

**OUTLAWRY**, is where a person is outlawed, and on that account loses the benefit of a subject.

**OUTLICKER**, in a ship, a small piece of timber made fast to the top of the poop, and standing out right a-stern. At the outmost end thereof is a hole, into which the standing part of the sheet is reeved, through the block of the sheet; and then again through another block, which is seized close by the end of this outlicker. It is seldom used in great ships, except the mizen-mast is placed so far aft, that there is not room within-board to hale the sheet flat.

**OUTWARD Flanking-Angle**, or *The Angle of the Tenaille*, in fortification, is comprehended by the two flanking lines of defence. See the article **TENAILLE**.

**OUTWORKS**, in fortification, all those works made without-side the ditch of a fortified place, to cover and defend it.

Outworks, called also advanced and detached works, are those which not only serve to cover the body of the place, but also to keep the enemy at a distance, and prevent his taking advantage of the cavities and elevations usually found in the places about the counterscarp, which might serve them either as lodgments, or as rideaux, to facilitate the carrying on their trenches, and planting their batteries against the place; such are ravelines, tenailles, horn-

horn-works, queue d'arondes, envelopes, crown-works, &c. See the articles RAVELINE, TENAILLE, &c.

OWLER, any person who conveys wool, &c. to the sea-side in the night-time, there to be shipped, contrary to law.

OWSE, among tanners, oaken bark beaten or ground small, to serve in the preparation of leather.

OX, *Bos*, in zoology, makes a genus of quadrupeds. See the article *Bos*.

OXALIS, wood-forrel, in botany, a genus of plants, whose flower is monopetalous, and deeply cut into five obtuse emarginated segments, cohering together by their unguis; the stamina are ten capillary erect filaments, topped with roundish furrowed antheræ. The fruit is a pentagonal capsule, with five cells, containing roundish seeds, which fly out with an elasticity when ripe.

OX-EYE, buphthalmum, in botany. See the article BUPHTHALMUM.

OXGANG, or OXGATE, is generally taken, in our old law-books, for fifteen acres, or as much ground as a single ox can plough in a year.

OXICOCCUS, in botany, a species of vaccinium. See VACCINIUM.

OXYCRATE, *Oxycratum*, in pharmacy, &c. a mixture of vinegar and water, proper to allwage, cool, and refresh: they make fomentations of oxycrate, clysters of oxycrate, &c. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

OXYCROCEUM, in pharmacy, &c. a preparation much used in plasters for fractures, &c. made as follows: take yellow wax, one pound; pitch and galbanum, each half a pound: melt them over a gentle fire; and then add of Venice-turpentine, myrrh, and olibanum, each three ounces; saffron, two ounces: make them into a plaster.

OXYMEL, in pharmacy, a composition of vinegar and honey.

There are several sorts of oxymel, whereof the simple kind is made by boiling, in a glazed earthen-vessel, and with a gentle fire, two pounds of cla-

rified honey, in a pint of vinegar, to the consistence of a syrup.

The chief compound oxymels, are oxymel of of garlic, and oxymel of squills.

Oxymel of garlic is made thus: take of garlic, sliced, an ounce and an half; caraway-seeds, and sweet-fennel-seeds, of each two drams; of clarified honey, ten ounces; of vinegar, half a pint; boil the vinegar a little while in a glazed earthen vessel, with the seeds bruised; then add the garlic, and cover the vessel: after all is cold, press out the liquor; and, with the heat of a balneum, dissolve in it the honey.

Oxymel of squills is made by boiling three pounds of clarified honey in a quart of vinegar of squills, over a gentle fire, to the consistence of a syrup.

In all the oxymels, a metalline vessel must be avoided, lest it should be corroded by the vinegar.

OYER, in law-books, seems to have been antiently used for what is now called assise. See the article ASSISE.

OYER and Terminer, a commission directed to the judge of assise, and other gentlemen, empowering them to hear and determine all criminal causes, and to try all offenders, whether for treason, felony, or trespass.

OYER of a Deed, a petition to hear and peruse any deed, upon which an action is brought.

OYES, or OYEZ, signifies *hear ye*; and is frequently used by the cryers in our courts, on making proclamation, or to enjoin silence.

OYSTER, or OISTER, *Ostrea*, in ichthyology, a genus of bivalve shell-fish, the lower valve of which is hollowed on the inside, and gibbose without; the upper one is more flat; and both are composed of a multitude of laminæ or crusts, and usually scabrous or rough on the outer surface: some oyster-shells are also furnished with tubercles or spines, and others are deeply furrowed and plicated: the figure of most is roundish, but in some it is quite irregular.

Oyster-shells are accounted drying and abstergent, and, given internally, sudorific.

P.

## P A C

**P** The fifteenth letter, and eleventh consonant of our alphabet; the sound of which is formed by expressing the breath somewhat more suddenly than in forming the sound of *b*: in other respects, these two sounds are very much alike, and are often confounded one with another.

When *p* stands before *t* or *f*, its sound is lost, as in the words *psalms*, *psychology*, *ptolemaic*, *ptisan*, &c. when placed before *b*, they both together have the sound of *f*, as in *philosophy*, *physic*, &c.

As an abbreviature, *P.* stands for *publius*, *pondo*, &c. *PA. DIG.* for *patricia dignitas*; *P. C.* for *patres conscripti*; *P. F.* for *publii filius*; *P. P.* for *propositum*, or *propositum publice*; *P. R.* for *populus Romanus*; *PR. S.* for *prætoris sententia*; and *PRS. P.* for *præfes provinciæ*.

In the Italian music, *P.* stands for *piano*, or softly; *PP.* for *piu piano*, or more softly; and *PPP.* for *pianissimo*, or very softly.

Among astronomers, *P. M.* is used to denote *post meridiem*, or afternoon; and sometimes for *post mane*, or after midnight.

As a numeral, *P.* signifies the same as *Ē*, viz. 400; and with a dash over it, thus *Ḑ*, 400,000.

Among physicians, *P.* denotes *pugil*, or the eighth part of a handful; *P. Æ.* *partes æquales*, or equal parts of the ingredients; *P. P.* signifies *pulvis Patrum*, or the Jesuits-powder; and *ppt.* *præparatus*, prepared.

*PABULUM*, fuel, among natural philosophers and chemists. See the articles *FUEL* and *FIRE*.

*PACE*, *Passus*, a measure taken from the space between the two feet of a man, in walking; usually reckoned two feet and a half, and in some men, a yard, or three feet. See *MEASURE*.

The geometrical pace is five feet; and 60000 such paces make one degree of the equator. See *DEGREE*.

*PACK*, in commerce, denotes a quantity of goods, made up in loads, or bales, for carriage.

## P Æ D

A pack of wool is seventeen stone and two pounds, or a horse's load.

*PACKAGE*, is a small duty of one penny in the pound, paid for all goods not particularly rated.

*PACKERS*, persons whose employment it is to pack up all goods intended for exportation; which they do for the great trading companies and merchants of London, and are answerable if the goods receive any damage through bad packing.

*PACT*, or *PACTION*, *Paſtum*, in law, denotes a contract or agreement between two or more parties. See *CONTRACT*.

*PACTA CONVENTA*, in Poland, are the articles agreed on between the king and the republic, which they mutually oblige each other to observe.

*PADDLE*, in glass-making, an instrument with which the workmen stir about the sand and ashes in the calcar. See the articles *CALCAR* and *GLASS*.

*PADDOC*, or *PADDOC-COURSE*, a piece of ground encompassed with pales or a wall, and taken out of a park for exhibiting races with grey-hounds, for plates, wagers, or the like.

*PADUS*, the bird-cherry, in botany, a genus of plants, whose flower consists of five roundish, concave, patent petals, inserted by their ungues into the edge of the calyx: the fruit is a roundish drupe, inclosing an oval acuminate nut, with rough furrows.

Of this genus, the laurel is a species. See the article *LAUREL*.

The fruit of this plant is recommended to be hung about the neck of children subject to epilepsies. It is of an emollient and heating nature.

*PÆAN*, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph.

*PÆDEROTA*, in botany, a genus of plants, whose flower is monopetalous, subrotated, quadrid, and obtuse: the stamina are two slender filaments, topped with connivent antheræ: the fruit is

an ovate capsule, with two cells, opening at the top, and contains a number of roundish seeds.

PÆDO-BAPTISM, infant-baptism, or that conferred on children. See BAPTISM.

PÆONIA, piony, in botany, a genus of plants, whose flower consists of five large, roundish, concave petals, which spread open, and are narrow towards the base: the filaments are numerous, and topped with oblong quadrangular antheræ: the fruit consists of two oblong, reflexed, hairy capsules, each containing a single cell and one valve, opening longitudinally inwards: the seeds are numerous, oval, smooth, shining, and coloured: the number of the germina (though naturally two) varies greatly, for in some flowers there are five, but there are always the same number of capsules as germina.

The double flowering piony, is kept in our gardens, for the beauty of its large red flowers; they are easily propagated by parting their roots, in August or September, and are extremely hardy, for they will grow in any soil or situation.

A species, called the male piony, is principally used in medicine, and is said to be a specific against the falling-sickness, convulsions, and the palsy.

PAGAN, *Paganus*, a heathen, gentile, or idolator; one who adores false gods. See the article PAGANISM.

PAGANALIA, certain festivals observed by the ancient Romans, in the month of January.

They were instituted by Servius Tullius, who appointed a certain number of villages (*pagi*) in each of which an altar was to be raised for annual sacrifices to their tutelar gods; at which all the inhabitants were to assist, and give presents in money, according to their sex and age, by which means the number of country-people was known.

The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

PAGANISM, the religious worship and discipline of Pagans, or the adoration of idols and false gods. See IDOLATRY.

The gods of paganism were either men, as Jupiter, Hercules, Bacchus, &c. or fictitious persons, as Victory, Fame, Fever, &c. or beasts, as in Egypt, Crocodiles, Cats, &c. or, finally, inanimate things, as Onions, Fire, Water, &c.

PAGE, a youth of state retained in the family of a prince or great personage, as an honourable servant, to attend in visits of ceremony, do messages, bear up trains, robes, &c. and at the same time to have a genteel education, and learn his exercises.

The pages in the king's household are various, and have various offices assigned them, as pages of honour, pages of the presence-chamber, pages of the back stairs, &c.

This word is used in the Turkish seraglio for the children of tribute, or slaves who wait on the grand seignior: they are commanded by the chief aga, and constitute four classes, called oda's.

PAGEANT, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shews, processions, &c.

PAGOD, or PAGODA, a name whereby the East-Indians call their temple in which they worship their gods.

PAGOD, or PAGODA, is also the name of a gold and silver coin, current in several parts of the East-Indies.

PAIN, *Dolor*, is defined to be an uneasy sensation, arising from a sudden and violent solution of the continuity, or some other accident, in the nerves, membranes, muscles, vessels, &c. of the body; or, according to some, it consists in a motion in the organs of sense; and according to others, it is an emotion of the soul occasioned by these organs.

PAINTED-LADY, pink, in botany. See the article PINK.

PAINTED LADY, pea, in botany. See the article LATHYRUS.

PAINTING, the art of representing natural bodies, and giving them an appearance of life, by the turn of lines, and the degrees of colours.

Whoever would apply himself to painting, says that celebrated Italian painter Leonardo da Vinci, must in the first place learn perspective; this will enable him to dispose things in their proper places, and to give the due dimensions to each: having done this, he must learn to design; choosing for that purpose some able master, who at the same time may give him some insight into the colours of figures: he ought then to consult nature, to confirm himself in what he has already learnt, and, lastly, let him apply himself to the study and imitation of the greatest masters, in order to get a habit of reducing what he has learnt into practice. See the articles DRAWING, DESIGN, PERSPECTIVE, &c.

For the different methods of painting, see the articles ENAMEL, FRESCO, GLASS, LIMNING, MINIATURE, &c.

PAIR, *Par*, denotes two equal and similar things joined together, either collectively, as a pair of gloves, or two similar parts that compose one whole, or a set of things joined to make another complete, &c.

PAIR, in anatomy, an assemblage or conjugation of two nerves, which have their origin together in the brain, or spinal marrow, and thence distributed into the several parts of the body, the one on one side, and the other on the other.

PALACE, *Palatium*, a name generally given to the dwelling-houses of kings, princes, and other great personages; and taking different epithets, according to the quality of the inhabitants, as imperial palace, royal palace, pontifical palace, cardinal palace, ducal palace, episcopal palace, &c.

PA-

**PALANQUIN**, a kind of chaise, or chair, borne by men on their shoulders, much used by the people of China, and the east, as a vehicle for their easy conveyance from place to place.

**PALATE**, *Palatum*, in anatomy, the flesh that composes the roof, or the upper and inner part of the mouth. See **MOUTH**.

**PALE**, *Palus*, a little pointed stake or piece of wood, used in making inclosures, separations, &c.

The pale was an instrument of punishment and execution, among the ancient Romans, and still continues so among the Turks. Hence, empaling, the passing a sharp pale up the fundament through the body.

**PALE**, in heraldry, one of the honourable ordinaries of an escutcheon; being the representation of a pale, or stake, placed upright, and comprehending the whole height of the coat from the top of the chief to the point.

**PALED FLOWERS**, in botany, are those which have their leaves set about, or surrounding, a head or thrum, as in marigolds, &c.

**PALES**, or **PILES**, in carpentry, denote rows of stakes driven deep into the ground to make wooden bridges over rivers; they serve to support the beams laid across them, from one row to another, and are strongly bound with cross-pieces.

**PALILICIUM**, in astronomy, the star called the bull's-eye, or aldebaran. See the article **ALDEBARAN**.

**PALING**, a sort of fencing for fruit-trees planted in fields, wherein three small posts are erected at a foot and a half distance one from another, and near the top nailed to each other with cross-bars.

In fixing the pales in form of a triangle, room is to be left for the tree to play and bow by the high winds, without galling: the trees are to be bound to a stake for a year or two, after which, fern or straw may be stuffed in betwixt the tree and the uppermost rails to keep it upright.

If the place be open to deer, rabbits, or the like, a post is to be nailed to the bar between every two pales.

**PALISADE**, or **PALISADO**, in fortification, an inclosure of stakes or piles driven into the ground, each six or seven inches square, and eight feet long, three whereof are hid under-ground.

*Turning-PALISADES*, an invention of M. Coehorn, in order to preserve the palisades of the parapet of the covert-way from the besiegers shot.

He orders them so, that as many of them as stand in the length of a rod, or in about ten feet, turn up and down like traps, so as not to be in sight of the enemy till they just bring on their attack, and yet are always ready to do the proper service of palisades.

**PALISADE**, in gardening, denotes a sort of ornament; being a row of trees which bear branches and leaves from the bottom, cut and spread in man-

ner of a wall along the side of an alley, or the like, so as to appear like a wall covered with leaves.

**PALISSE**, in heraldry, a bearing like a range of palisades before a fortification, represented on a fesse, rising up a considerable height, and pointed at top, with the field appearing between them.

**PALIURUS**, Christ's-thorn, in botany, a plant which grows naturally in Palestine; it rises with a pliant shrubby stalk, to the height of eight or ten feet, sending out many weak slender branches, armed with thorns, garnished with oval leaves placed alternately, standing upon foot-stalks near an inch long, these have three longitudinal veins, and are of a pale green; the flowers come out at the wings of the stalk in clusters, almost the length of the young branches; they are of a greenish-yellow colour, and appear in June; they are succeeded by broad, roundish, buckler-shaped seed-vessels, which have borders like the brim of a hat, the foot-stalks being fastened to the middle; these have three cells, containing in each a single seed.

This is by many persons supposed to be the plant from which the crown of thorns, put upon the head of our Saviour, was composed; the truth of which is supported by many travellers of credit, who affirm, that this is one of the most common shrubs in the country of Judea; and from the pliability of its branches, which may be easily wrought into any figure, it may afford a probability.

This shrub also grows wild in most parts of the Levant, also in Italy, Spain, Portugal, and the south of France; it is propagated by sowing its seeds, or by laying down its tender branches in the spring, which will take root in a year's time.

For the generical characters of paliurus, see the article **RHAMNUS**, of which it is held a species by Linnæus.

**PALL**, in heraldry, denotes a kind of cross, representing the pallium, or archiepiscopal ornament sent from Rome to the Metropolitans.

**PALL**, *Pallium*, in matters of dress. See the article **PALLIUM**.

**PALLADIUM**, in antiquity, a statue of the goddess Pallas, supposed to have dropped down from heaven, preserved in Troy, whereon the fate of that city is said to have depended.

**PALLET**, among painters, a little oval table or piece of wood, or ivory, very thin and smooth; on, and round which, the painters place the several colours they have occasion for, to be ready for the pencil.

The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but instead thereof, a hole at one end to put the thumb through to hold it.

**PALLET**, among potters, crucible-makers, &c. a wooden instrument, almost the only one they use, for forming, heating, and rounding their works: they have several kinds, the largest are oval, with a handle;

handle; others are round, or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off whatever is superfluous on the moulds of their work.

**PALLET**, in gilding, an instrument made of a squirrel's tail, to take up the gold-leaves from the pillow, and to apply and extend them on the matter to be gilt.

**PALLET**, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

**PALLET** is also a part belonging to the ballance of a watch or movement. See **WATCH**.

**PALLIATION**, or a **PALLIATIVE CURE**, in medicine, is when, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain, or some other urgent symptoms, as in ulcerated cancers, or cancerous fistulas, and the like.

Palliative indication, is where the symptoms of a disease give too much trouble and danger to have their cure deferred till the disease whereon they depend is removed: here the symptoms themselves are to be cured or mitigated apart.

**PALLIER**, or **PAILLIER**, in building, denotes a landing-place in a stair-case.

**PALLIFICATION**, the strengthening the foundation of any building, by driving piles into the ground. See the articles **PILE** and **FOUNDATION**.

**PALLIUM**, or **PALL**, an archiepiscopal vestment, of white woollen cloth, about the breadth of a border, made round, and thrown over the shoulders.

Upon this border there are two others of the same matter and form, one of which falls down upon the breast, and the other upon the back, each having a red cross upon it; several crosses of the same colour being likewise upon the upper part of it, about the shoulders.

**PALM**, *Palma*, in anatomy, the inside of the hand, called also *vola*. See the articles **HAND** and **PALMARIS**.

**PALM** is also a measure of length. See the article **MEASURE**.

**PALM-SUNDAY**, in the Christian church, the Sunday next before Easter; being so called in memory of our Saviour's triumphal entry into Jerusalem, when the multitude that attended him strewed palm-branches in his way.

**PALM-TREE**, *phoenix*, in botany, &c. See the article **PHOENIX**.

**PALMA CHRISTI**, in botany. See the article **RICCINUS**.

**PALMARIS MUSCULUS**, one of the flexor-muscles of the hand, so called as being inserted into the palm of the hand by a broad expanded tendon:

its office seems to be the constriction of the palm. There is also another muscle of the hand called *pulmaris brevis*, and *quadratus*, in form of a small mass of flesh, which adheres to the aponeurosis of the former muscle, above the abductor muscle of the little finger: it is said to assist in drawing together the hand; but Heister observes, that both these muscles are found wanting in dissections.

**PALMATED**, something resembling the shape of the hand: thus we say palmated leaves, roots, stones, &c.

**PALMETTO**, in botany. See the article **CHAMÆROPS**.

**PALMIPEDES**, among ornithologists, the same with web-footed birds.

**PALMISTRY**, a kind of divination, or rather a deceitful art practised by gypsies, who pretend to foretell future events by looking upon the lines and marks of the hand: it is prohibited by stat. 1 and 2 Phil. and Mar. c. 4.

**PALPABLE**, something perceivable by the senses, particularly that of feeling.

**PALPITATION**, in medicine, a spastic contraction of the heart, when it leaps and beats violently.

**PALSY**, *παραλυσις*, in medicine, a disease where-in the body, or some of its members, lose their motion, and sometimes their sensation or feeling.

This disease never is acute, is often tedious, and in old people almost incurable; and the patient for the most part drags a miserable life. For the vigour of his mind, together with his memory, are lost, or vastly impaired; he totters and shakes, and becomes a dismal sight; as if no longer a man, but an animal half dead.

**PALUMBERIUS**, *accipiter*, the goshawk. See the article **GOSHAWK**.

**PALUMBUS**, the ringdove, a beautiful species of pigeon, with the neck white on each side, and a brown spot behind. See the article **COLOMBA**.

**PALUS MEOTIS**. See **MEOTIS**.

**PALY**, or **PALE**, in heraldry, is when the shield is divided into four or more equal parts, by perpendicular lines falling from the top to the bottom.

**PALY-BENDY** is when the escutcheon is divided by perpendicular lines, which is paly; and also by diagonals, which is called bendy.

**PANACEA**, among physicians, denotes an universal medicine, or a remedy for all diseases; - a thing impossible to be obtained, according to no less an author than Boerhaave.

Some also give the appellation panacea to certain plants, called in English alheals. See the article **ALHEAL**.

**PANADA**, a diet consisting of bread boiled in water to the consistence of a pulp, and sweetened with a little sugar. It is given to young children,

and to sick persons, whose digestion is weak, or where stronger foods would be improper. It is sometimes made thin, to serve as a drink.

**PANAX**, *Ginseng*, in botany. See the article **GINSENG**.

**PANCHYMAGOGUE**, in pharmacy, a name given to some cathartic extracts, that have the reputation of purging off all kinds of humours.

**PANCRATIUM**, in botany, a genus of plants; the characters of its flowers are; the cup is an oblong, obtuse, compressed spathe, opening on the side, and withers; the corolla consists of six lanceolated petals, and a cylindrical, funnel-shaped nectarium, on the outside of which, above the base, the petals are inserted: the stamina are six subulated filaments, inserted in the brim of the nectarium, and topped with oblong prostrate antheræ; the germen is obtuse and trigonal; the style slender, and longer than the stamina, and crowned with an obtuse stigma. The fruit is a roundish three-cornered capsule, formed of three valves, having three cells, which contain a number of globose seeds.

There are several species of the pancratium, which are all bulbous rooted; the most esteemed are the West-Indian kinds; the flowers are large, growing in bunches on the top of the stalks; they are of a pure white, and have a most delightful fragrantcy. These plants require a hot-house to preserve them, and are increased by the off-sets which arise from the root.

**PANCREAS**, in anatomy, popularly called the sweet-bread, is a large gland, of a flattish shape and fleshy colour, extended behind the stomach, and reaching from the duodenum transversely towards the spleen. Its length is eight or nine inches; its breadth about two fingers, or two and a half; its thickness about one finger; and its weight about three ounces. In man, the shape of a pancreas very much resembles the tongue of a dog; it is broadest towards the duodenum, and gradually narrower towards the spleen. Its substance is glandulous, and it seems formed by a conglomeration of many glands. It is surrounded with a membrane, which is contiguous with the peritonæum: it has arteries from the cœliac and ramus splenicus; and veins also from the splenic vein; its nerves are from the par vagum and the intercostals; and, finally, it has an excretory duct, which is situated in the middle of the pancreas, where it resembles an empty vein, and is about the thickness of a small straw. This duct terminates in the duodenum, which it enters obliquely, four or five fingers-breadth below the pylorus, usually at the same orifice with the ductus cholidocus; but sometimes it has a double aperture.

The use of the pancreas is to secrete a peculiar liquor, called the pancreatic juice, which is of a salivose nature, and is carried by the pancreatic duct into the duodenum, where it serves to dilute the chyle, to render it more fluid, and fit to enter the

mouths of the lacteals; and, perhaps, to temper and dilute the bile, to change its viscosity, bitterness, colour, &c. and make it mix with the chyle, in order to reduce the several tastes, odours, and properties of the several foods, into one homogeneous one.

**PANDECTS**, in the civil law, collections made by Justinian's order, of five hundred and thirty-four decisions of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by an epistle prefixed to them. The pandects consisted of fifty books, and make the first part of the body of the civil law.

**PANEGYRIC**, on oration in praise of some extraordinary thing, person, or virtue.

Panegyrics were anciently made in the public and solemn assemblies of the Greeks, either at their games, their feasts, or religious meetings. To render them the more solemn, they used to begin with the praises of the deity, in whose honour the games, &c. were celebrated; then they descended to the praises of the people or country where they were celebrated; then to the princes or magistrates who presided at them; and at length to the champions, especially those who had gained the prize.

Panegyric is ranked among the demonstrative kinds of orations, whereof there are commonly reckoned two kinds, viz. the artificial, where every thing is reduced to certain heads; and the other natural, where the order of history is observed.

**PANEL**, in law, signifies a schedule, or small roll of parchment, in which is contained the names of the jurors returned by the sheriff, to pass upon trial; so that the impanelling of a jury, is no more than the sheriff's entering them upon his panel or roll.

**PANIC**, denotes an ill-grounded terror or fright.

**PANICLE**, in botany, denotes a soft woolly beard, on which the seeds of some plants, as millet, reeds, &c. hang.

**PANICUM**, panic, in botany, a genus of plants, the corolla of which is composed of two oval, acute, pointed valves: the stamina are three short hairy filaments, topped with oblong antheræ: the seed is single and roundish, and inclosed in the corolla.

Panic is cultivated in several parts of Germany, France, and Italy, as corn, for the sustenance of the inhabitants, of which they make cakes or bread; but its nutriment is not reckoned so good as millet.

Panic-seed is accounted drying, refrigerant, and astringent; and therefore recommended in spitting of blood, and nocturnal pollutions.

**PANNEL**, in joinery, is a tympanum, or square piece of thin wood, sometimes carved, framed, or grooved in a larger piece, between two upright pieces and two cross pieces.

**PANNEL**, in masonry, is one of the faces of a hewn stone.

**PANNELS of a Saddle**, are two cushions or bolsters, filled with cow's, deer's, or horse's hair, and placed under the saddle, on each side, to prevent the bows and bands from galling the horse.

**PANNICULUS CARNOSUS**, in comparative anatomy, a robust fleshy tunic, situated in beasts, between the tunic and the fat; by means of which, they can move their skin in whole or part: it is altogether wanting in mankind.

**PANTALOOON**, a sort of garment, consisting of breeches and stockings all of one piece; said to have been first introduced by the Venetians.

In a theatrical sense, pantaloone denotes a buffoon, who performs grotesque dances; and hence is used, by some, for the habit or dress worn by such persons.

**PANTHEA**, in antiquity, statues composed of the figures or symbols of several divinities.

**PANTHEON**, in Roman antiquity, a temple of a circular form, dedicated to all the gods: it was built by Agrippa, son-in-law to Augustus; but is now converted into a church, and dedicated to the Virgin and all the martyrs.

**PANTHER**, *Panthera*, in zoology, the female leopard. See **LEOPARD**.

**PANTOMIME**, in antiquity, a person who imitates all sorts of actions and characters, by mere gestures, without speaking a word.

**PAPAVER**, the poppy, in botany. See the article **POPPY**.

**PAPAW**, *Carica*, in botany, a genus of the dioecia class, producing male and female flowers on different plants; the male flower is monopetalous and infundibuliform, with the limb cut into five parts; the corolla of the female flower is pentapetalous, the petals being lanceolato-linear, obtuse on both sides, very long, erect below the middle, but above the middle bending outwards and downwards. The fruit is a very large, oblong, fleshy berry, angulated with five furrows, having five cells containing a number of small, ovate, furrowed seeds, inclosed in a pulp.

The papaw rises with a thick, soft, herbaceous stem, to the height of eighteen or twenty feet, which is naked till within two or three feet of the top, and hath marks of the vestiges of the fallen leaves great part of its length. The leaves come out on every side of the stem, upon long footstalks; those which are situated undermost are almost horizontal, but those on the top are erect; these leaves are very large, and divide into many lobes, which are deeply sinuated or cut into irregular divisions: the whole plant abounds with a milky acrid juice, which is esteemed good for the ring-worm. The stem of the plant, and also the footstalks of the leaves, are hollow in the middle; the flowers of the male plants are produced from between the leaves

on the upper part of the plant on every side; they have footstalks near two feet long, at the ends of which the flowers stand in loose clusters, each having a separate short footstalk, these are of a pure white, and have an agreeable odour. The flowers of the female papaw also come out between the leaves toward the upper part of the plant upon very short footstalks, sitting close to the stem. The fruit is about the size of a common melon, and are of different forms; some are angular, and compressed at both ends, others are oval or globular, and some pyramidal; the fruit also abounds with the same acrid milky juice as the plants. This fruit, when ripe, is by the inhabitants of the Caribbee islands eaten with pepper and sugar, as melons.

These plants are raised from seeds, but being tender, they require a hot-house to preserve them in this climate.

**PAPER**, *παπυρος*, sheets of a thin matter, made of some vegetable substance.

The materials on which mankind have, in different ages, contrived to write their sentiments, have been extremely various; in the early ages they made use of stones, and tables of wood, wax, ivory, &c. See the article **BOOK**.

Paper, with regard to the manner of making it, and the materials employed therein, is reducible to several kinds; as Egyptian paper, made of the rush papyrus; bark paper, made of the inner rind of several trees; cotton-paper; incombustible paper; and the European paper, made of linen rags.

Linen, or European paper, appears to have been first introduced among us towards the beginning of the XIVth century; but by whom this valuable commodity was invented, is not known. The method of making paper of linen or hempen rags, is as follows: the linen-rags being carried to the mill, are first sorted, then washed very clean in puncheons, whose sides are grated with strong wires, and the bottoms bored full of holes. After this they are fermented, by laying them in heaps, close covered with sack, till they sweat and rot; which is commonly done in four or five days. When duly fermented, they are twisted into handfuls cut small, and thrown into oval mortars, made of well-seasoned oak, about half a yard deep, with an iron plate at bottom, an inch thick, eight inches broad, and thirty long: in the middle is a washing-block, grooved, with five holes in it, and a piece of hair-sieve fastened on the inside: this keeps the hammers from touching it, and prevents any thing going out except the foul water. These mortars are continually supplied with water, by little troughs, from a cistern, fed by buckets fixed to the several floats of a great wheel, which raises the wooden hammers, for pounding the rags in the mortars. When the rags are beaten to a certain degree, called the first stuff, the pulp is removed into boxes, made like

like corn-chandlers bins, with the bottom board assant, and a little separation on the front, for the water to drain away. The pulp of the rags being in, they take away as many of the front-boards as are needful, and press the mass down hard with their hands: the next day they put on another board, and add more pulp, till the box is full: and here it remains mellowing a week, more or less, according to the weather. After this, the stuff is again put into clean mortars, and is beaten a-fresh, and removed into boxes, as before; in which state it is called the second stuff. The mass is beat a third time, till some of it being mixed with fair water, and brewed to and fro, appears like flour and water, without any lumps in it; it is then fit for the pit-mortar, where it is perfectly dissolved, and is then carried to the vat, to be formed into sheets of paper.

But lately, instead of pounding the rags to a pulp with large hammers, as above, they make use of an engine, which performs the work in much less time. This engine consists of a round solid piece of wood, into which are fastened several long pieces of steel, ground very sharp. This is placed in a large trough with the rags, and a sufficient quantity of water. At the bottom of the trough is a plate with steel bars, ground sharp like the former; and the engine being carried round with prodigious velocity, reduces the rags to a pulp in a very short time. It must be observed, that the motion of the engine causes the water in the trough to circulate, and by that means, constantly returns the stuff to the engine. The trough is constantly fed with clean water at one end, while the dirty water from the rags is carried off at the other, through a hole, defended with wire gratings, in order to hinder the pulp from going off with the dirty water.

When the stuff is sufficiently prepared as above, it is carried to the vat and mixed with a proper quantity of water, which they call priming the vat. The vat is rightly primed, when the liquor has such a proportion of the pulp, as that the mould, on being dipped into it, will just take up enough to make a sheet of paper of the thickness required. The mould is a kind of sieve, exactly of the size of the paper to be made, and about an inch deep, the bottom being formed of fine brass wire, guarded underneath with sticks to prevent its bagging down, and to keep it horizontal; and further, to strengthen the bottom, there are large wires placed in parallel lines, at equal distances, which form those lines visible in all white paper, when held up to the light; the mark of the paper is also made in this bottom, by interweaving a large wire in any particular form. This mould the maker dips into the liquor, and gives it a shake as he takes it out, to clear the water from the pulp. He then slides it along a groove to the cocher, who turns out the sheet upon a felt, laid on a plank, and lays another felt on it, and

returns the mould to the maker, who, by this time, has prepared a second sheet, in another mould: and thus they proceed, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a post; and this they do with such swiftness, that, in many sorts of paper, two men make twenty posts, or more, in a day. A post of paper being made, either the maker or coucher whistles; on which four or five men advance, one of whom draws it under the press, and the rest press it with great force, till all the water is squeezed from it; after which it is separated, sheet by sheet, from the felts, and laid regularly one sheet upon another; and having undergone a second pressing, it is hung up to dry. When sufficiently dried, it is taken off the lines, rubbed smooth with the hands, and laid by till sized, which is the next operation. For this they choose a fine temperate day, and having boiled a proper quantity of clean parchment or vellum-shavings, in water, till it comes to a size, they prepare a fine cloth on which they strew a due proportion of white vitriol and rock-allum, finely powdered, and strain the size through it, into a large tub; in which they dip as much paper at once as they can conveniently hold, and with a quick motion give every sheet its share of the size, which must be as hot as the hand can well bear it. After this, the paper is pressed, hung up sheet by sheet to dry; and being taken down, is sorted, and what is only fit for outside-quires, laid by themselves: it is then told into quires, which are folded and pressed. The broken sheets are commonly put together, and two of the worst quires are placed on the outside of every ream or bundle; and being tied up in wrappers, made of the settling of the vat, it is fit for sale.

Paper is of various kinds, and used for various purposes: with regard to colour, it is chiefly distinguished into white, blue, and brown; and with regard to its dimensions, into atlas, elephant, imperial, super-royal, royal, medium, demy, crown, fool's-cap, and pot-paper.

*Blotting-PAPER*, is paper not sized, and into which, ink readily sinks: it is used in books, &c. instead of sand, to prevent blotting; and also by apothecaries for filtering.

*Teint, or Demi-Teint-PAPER*, is a paper used for designing on, and is either blue, brown, or blistered.

*Blistered-PAPER*, is white-paper washed over with a sponge dipped in foot-water. Its use is to save the labour of the crayon, in places which are to be shadowed the same depth as the tint of this paper: as to the light places, they are made with chalk.

*Marbled-PAPER*. See MARBLING.

*PAPIA, or ORVALA*, in botany. See the article ORVALA.

**PAPILIO**, the butterfly, in zoology, a numerous genus of four-winged insects, of the lepidoptera order, distinguished by clavated antennæ.

The butterflies are so numerous, that authors commonly divide them into classes or subdivisions, according to the number of their legs, some having six and others only four legs, under each of which are comprehended a multitude of beautiful species, distinguished by the different colours and variegations of their wings.

**PAPILIONACEOUS**, among botanists, an appellation given to the flowers of certain plants, from their resembling the figure of a butterfly with its wings expanded; they always consist of four petals, the upper one is called the vexillum, or standard; the two petals, which compose the sides, are called the alæ, or wings; and the lowest petal is termed the carina, or keel, which in some flowers is intire, and in others divided into two segments.

All plants bearing papilionaceous flowers, belong to the diadelphia class of Linnæus: such are peas, beans, kidney-beans, vetches, and other legumes.

**PAPILLA**, the nipple of the breast, in anatomy, See **BREAST**.

There are also papillæ of the skin and tongue. See **CUTIS** and **TONGUE**.

**PAPPUS**, in botany, a soft downy substance, adhering to the upper part of the seeds of divers plants, as of thistles, hawkweeds, dandelion, &c. Its use is to spread them when ripe, by sustaining them in the air so that they may be conveyed to a great distance.

**PAPULÆ**, a name used, by several authors, for eruptions on the skin of any sort.

**PAR**, in commerce, signifies any two things equal in value; and in money-affairs, it is so much as a person must give of one kind of specie, to render it just equivalent to a certain quantity of another.

In the exchange of money with foreign countries, the person to whom a bill is payable, is supposed to receive the same value as was paid the drawer by the remitter; but this was not always the case, with respect to the intrinsic value of the coins of different countries, which is owing to the fluctuation in the prices of exchange amongst the several European countries, and the great trading cities.

The par, therefore, differs from the course of exchange in this, that the par of exchange shews what other nations should allow in exchange, which is rendered certain and fixed, by the intrinsic value of the several species to be exchanged: but the course shews what they will allow in exchange; which is uncertain and contingent, sometimes more and sometimes less; and hence the exchange is sometimes above and sometimes under par. See the article **EXCHANGE**.

**PARABLE**, a fable, or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn, by compar-

ing it with something in which the people are more immediately concerned: such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, &c.

Kircher derives the use of parables from the Egyptians. Some make a difference between a parable and a fable; but Grotius and others use the two terms promiscuously.

Parables are certainly a most delicate way of expressing disagreeable truths on the mind, and in many cases have the advantage of a more open reproof, and even of formal lessons of morality: thus Nathan made David sensible of his guilt by a parable; and thus our Saviour, in attacking the prejudices of his countrymen, always spoke to them in parables.

**PARABOLA**, in geometry, a figure arising from the section of a cone, when cut by a plane parallel to one of its sides. See the article **CONIC SECTIONS**.

To describe a parabola in plano, draw a right line AB (plate LXXII. fig. 7.) and assume a point C without it; then in the same plane with this line and point, place a square rule DEF, so that the side DE may be applied to the right line AB, and the other EF turned to the side on which the point C is situated. This done, and the thread FGC, exactly of the length of the side of the rule, EF, being fixt at one end to the extremity of the rule F, and at the other to the point C, if you slide the side of the rule DE along the right line AB, and by means of a pin, G, continually apply the thread to the side of the rule, EF, so as to keep it always stretched as the rule is moved along, the point of this pin will describe a parabola GHO.

Definitions. 1. The right line AB is called the directrix. 2. The point C is the focus of the parabola. 3. All perpendiculars to the directrix, as LK, MO, &c. are called diameters; the points, where these cut the parabola, are called its vertices; the diameter BI, which passes through the focus C, is called the axis of the parabola; and its vertex, H, the principal vertex. 4. A right line terminated on each side by the parabola, and bisected by a diameter, is called the ordinate applicate, or simply the ordinate to that diameter. 5. A line equal to four times the segment of any diameter, intercepted between the directrix and the vertex where it cuts the parabola, is called the latus rectum, or parameter of that diameter. 6. A right line which touches the parabola only in one point and being produced on each side falls without it, is a tangent to it in that point.

**Cartesian PARABOLA**, is a curve of the second order, expressed by the equation  $xy = ax^3 + bx^2 + c + xa$ , containing four infinite legs, viz. two hyperbolic ones tending contrary ways, and two para-

parabolic legs joining them, being the sixty-sixth species of lines of the third order according to Sir Isaac Newton, called by him a trident.

*Diverging PARABOLA*, a name given by Sir Isaac Newton to five different lines of the third order, expressed by the equation  $yy = ax^3 + bx^2 + cx + d$ .

*PARABOLIC CONOID*, in geometry, a solid generated by the rotation of a parabola about its axis: its solidity is  $\frac{1}{2}$  of that of its circumscribing cylinder.

The circles conceived to be the elements of this figure are in arithmetical proportion, decreasing towards the vertex.

A parabolic conoid is to a cylinder of the same base and height, as 1 to 2, and to a cone of the same base and height, as  $1\frac{1}{2}$  to 1. See GAUGING.

*PARABOLIC CUNEUS*, a solid figure formed by multiplying all the DB's (plate LXXII. fig. 8.) into the DS's; or which amounts to the same, on the base APB erect a prism, whose altitude is AS; this will be a parabolical cuneus, which of necessity will be equal to the parabolical pyramidoid, as the component rectangles in one are severally equal to all the component squares in the other.

*PARABOLIC PYRAMIDOID*, a solid figure generated by supposing all the squares of the ordinate applicates in the parabola so placed as that the axis shall pass through all the centers at right angles; in which case the aggregate of the planes will form the parabolic pyramidoid.

The solidity hereof is had by multiplying the base by half the altitude, the reason of which is obvious; for the component planes being a series of arithmetical proportionals beginning from 0, their sum will be equal to the extremes multiplied by half the number of terms.

*PARABOLIC SPACE*, the area contained between any entire ordinate as VV (plate LXXII. fig. 9.) and the curve of the incumbent parabola.

The parabolic space is to the rectangle of the semi-ordinate into the absciss, as 2 to 3; to a triangle inscribed on the ordinate as a base, it is as 4 to 3.

Every parabolical and paraboloidical space is to the rectangle of the semi-ordinate into the absciss, as  $rx y (m + r)$  to  $xy$ ; that is, as  $r$  to  $m + r$ .

*Segment of a PARABOLIC SPACE*, is that space included between two ordinates.

*PARABOLIC SPINDLE*, in gauging; a cask of the second variety is called the middle frustum of a parabolic spindle.

The parabolic spindle is eight-fifteenths of its circumscribing cylinder.

*PARABOLOIDES*, a name given to parabolas of the higher kind, which are algebraic curves.

*PARACENTESIS*, an operation in surgery commonly called tapping.

*PARACENTRIC MOTION*, in astronomy, denotes so much as a revolving planet approaches nearer to, or recedes from the sun, or center of attraction.

*PARACENTRIC Solicitation of Gravity*, is much the same with the centrepetal force.

*PARACLET*, the COMFORTER, a name given to the Holy Ghost. See the article TRINITY.

*PARADE*, the placing any thing to public view, with all its advantages and ornaments.

*PARADE*, in war, is a place where the troops meet to go upon guard, or any other service.

*PARADE*, in fencing, is the action of parrying or turning off any thrust.

*PARADISE*, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

The celestial paradise is that place of pure and refined delight in which the souls of the blessed enjoy everlasting happiness.

*Bird of PARADISE*, *Paradisæa*, in ornithology, a genus of birds of the order of the picæ, the beak of which is of a cultratusubulated form, and acute; the forehead is gibbous, and the two middle feathers are extremely long, and very firm.

*PARADOX*, in philosophy, a proposition seemingly absurd, as being contrary to some received opinion; but yet true in fact.

*PARAGRAPH*, in general, denotes a section or division of a chapter, and in references is marked thus ¶.

*PARALEPSIS*, παραλειψις, in rhetoric, the pretence of passing over a thing, and yet mentioning it by the bye.

*PARALLACTIC*, in general, something relating to the parallax of heavenly bodies. See the article PARALLAX.

*PARALLAX*, παραλλαξις, in astronomy, denotes a change of the apparent place of any heavenly body, caused by being seen from different points of view; or it is the difference between the true and apparent distance of any heavenly body from the zenith.

Thus let AB (plate LXXII. fig. 10.) be a quadrant of a great circle on the earth's surface; A the place of the spectator, and the point V in the heavens the vertex and zenith. Let VNH represent the starry firmament, AD the sensible horizon, in which suppose the star C to be seen, whose distance from the center of the earth is TC. If this star were observed from the center T, it would appear in the firmament in E, and elevated above the horizon by the arch DE; this point E is called the true place of the phenomenon or star. But an observer viewing it from the surface of the earth at A, will see it at D, which is called its visible or apparent place; and the arch DE, the distance between the true and visible place, is what astronomers call the parallax of the star, or other phenomenon.

If the star rise higher above the horizon to M, its true place visible from the center is P, and its apparent place N; whence its parallax will be the arch PN, which is less than the arch DE. The horizontal parallax, therefore, is the greatest; and the higher a star rises, the less is its parallax; and if it should come to the vertex or zenith, it would have no parallax at all: for when it is in Q, it is seen both from T and A in the same line TAV, and there is no difference between its true and apparent or visible place. Again, the farther a star is distant from the earth, so much the less is its parallax: thus the parallax of the star F is only GD, which is less than DE the parallax of C. Hence it is plain, that the parallax is the difference of the distances of a star from the zenith when seen from the center and from the surface of the earth: for the true distance of the star M from the zenith is the arch VP, and its apparent distance VN, the difference between which PN is the parallax.

These distances are measured by the angles VTM, and VAM, but  $VAM - VTM = TMA$ . For the external angle  $VAM = \angle ATM + \angle AMT$ , the two inward and opposite angles; so that AMT measures the parallax, and upon that account is itself frequently called the parallax: and this is always the angle under which the semi-diameter of the earth, AT, appears to an eye placed in the star; and therefore where this semi-diameter is seen directly, there the parallax is greatest, viz. in the horizon. When the star rises higher, the sine of the parallax is always to the sine of the stars distance from the zenith, as the semi-diameter of the earth to the distance of the star from the earth's center: hence if the parallax of a star be known at any one distance from the zenith, we can find its parallax at any other distance.

If we have the distance of a star from the earth, we can easily find its parallax: for on the triangle TAC rectangular at A, having the semi-diameter of the earth, and TC the distance of the star, the angle ACT, which is the horizontal parallax, is found by trigonometry; and on the other hand, if we have this parallax, we can find the distance of the star; since in the same triangle, having AT, and the  $\angle ACT$ , the distance TC may be easily found.

Astronomers therefore, have invented several methods for finding the parallaxes of stars, in order thereby to discover their distances from the earth. However, the fixed stars are so remote as to have no sensible parallax; and even the sun, and all the primary planets, except Mars and Venus when in perigee, are at so great distances from the earth, that their parallax is too small to be observed. In the moon, indeed, the parallax is found to be very considerable, which in the horizon amounts to a degree or more, and may be found thus; in an eclipse of

the moon, observe when both its horns are in the same vertical circle, and at that instant take the altitudes of both horns: the difference of these two altitudes being halved, and added to the least, or subtracted from the greatest, gives nearly the visible or apparent altitude of the moon's center; and the true altitude is nearly equal to the altitude of the center of the shadow at that time. Now we know the altitude of the shadow, because we know the place of the sun in the ecliptic, and its depression under the horizon, which is equal to the altitude of the opposite point of the ecliptic in which is the center of the shadow. And therefore having both the true altitude of the moon and the apparent altitude, the difference of these is the parallax required. But as the parallax of the moon increases as she approaches towards the earth, or the perigæum of her orbit; therefore astronomers have made tables which shew the horizontal parallax for every degree of its anomaly.

The parallax always diminishes the altitude of a phenomenon, or makes it appear lower than it would do, if viewed from the center of the earth; and this change of the altitude may, according to the different situation of the ecliptic and equator in respect of the horizon of the spectator, cause a change of the latitude, longitude, declination and right-ascension of any phenomenon, which is called their parallax.

The parallax, therefore, increases the right and oblique ascension; diminishes the descension; diminishes the northern declination and latitude in the eastern part, and increases them in the western; but increases the southern both in the eastern and western part; diminishes the longitude in the western part, and increases it in the eastern. Hence it appears, that the parallax has just opposite effects to refraction. See the article REFRACTION.

*Annual PARALLAX*, the change of the apparent place of a heavenly body, which is caused by being viewed from the earth in different parts of its orbit round the sun. See the article EARTH.

The annual parallax of all the planets is found very considerable, but that of the fixed stars is imperceptible. See STAR.

*PARALLAX*, in levelling, denotes the angle contained between the line of the true level, and that of the apparent level.

*PARALLEL*, in geometry, an appellation given to lines, surfaces and bodies every where equidistant from each other; and which though infinitely produced would never meet.

*PARALLEL PLANES*, are such planes as have all the perpendiculars drawn betwixt them equal to each other.

*PARALLEL RAYS*, in optics, are those which keep at an equal distance from the visible object to the eye, which is supposed to be infinitely remote from the object.

**PARALLEL RULER**, or **PARALLELISM**, an instrument consisting of two wooden, brass, &c. rulers, equally broad every where; and so joined together by cross blades as to open to different intervals, accede and recede, and yet still retain their parallelism.

**PARALLELS**, or *Parallel Circles*, in geography, called also parallels or circles of latitude, are lesser circles of the sphere, conceived to be drawn from west to east, through all the points of the meridian, commencing from the equator to which they are parallel, and terminating with the poles.

They are called parallels of latitude, because all places lying under the same parallel, have the same latitude.

**PARALLELS of Latitude**, in astronomy, are lesser circles of the sphere parallel to the ecliptic, imagined to pass through every degree and minute of the colures.

They are represented on the globe by the divisions on the quadrant of altitude, in its motion round the globe, when screwed over the pole of the ecliptic.

**PARALLELS of Altitude**, or **ALMUCANTARS**, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, having their poles in the zenith.

**PARALLELS of Declination**, in astronomy, are the same with parallels of latitude in geography.

**PARALLEL Sphere**, that situation of the sphere, wherein the equator coincides with the horizon, and the poles with the zenith and nadir. See the article **SPHERE**.

**PARALLEL Sailing**, in navigation, is the sailing under a parallel of latitude.

**PARALLELEPIPED**, or **PARALLELOPIPED**, in geometry, a regular solid comprehended under six parallelograms, the opposite ones whereof are similar, parallel and equal.

All parallelepipeds, prisms, cylinders, &c. whose bases and heights are equal, are themselves equal.

A diagonal plane divides a parallelepiped into two equal prisms; so that a triangular prism is half a parallelepiped upon the same base, and of the same altitude.

All parallelepipeds, prisms, cylinders, &c. are in a ratio compounded of their bases and altitudes; wherefore, if their bases be equal, they are in proportion to their altitudes; and conversely.

All parallelepipeds, cylinders, cones, &c. are in a triplicate ratio of their homologous sides, and also of their altitudes.

Equal parallelepipeds, prisms, cones, &c. reciprocate their bases and altitudes.

**PARALLELISM**, the situation or quality whereby any thing is denominated parallel. See the article **PARALLEL**.

**PARALLELISM of the Earth's Axis**, in astrono-

my, that situation of the earth's axis, in its progress through its orbit, whereby it is still directed towards the pole-star; so that if a line be drawn parallel to its axis, while in any one position, the axis, in all other positions, will be always parallel to the same line.

This parallelism is the result of the earth's double motion, viz. round the sun, and round its own axis; or its annual and diurnal motion; and to it we owe the vicissitudes of seasons, and the inequality of day and night. See the article **EARTH**.

**PARALLELOGRAM**, in geometry, a quadrilateral right-lined figure, whose opposite sides are parallel and equal to each other. It is generated by the equable motion of a right line always parallel to itself. When it has all its four angles right, and only its opposite sides equal, it is called a rectangle or oblong. When the angles are all right, and the sides equal, it is called a square. If all the sides are equal, and the angles unequal, it is called a rhombus or lozenge: and if the sides and angles be unequal, it is called a rhomboides.

**PARALOGISM**, in logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false; or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

A paralogism differs from a sophism in this, that the sophism is committed out of design and subtlety, and the paralogism out of mistake and for want of sufficient light and application. See **SOPHISM** and **DEMONSTRATION**.

**PARALYSIS**, the palsy. See **PALSY**.

**PARALYTIC**, a person afflicted with the palsy. See the article **PALSY**.

**PARAMETER**, in conic sections, a constant line, otherwise called latus rectum. See the articles **ELLIPSIS**, **HYPERBOLA**, and **PARABOLA**.

The parameter is said to be constant, because in the parabola, the rectangle under it and any absciss is always equal to the square of the corresponding semi-ordinate; and in the ellipsis and hyperbola, it is a third proportional to the conjugate and transverse axis.

**PARAMOUNT**, in law, signifies the supreme lord of the fee. See **FEE**.

**PARAPET**, in fortification, an elevation of earth designed for covering the soldiers from the enemies cannon or small shot. The thickness of the parapet is from eighteen to twenty feet; its height is six feet on the inside, and four or five on the outside. It is raised on the rampart, and has a slope above called the superior talus, and sometimes the glacis of the parapet. The exterior talus of the parapet is the slope facing the country; there is a banquette or two for the soldiers who defend the parapet to mount upon, that they may the better

discover the country, fosse, and counterscarpe, and fire as they find occasion. See the articles GLACIS, TALUS, BANQUETTE, &c.

Parapet of the covert way, or corridor, is what covers that way from the sight of the enemy, which renders it the most dangerous place for the besiegers, because of the neighbourhood of the faces, flanks, and curtains of the place.

PARAPET is also a little wall raised breast-high on the banks of bridges, keys, or high buildings, to serve as a stay, and prevent people's falling over.

PARAPHIMOSIS, in medicine, a disorder of the penis, wherein the prepuce is shrunk, and withdrawn behind the glands, so as not to be capable of being brought to cover the same; which generally happens in venereal disorders. See the article PREPUCE, &c.

PARAPHRASE, *παρρησιας*, an explanation of some text, in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject; such are esteemed Erasmus's paraphrase on the New Testament, the Chaldee paraphrase on the Pentateuch, &c.

PARAPHROSINE, a word used by medical writers to express a delirium, or an alienation of mind in fevers, or from whatever cause.

PARAPLEGIA, or PARAPLEXIA, in medicine, a species of paralysis, or palsy, usually succeeding an apoplexy. See PALSY.

PARASELENE, in physiology, a mock moon, a meteor, or phenomenon, encompassing or adjacent to the moon, in form of a luminous ring; wherein are observed one, sometimes two, apparent images of the moon.

The paraseleenes are formed after the same manner as the parhelia, or mock suns. See the article PARHELIUM.

PARASITE, *παρσιτος*, among the Greeks, was originally a very reputable title; the parasites being a kind of priests (at least ministers) of the gods, in the same manner as the Epulones were at Rome.

They took care of the sacred corn, or the corn destined for the service of the temples, and the gods, viz. sacrifices, feasts, &c. they had even the intendance over sacrifices, and took care that they were duly performed. At Athens, there was a kind of college of twelve parasites; each people of Attica furnishing one, who was always chosen out of the best families.

Polybius adds, that parasite was also an honourable title among the ancient Gauls, and was given to their poets; but of late, it has been made a term of reproach, and used for a flatterer and mean dependant.

PARASITES, or *Parasitical Plants*, in botany, such plants as are produced out of the trunks or branches of other plants, from which they receive

their nourishment, and will not grow upon the ground; as the mistletoe, &c.

PARATHENAR, in anatomy, the name of two muscles of the foot; one of which, the parathenar major, is a pretty long muscle, forming a part of the outer edge of the sole of the foot.

It is fixed backward by a fleshy body to the outer part of the lower side of the os calcis, from the small posterior external tuberosity, all the way to the anterior tuberosity: there it joins the metatarsus, and at the basis of the fifth metatarsal bone separates from it again, and forms a tendon, which is inserted in the outside of the first phalanx of the little toe, near its basis, and near the insertion of the other parathenar: this last is called a parathenar minor; being a fleshy muscle fixed along the posterior half of the fifth bone of the metatarsus, and terminating under the head of that bone in a tendon, which is inserted in the lower part of the basis of the first phalanx of the little toe.

PARATHESIS, in grammar, the same with apposition. See APPPOSITION.

PARATITLES, *Paratitla*, in jurisprudence, short notes or summaries of the titles of the digest and code; which have been made by several lawyers, in order to compare and examine the connection of the several parts with one another. See the articles DIGEST and CODE.

PARBUNCLE, in a ship, the name of a rope almost like a pair of slings: it is seized both ends together, and then put double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it, to hoist it up by.

PARCÆ, in the heathen mythology, goddesses, who were supposed to preside over the accidents and events, and to determine the date or period, of human life.

PARCHMENT, in commerce, the skins of sheep or goats, prepared after such a manner as to render it proper to writing upon, covering books, &c.

PARAGORICS, in pharmacy, medicines that alluage pain, otherwise called anodynes. See the article ANODYNES.

PARELCON, in grammar, a figure by which a word or syllable is added to the end of another.

PARELIUM, or PARHELIUM. See the article PARHELIUM.

PARENCHYMA, in anatomy, a term introduced by Erasistratus, signifying all that substance which is contained in the interstices between the blood-vessels of the viscera, which he imagined to be extravasated and concremented blood. The moderns having discovered all the viscera to be vascular and glandulous, have rejected this term, together with the doctrine.

PARENCHYMA of Plants. Grew applies the term

term parenchyma to the pith or pulp, or that inner part of a fruit or plant through which the juice is supposed to be distributed. This, when viewed with a microscope, appears to resemble marrow, or rather a sponge, being a porous, flexible, dilatable substance. Its pores are innumerable and exceedingly small, receiving as much humour as is requisite to fill and extend them, which disposition of pores it is that is supposed to fit the plant for vegetation and growth.

**PARENT**, *Parents*, a term of relation applicable to those from whom we immediately receive our being. See **FATHER** and **MOTHER**.

**PARENTALIA**, in antiquity, funeral obsequies, or the last duties paid by children to their deceased parents.

It is also used for a sacrifice, or solemn service, offered annually to the manes of the dead.

**PARENTHESIS**, in grammar, certain intercalary words, inserted in a discourse, which interrupt the sense, or thread, but seem necessary for the better understanding of the subject.

The proper characteristic of a parenthesis is, that it may be either taken in or left out, the sense and the grammar remaining entire. In speaking, the parenthesis is to be pronounced in a different tone; and in writing, it is enclosed between ( ), called also a parenthesis, but commonly a bracket, or crotchet, to distinguish it from the rest of the discourse. The politest of our modern writers avoid all parentheses, as keeping the mind in suspense, embarrassing it, and rendering the discourse less clear, uniform, and agreeable.

The parenthesis is frequently confounded with the parembolē. See the article **PAREMBOLĒ**.

**PARGET**, in natural history, a name given to several kinds of gypsum, or plaster-stone. See **PLASTER**.

**PARGETING**, in building, is used for the plastering of walls, and sometimes for the plaster itself.

Pargeting is of various kinds, as, 1. white-lime, hair, and mortar, laid upon bare walls: 2. on bare laths, as in partitioning and ceiling: 3. rendering the insides of walls, or doubling partition walls: 4. rough-casting upon heart-laths: 5. plastering on brick-work, with a finishing mortar in imitation of stone-work.

**PARHELIUM**, or **PARHELION**, in physiology, a mock sun or meteor in form of a very bright light appearing on one side of the sun.

The parhelia are formed by the reflection of the sun's beams on a cloud properly posited. They usually accompany the coronæ, or luminous circles, and are placed in the same circumference and at the same height. Their colours resemble that of the rainbow, the red and yellow are on the side towards the sun, and the blue and violet on the other. There are coronæ sometimes seen without parhelia, and vice versa.

**Parhelia** are double, triple, &c. and in 1629, a parheliion of five suns was seen at Rome; and in 1666, another at Arles of six.

M. Mariotte accounts for parhelia from an infinity of little particles of ice floating in the air, that multiply the image of the sun by refraction or reflection; and by a geometrical calculus he has determined the precise figure of these little icicles, their situation in the air, and the size of the coronæ or circles which accompany the parhelia, and the colours wherewith they are painted. M. Huygens accounts for the formation of a parheliion in the same manner as for that of the halo. See the article **HALO**.

**PARIETALIA** *Ossa*, in anatomy, the second and third bones of the cranium; being called also ossa-bregmatis, and ossa-sincipitis.

**PARIETES**, in anatomy, a term used for the inclosures or membranes, that stop up or close the hollow parts of a body, especially those of the heart, thorax, &c.

**PARIETARIA**, **PELLITORY OF THE WALL**, in botany, a genus of plants, producing hermaphrodite and female, apetalous flowers; the calyx of each is a monophyllous perianthium: the stamina are four subulated filaments, topped with twin antheræ; there is no pericarpium, but the seed, which is single, and of an oval form, is contained in the cup. Pellitory flowers in May, and grows upon old walls and buildings in several parts of England.

This plant is very famous in the materia medica as cooling and abstergent. It is prescribed in stranguries, and in cases of gravel, or small stones in the kidneys, and is an ingredient in decoctions for clysters to be given in nephritic cases. Externally, it is much recommended in the erysipelas, and for the softening of hard tumours.

**PARIS**, herb true-love, in botany, a plant producing cruciform flowers: the fruit is a globose berry, containing four cells, which are filled with seeds arranged in a double series. This plant grows wild in moist shady woods in many parts of England.

**PARISH**, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church, and are under the particular charge of its minister.

A parish may contain several villages within its limits, though in general it is accounted to contain no more than one, except the contrary be made to appear: and an antient village, which time out of mind has had a church of its own, and chosen overseers, &c. may be a parish in reputation, so as to provide for its own poor only, and be excused from contributing to the poor of the parish in which it lies, 43 Eliz. c. 2.

In England there are nine thousand, nine hundred and thirteen parishes, of which three thousand,

land, eight hundred and forty-five are churches impropriate, and the rest are annexed to colleges, or church dignities. In many of these parishes, on account of their large extent, and the number of parishioners, there are several chapels of ease.

**PARISH-OFFICERS**, officers chosen annually to regulate and manage the concerns of the parish, for which see the articles **CHURCH-WARDENS**, and **OVERSEERS of the Poor**.

**PARK**, a large inclosure privileged, for wild beasts of chase, either by prescription or the king's grant. No person can now erect a park without his obtaining first a licence under the broad-seal; but there may be such in reputation, though erected without lawful warrant, and the owner may bring his action against persons that kill his deer therein. The pulling down walls, or pales, makes the offenders liable to the same penalty as for killing of deer.

**PARK**, is also used for a moveable inclosure, or fold, set up in the fields for sheep to feed and rest in during the night. This park is frequently removed by the shepherds to dung the ground one part after another.

**PARK**, also signifies a large net, placed on the brink of the sea, with only one entrance, which is next to the shore, and which is left dry by the ebb of the tide, so that the fish once got in, have no way left to escape.

**PARK of Artillery**. See the article **ARTILLERY-PARK**.

**PARK of Provisions**. See the article *Park of PROVISIONS*.

**PARKINSONIA**, in botany, a genus of plants, whose flower consists of five almost equal spreading petals; the stamina are ten declining filaments, terminated by oblong incumbent antheræ. The fruit is a long taper pod, with swelling joints, each articulation containing an oblong seed.

This plant grows naturally in the Spanish West-Indies, where it rises to the height of twenty feet or upwards: it bears long slender bunches of yellow flowers, which are pendent; they have a most agreeable scent, so as to perfume the air to a considerable distance; for which reason the inhabitants of the West-Indies plant them near their habitations. It is propagated from seeds; but in this climate requires a stove to preserve it.

**PARLEY**, a conference with an enemy. Hence to beat or sound a parley, is to give a signal for holding such a conference by beat of drum or sound of trumpet.

**PARLIAMENT**, is the grand assembly of the three states of this kingdom, summoned together, by the king's authority, to consult of matters relating to the public welfare, and particularly to enact and repeal laws. It consists of the king, the lords spiritual and temporal, and the commons, and is at

once the seat of the legislative authority, and the highest court of justice in Great-Britain. In the house of lords, criminal causes are tried on the impeachment of the commons; and this house has an original jurisdiction for the trial of peers upon indictments found by a grand jury; the lords likewise try such causes as come thither on appeals from the court of chancery, and all their decrees are as judgments. The house of commons examine the rights of elections, regulate disputes concerning them, may expel their own members, and commit them to prison; they are the grand inquest of the nation, and present public grievances or delinquents to the king and lords, in order to their being punished. In short, they are the representatives of all the commons in the kingdom, and in them their constituents have placed the highest confidence, by investing them with the power of making laws, and entrusting them with all their liberties and privileges. Originally, new parliaments were called every year; but by degrees their term grew longer. In the reign of king Charles II. they were held a long time, with great interruptions between: but both methods were found of such ill consequence, that, in the beginning of the reign of king William III. an act passed, by which the term of all parliaments was restrained to three sessions, or three years; this was hence called the triennial act: but since that time, from other views, the period of parliaments has been lengthened to seven years.

**PARLOUR**, a fair lower room, designed principally for the entertainment of company. See **APARTMENT**.

**PARNASSIA**, in botany, a genus of plants, whose flower has five roundish, emarginated, striated, concave, patent petals, with five cordated nectariums, and the same number of subulated filaments, terminated with depressed incumbent antheræ. The fruit is an oval four-cornered capsule, with one cell, containing a number of oblong seeds.

**PAROCHIAL**, something belonging to a parish. See **PARISH**, **CHURCH**, &c.

**PARODICAL** *Degrees of an Equation*, in algebra, are the several regular terms in quadratic, cubic, biquadratic equations, &c. the indexes of whose powers ascend or descend orderly in an arithmetical progress, as  $x^3 + x^2m + xr = s$ , is a cubical equation, where no term is wanting, but having all its parodic degrees, the indexes of the terms regularly descending thus, 3, 2, 1, 0.

**PARODY**, *παρωδια*, a popular maxim, adage, or proverb.

Parody is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule to another; or in turning a serious work into a burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences.

It comes near to what some of our late writers call travesty; and was first set on foot by the Greeks, from whom we borrow the name.

**PAROL**, or **PAROLE**, in law, is used for a plea in court: sometimes this word is joined with the term lease; thus lease-parol denotes a lease by word of mouth, in order to distinguish it from a lease in writing.

**PARONYCHIA**, whitlow, in medicine, an inflammatory and exceeding painful disorder, which invests all the joints, and particularly the ends of the fingers; being generally much swelled with a beating or throbbing, and intense heat. There is sometimes little or no tumour observed, when the disorder lies deep at, or in the bone; and sometimes again the tumour, pain, and inflammation, are extended from the finger, up to the elbow, or even to the shoulder, from the communication of the fingers with those parts by the flexor-muscles.

For the cure of a paronychia, Garengot proposes incision before any trial has been made with other remedies; but Heister, agreeably to the advice of Hippocrates, is of opinion, that the disorder may be frequently dispersed and removed by the use of deluent, discutient, and cooling remedies, without any incision. The most approved method for removing an inflammation and obstruction in this manner, is to let the patient hold his finger, for several hours, in spirit of wine, highly rectified, and in which has been infused camphor or theriaca. See the articles **DISPERSION**, **DILUENT**, **DISCUTIENT**, &c.

But when there is already a suppuration actually formed, either before or under the use of these means, then an incision is the only remedy. In the first species of this disorder, the surgeon, as soon as he perceives the matter to point, or form a little protuberance, ought to hold and press it between the finger and thumb of his left hand, while he makes a longitudinal incision therein, with his right, by which means the matter being discharged, the finger will then heal almost of itself. In the second species of the paronychia, an incision is to be made according to the preceding directions; only then more care is to be taken, that the knife penetrate to the bone: the incision being made, the blood should be suffered to flow out a little while, either of itself, or else it should be pressed out; then the wound is to be dressed with dry lint, and diachylon plaster, with a compress dipped in warm spirit of wine, and retained on by a proper bandage: the wound is next to be treated like those in which the bones are affected, viz. with essence of myrrh, amber, balsam of Peru, &c.

**PAROTIDES**, in anatomy, two very remarkable glands, situated one on each side, between the ear and the angle of the lower jaw, and often extending themselves over a great part of the masseter. From each of these glands there runs a very large

duct, about three fingers-breadth long, and of the thickness of a wheat-straw, having a great number of roots: this duct, from Steno, the discoverer, is by some called ductus salivalus Stenonius, by others ductus salivalus superior. It passes over the masseter-muscle, through the middle of the cheek, and there perforates the buccinator-muscle, and the membrane of the mouth, near the second or third of the dentes molares, and at this perforation it discharges a very large quantity of its proper fluid into the mouth. The parotides are among those glands that serve for the secretion of the saliva. See the articles **GLAND** and **SALIVA**.

**PAROTIDES** is also the name of certain tumours or inflammations arising behind the ears, or the parotid glands.

**PAROXISM**, in medicine, the severe fit of a disease, under which it grows higher, or exasperates, as of the gout, &c.

It is also used for the access or return of a disease, as an ague, &c.

**PARRELS**, in a ship, are frames made of trucks, ribs, and ropes, which having both their ends fastened to the yards, are so contrived, as to go round about the mast; that the yards, by their means, may go up and down upon the masts; these also, with the breast-ropes, fasten the yards to the masts.

**PARRICIDE**, *Parricida*, or *Patricida*, strictly signifies the murder or murderer of a father, as matricide does of a mother; yet this word is ordinarily taken in both senses, and is also extended to the murder of any near relation, as husband, wife, brother, sister, child, grand-child, uncle, &c. and even to that of great or sacred persons, though no way allied in blood, as a king, &c.

**PARROQUET**, in ornithology, a subdivision of parrots. See the next article.

**PARROT**, *Psittacus*, a genus of birds, of the order of the accipitres, the characters of which are these; the beak is of a hooked or uncinated figure; and the toes are four on each foot, two forwards and two backwards.

**PARRYING**, in fencing, the action of warding off the blows aimed at one by another. See the article **FENCING**.

**PARSLEY**, *Apium*, in botany, a genus of umbelliferous plants; the flower is composed of five pale petals, with five stamina; these are succeeded by seeds that are joined by pairs, and are slender, furrowed, grey, and roundish at the back. Parsley is cultivated in gardens for culinary purposes, it being more used in the kitchen than any other herb whatsoever; it will tolerably endure cold, but is apt to be destroyed in very severe winters, especially where the land is moist; it is commonly sown in the spring, and sends forth a stalk the year after, which flowers in June or July, and the seeds ripen in August.

The

The common parsley is, by some skilful people, cultivated in fields for the use of sheep, it being a sovereign remedy to preserve them from the rot, provided they are fed twice a week, for two or three hours each time, with this herb : but hares and rabbits are so fond of it, that they will come from a great distance to feed on it ; so that whoever has a mind to have plenty of hares in their fields, by cultivating parsley, will draw all the hares off the country to them.

The leaves of parsley are cooling, and good for cleansing the viscera ; they also absterge much slime and viscid adhesions from the stomach and bowels, cleanse all the passages, keep the juices fluid, and greatly assist their discharge by urine. The root is one of the five opening roots ; it is attenuant, aperient, detergent, and diuretic ; it is good in decoctions, diet-drinks, and medicinal ales, for cleansing the blood (as it is commonly called) and draining off ill humours by urine. The seed is one of the four hot seeds, and is said to be good in the gravel and dropsy.

*Macedonian PARSLEY.* See the article BUBON.

PARSNIP, *Pastinaca*, in botany, a genus of umbelliferous plants, the universal flower of which is uniform, and the particular ones are each composed of five lanceolated incurved petals, with five hairy stamina ; there is no pericarpium, but the fruit, which is plane, elliptical, and compressed, is composed of two flattish marinated seeds.

The garden parsnip is propagated by sowing its seeds in February or March, on a rich ground of a good depth, and afterwards hoed out as is practised with turneps, and in autumn the roots are to be dug up, and preserved for winter and spring use : the year after sowing, the flower-stalk arises to the height of three or four feet, and is upright, firm, furrowed, hollow, and branched ; the leaves are large and composed of other leaves, that are villous, dentated on their edges, and winged ; they are of a brownish green, and placed by pairs along the rib, which is terminated by a single leaf ; the flowers are yellow, and come out in July or August, and the seeds are ripe about the beginning of September.

The roots of this plant are of great use as food, for which they are chiefly cultivated ; they are more nourishing than carrots, though some people have a natural aversion to their use. The roots and seeds of wild parsnip are sometimes used in medicine, and are recommended as a remedy against agues, and are reckoned good in flatulencies and cholics.

PARSON, the rector or incumbent of a parish-church. See the articles CHURCH and CLERGY.

PARSON IMPARSONEE, signifies one that is in possession of a church, whether it be presentative or of inappropriate, and with whom the church is then full.

PARSONAGE, a rectory or parish-church, endowed with a house, glebe, lands, tythes, &c. for the maintenance of a minister, with cure of souls within such parish. There may, notwithstanding, be a parsonage without either glebe or tythes, but only annual payments instead thereof.

PART, *Part*, a portion of some whole, considered as divided or divisible.

*Consent of PARTS*, in medicine. See the article CONSENT.

PART, in geography and astronomy, is applied to the division of lines and circles, &c.

*Aliquot PART*, and *Aliquant PART*, in arithmetic. See the articles ALIQUOT and ALIQUANT.

*Proportional PART*, is a part or number agreeable or analogous to some other part or number ; or a medium to find some number or part unknown, by proportion and equality of reason.

*Similar PARTS*, are those which are to one another, as their wholes are to one another.

PART, in music, denotes a piece of the score, or partition, written by itself, for the convenience of the musician ; or, it is one or more of the successions of sounds, which make the harmony, written apart. Or, the parts are the sounds made by several persons, singing or playing in concert.

Music in parts was unknown to the ancients ; they had but one part : all their harmony consisted in the succession of notes, none in the consonance.

There are four principal parts, the treble, base, tenor, and counter-tenor. Some compare the four parts in music to the four elements ; the base, they say, represents the earth ; the tenor, the water ; counter-tenor, air ; and treble, fire.

*PARTS of Speech*, in grammar, are all the sorts of words which enter the composition of discourse. See SPEECH.

The grammarians generally admit of eight parts of speech, viz. noun, pronoun, verb, participle, adverb, preposition, interjection, and conjunction. See NOUN, PRONOUN, &c.

PARTERRE, in gardening, a level division of ground, which, for the most part, faces the south and best front of the house ; and is generally furnished with greens, flowers, &c.

There are several sorts of parterres, as plain grass with borders, and parterres of embroidery, &c.

Plain parterres are more beautiful in England than in any other country, by reason of the excellency of our turf, and that decency and unaffected simplicity that it affords to the eye of the spectator. Other parterres are cut into shell and scroll work, with sand-alleys between them ; which sort of parterres are esteemed finest in France.

As to the general proportions of parterres, an oblong, or long-square, is esteemed the best : therefore, a parterre should not be less than twice as long as it is broad ; twice and a half is accounted a very good

good proportion; and it is very rare that three times is exceeded. As to the breadth of a parterre, it is to take its dimensions from the breadth of the front of the house; if the front of the house is one hundred feet long, the breadth of the parterre should be one hundred and fifty feet; and if the front of the house be two hundred feet, the parterre should be fifty feet broader: but where the front exceeds the breadth of this parterre, it will be a good proportion to make the parterre of the same dimensions with the front.

There should be a terrace-walk on each side of the parterre, for an elevation proper for view; and therefore, there should never be the flat of a parterre between terrace-walk and terrace-walk, above three hundred feet; nor can it be well made less than one hundred and forty. As to the adorning and furnishing these parterres, whether it be plain or with embroidery, that depends much upon the form of them, and therefore must be left to the judgment and fancy of the designer.

**PARTHENIUM**, American-feverfew, in botany, a genus of plants, the compound flower of which is convex; there are several corollulæ in the disc, which are monopetalous, tubulose, ligulated, erect, quinquid at the mouth, and of the length of the cup; the female flowers are also monopetalous, but they are tubulated, ligulated, oblique, obtuse, roundish, and of the length of the hermaphrodite ones; they are five in number, and are placed in the verge or radius: there is no other fruit but the cup, which remains upon the plant unaltered: the seeds in the hermaphrodite flowers are abortive; and in the female it remains in the cup, and is single, of a turbinato-cordated form, compressed, and naked.

The leaves and flowers of this plant are recommended in frigid and flatulent affections of the uterus, in obstructions of the menses, in venereal weaknesses, and in the dropsy. They are also of great use in putrid fevers, the stone in the kidneys, vertigo, and arthritis.

**PARTI**, **PARTIE**, **PARTY**, or **PARTED**, in heraldry, is applied to a shield or escutcheon, denoting it divided or marked out into partitions. See the articles **SHIELD**, &c.

**PARTI per Pale**, is when the shield is divided perpendicularly into two halves, by a cut in the middle from top to bottom.

**PARTI per Fess**, is when the cut is across the middle, from side to side.

**PARTI per Bend Dexter**, is when the cut comes from the upper corner of the shield, on the right hand, and descends athwart to the opposite lower corner.

**PARTI per Bend Sinister**, is when the cut, coming from the upper left corner, descends across to the opposite lower one.

From these four partitions have proceeded an infinite number of others, of various and extravagant forms.

**PARTICIPATION**, that which gives a part or share in any thing, either by right or grace.

**PARTICIPLE**, *Participium*, in grammar, an adjective formed of a verb, so called because it participates partly of the properties of a noun, and partly of those of a verb; being variable through genders and cases, like the former; and regarding time, action, passion, &c. in manner of the latter. See **NOUN** and **VERB**.

In our language, the participles and gerunds are not at all distinguishable. See **GERUND**.

**PARTICLE**, in physiology, the minute part of a body, an assemblage of which constitute all natural bodies. See **ATOM** and **MATTER**.

It is the various arrangement and texture of these particles, with the difference of cohesion, &c. that constitute the various kinds of bodies. The smallest particles cohere with the strongest attraction, and compose bigger particles of weaker cohesion, and many of these cohering compose bigger particles, whose vigour is still weaker; and hereupon the operations in chemistry, and the colours of natural bodies depend, and which, by cohering, compose bodies of sensible bulk.

The cohesion of the particles of matter, the Epicureans imagined, was affected by means of hooked atoms; the Aristotelians, by rest; but Sir Isaac Newton shews, that it is done by means of a certain power, whereby the particles mutually attract and tend towards each other. By this attraction of the particles, he shews, that most of the phenomena of the lesser bodies are affected, as those of the heavenly bodies are, by the attraction of gravity. See **ATTRACTION** and **GRAVITATION**.

**PARTICLE**, in grammar, a denomination for all those small words that tie or unite others together, or that express the modes or manners of words, usually included, by grammarians, under these four parts of speech, viz. adverbs, prepositions, interjections, and conjunctions. See the articles **PARTS of Speech**, **ADVERB**, &c.

**PARTIES**, in law, signify the persons that are named in a deed or fine, viz. those that made the deed, or levied the fine, and also those to whom the same was made or levied.

**PARTING**, or **DEPARTING**, a method of separating gold and silver, by means of aqua-fortis; for the operation of which, see **ASSAYING** and **QUARTATION**.

**PARTITION**, in law, signifies a division of lands, &c. descended by common law or custom among coheirs or parceners, being two at least. Partition may also be made by joint tenants, and tenants in common by assent, deed, or writ. See **CO-PARCENERS**.

**PARTNER**, and **PARTNERSHIP**. See the article **FELLOWSHIP**.

**PARTRIDGE**, in ornithology, is a species of tetrao, with a naked scarlet mark behind the eyes.

The common partridge is too well known to need a farther description: it is common in fields, and called by authors perdix. But besides the common kind, there is another somewhat larger species, called the red-legged partridge, with a grey tail, variegated in the upper part with brown.

**PARTURITION**, the same with delivery. See **DELIVERY**.

**PARULIDES**, in surgery, tumours and inflammations of the gums, commonly called gum-boils.

They are to be treated with discutients, like other inflammatory tumours. Sage, camomile, and elder-flowers, boiled in milk or water, make a gargarism to be held in the mouth warm; and the remaining herbs may be sewed up in a bag, and applied hot to the cheeks. See the article **DISPERSION**.

But if the disorder cannot be thus dispersed, emollient applications of mallows, &c. are good; and to forward the maturation externally, a half-roasted fig may be applied: and when the softness of the tumour shews that the matter is suppurated, it ought immediately to be opened by the lancet, to prevent the matters lodging there, and eroding the bone, and producing a fistula or caries. After it is opened, the matter should be gently pressed out with the fingers, and the mouth frequently washed with red wine, mixed with a decoction of vulnerary herbs, till it is well.

When the ulcer has penetrated deep, it will be necessary to inject the same liquors with a syringe, and compress the part by a proper external bandage, to make the bottom heal first; and when it is already become fistulous, and has callous edges, it may then often be cured by injecting tincture of myrrh, and elixir proprietatis, continuing this for some time. If all these prove ineffectual, the fistula must be laid open by incision, and the caries removed by medicines, caustics, or the actual cautery. If this proceeds, as sometimes it does, from a carious tooth, this is first of all to be extracted, otherwise the tumour will degenerate into a fistula: and it is always best to be early in making the incision.

**PASPALUM**, in botany, a genus of plants, whose flower is a bivalvular glume, with three capillary filaments, topped with ovate antheræ: the fruit is a persistent glume, in which is placed one roundish compressed seed.

**PASQUE**. See **PULSATILLA**.

**PASQUIN**, a mutilated statue at Rome, in the corner of the palace of the Ursini.

It takes its name from a cobbler of that city, called Pasquin, famous for his sneers and gibes, and who diverted himself with passing his jokes on all the people who went through the street. After his death, as they were digging up the pavement before his shop, they found in the earth the statue of an ancient gladiator, well cut, but maimed, and half

spoiled; this they set up in the place where it was found, and by common consent named it Pasquin. Since that time, all satires are attributed to that figure, and are either put into its mouth or pasted upon it, as if they were wrote by Pasquin redivivus; and these are addressed by Pasquin to Marforio, another statue at Rome. When Marforio is attacked, Pasquin comes to his assistance; and when Pasquin is attacked, Marforio assists him in his turn.

**PASQUINADE**, a satirical libel fastened to the statue of Pasquin: these are commonly short, merry, and pointed; and hence the term has been applied to all other lampoons of the same cast.

The difference between a pasquinade and a satire is, that the end of the latter is to correct and reform, while that of the former is only to ridicule and expose.

**PASS**, a straight, difficult, and narrow passage, which shuts up the entrance into a country.

The first care of the general of an army is to seize the passes of the country into which he would carry the war, to fortify them, and take care that they are well guarded.

**PASS of Arms**, in chivalry, a bridge, road, &c. which the ancient knights undertook to defend.

**PASS**, or **PASSADE**, in fencing, an advance or leap forward upon the enemy.

**PASSADE**, in the manege, is a turn or course of a horse backwards or forwards, on the same spot of ground.

**PASSAGE**, in the manege, is a horse's walking or trotting in such a manner that he raises the outward hind-leg, and the inward fore leg together; and setting these two on the ground, raises the other two alternately, never gaining above a foot of ground at a time.

**PASSAGE**, or **PASSO**, in music, a part of an air or tune, consisting of several short notes, as quavers, semi-quavers, &c. lasting one, two, or, at most, three measures, in the beginning of a piece, which is to be afterwards imitated in the other notes of the piece, not with the same chords or notes, but only by observing the same motion, number, and figure, as in the notes of the first passage. This is called by the Italians, *contrapunto d'un sol passo*.

**Birds of PASSAGE**, a name given to those birds which, at certain stated seasons of the year, remove from certain countries, and at other stated times return to them again, as our quails, woodcocks, storks, nightingales, swallows, and many other species.

**Right of PASSAGE**, in commerce, is an imposition or duty exacted by some princes, either by land or sea, in certain close and narrow places in their territories, on all vessels and carriages, and even sometimes on persons or passengers, coming in or going out of ports, &c.

The most celebrated passage of this kind in Europe

rope is the Sound, the dues for passing which strait belong to the king of Denmark, and are paid at Elsenore or Cronenburg.

**PASSANT**, in heraldry, a term applied to a lion or other animal, in a shield, appearing to walk leisurely. For most beasts, except lions, the term trippant is frequently used instead of passant.

**PASSERES**, the name of a class of birds with a conic and much attenuated beak. See the article **ORNITHOLOGY**.

**PASSERINA**, sparrow-wort, in botany, a genus of plants, whose flower is monopetalous, the tube whereof is slender, narrow, and swelling in the middle; the limb is patent, and divided into four segments: the stamina are eight setaceous filaments, topped with erect antheræ; and the fruit is an oval, coriaceous, unilocular capsule, containing a single ovate seed, pointed at both ends.

**PASSIFLORA**, the passion-flower, in botany, a genus of plants, whose flower-cup is formed of five plane coloured leaves; the corolla consists of five semi-lanceolated obtuse petals; the nectarium hath a triple crown, the exterior of which is longer, and fastened to the inside of the petal, but is larger and compressed above: the stamina are five subulate filaments, fastened at their base to the column of the style, annexed to the germen, spreading out, and terminated by oblong, obtuse, incumbent antheræ: the fruit is an ovate, fleshy, unilocular berry, supported on a pedicle, and contains a number of ovate seeds, fastened longitudinally to the bark of the pericarpium.

The common passion-flower hath long slender stalks, which run a great length, and require support; they are covered with a purplish bark, and are furnished at each joint with a digitated leaf, composed of five smooth entire lobes, connected with the stalk by pedicles, about two inches long, having two small leaves embracing the stalks at their base; and from the same point comes out a long tendril, which twists round the neighbouring support; the flowers come out at the same joints as the leaves, supported on foot-stalks almost three inches long; these flowers have a faint smell, and continue but one day; they come out in July, and there is a diurnal succession till the frost in autumn puts a stop to them.

This plant may be propagated either from seeds, layers, or cuttings; they require a good aspected wall; where they may have height for their shoots to extend, which should be properly trained against it; and in the spring the plants must be pruned, when all the small weak shoots should be cut off, and the strong ones shortened to about four or five feet long, which will cause them to put out strong shoots for flowering the following summer.

**PASSION-FLOWER**, *Passiflora*, in botany. See the article **PASSIFLORA**.

**PASSIONS**, in moral philosophy, are certain motions of the soul, which makes it pursue what appears to be good, and avoid whatever threatens evil. See the articles **GOOD** and **EVIL**.

**PASSIONS**, in medicine, make one of the non-naturals, and produce very sensible effects. Joy, anger, and fear, are the principal. In the two first, the spirits are hurried with too great vivacity; whereas, in fear or dread, they are as it were curbed and concentrated: whence we may conclude, that they have a very bad effect upon health; and therefore, it will be best to keep them within bounds as much as possible, and to preserve an inward serenity, calmness, and tranquility.

Continual sorrow and anguish of mind, render the fluids thick, and generate viscid and acid crudities in the stomach, and at length render the body unapt for a due circulation; whence proceed obstructions of the viscera, and many chronical disorders.

Anger constricts the bilious vessels in particular, and causes too great an evacuation of the bile, produces strictures in the stomach and duodenum; whence the bilious humours are amassed and corrupted; laying a foundation for vomiting, bilious fevers, and cardialgia.

**PASSIONS**, in painting, are the external expressions of the different dispositions and affections of the mind; but particularly their different effects upon the several features of the face: for though the arms, and indeed every part of the body, serve likewise, by their quick, languid, and variously diversified motions, to express the passions of the soul; yet, in painting, their difference is most conspicuous in the face.

**PASSIONS**, in poetry, are of singular use in distinguishing the characters of the actors. See the article **CHARACTER**.

**PASSION**, or *Cross of the PASSION*, in heraldry, is so called, because resembling the shape of that on which our Saviour is thought to have suffered; that is, not crossed in the middle, but a little below the top, with arms short in proportion to the length of the shaft.

**PASSION-WEEK**, the week immediately preceding the festival of Easter: so called, because in that week our Saviour's passion and death happened.

**PASSIVE**, in general, denotes something that suffers the action of another, called an agent, or active power.

**PASSOVER**, a solemn festival of the Jews, celebrated on the fourteenth day of the month next after the vernal equinox, and instituted in commemoration of their coming out of Egypt; because on the night before their departure, the destroying angel, who put to death the first-born of the Egyptians, passed over the houses of the Hebrews, which were sprinkled with the blood of a lamb. The whole

whole transaction is related in the twelfth chapter of Exodus.

**PASS-PAROLE**, a command given at the head of an army, and thence communicated to the rear by passing it from mouth to mouth.

**PASS-PAR-TOUT**, a master-key; or a key that opens several locks belonging to the same house or apartment.

**PASS-PORT**, or **PASS**, a licence or writing obtained from a prince or governor, granting liberty and safe conduct to pass through his territories without molestation.

**PASTBOARD**, a kind of thick paper formed of several sheets of paper pasted together.

**PASTE**, a composition of water and flower, boiled to a consistence; used by various artificers, as sadlers, upholders, bookbinders, &c.

**PASTEL**, a name by which some call isatis, or woad. See the article **ISATIS**.

**PASTERN** of a *Horse*, in the manege, is the distance between the joint next the foot, and the coronet of the hoof. This part should be short, especially in middle-sized horses, because long pasterns are weak, and cannot so well endure travelling.

**PASTERN-JOINT**, the joint next a horse's foot.

**PASTIL**, or **PASTEL**, among painters, a kind of paste made of different colours, ground up with gum-water, in order to make crayons. See the article **CRAYON**.

**PASTIL**, in pharmacy, is a dry composition of sweet-smelling resins, aromatic woods, &c. sometimes burnt to clear and scent the air of a chamber.

**PASTINICA**, the parsnep, in botany. See the article **PARSNEP**.

**PASTOR**, properly signifies a shepherd, but is now generally used for a parson or minister that hath cure of souls.

**PASTORAL**, in general, something that relates to shepherds; hence we say, pastoral life, manners, poetry, &c.

The original of poetry is ascribed to that age which succeeded the creation of the world: and as the keeping of flocks seems to have been the first employment of mankind, the most antient sort of poetry was, probably, pastoral. It is natural to imagine, that the leisure of those antient shepherds admitting and inviting some diversion, none was so proper to that solitary and sedentary life as singing; and that in their songs they took occasion to celebrate their own felicity. From hence a poem was invented, and afterwards improved to a perfect image of that happy time; which, by giving us an esteem for the virtues of a former age, might recommend them to the present. And since the life of shepherds was attended with more tranquillity than any other rural employments, the poets chuse to introduce their persons, from whom it received the name, of pastoral.

**PASTORAL COLUMN**. See **COLUMN**.

**PASTORAL STAFF**, the same with crozier. See the article **CROZIER**.

**PASTRY**, that branch of cookery, which is chiefly taken up in making pies, pasties, cakes, &c.

**PASTURE**, or **PASTURE LAND**, that reserved for feeding cattle.

Pasture-land is of such advantage to husbandry that many prefer it even to corn-land, because of the small hazard and labour that attends it, and as it lays the foundation for most of the profit that is expected from the arable land, because of the manure the cattle afford which are fed upon it. Where dung is not to be bought, as is often the case in places distant from large towns, the farmer is forced to proportion his arable to his pasture land, in such manner, that the cattle fed on the latter may be sufficient for a supply of dung, so necessary for producing the fruits of the former.

Pasture-lands are of three kinds: 1. The uplands: these lie so high as not to be overflowed by rivers, or land-floods. 2. Those low lands which lie near rivers and fens. And, 3. Those that lie near the sea. See the articles **UPLAND**, **MARSH-LAND**, &c.

Pasture-land requires the refreshment of dung, as well as the arable or corn-land; but there is to be a difference made in the laying it on and spreading it. A harrow performs the office of spreading the dung on ploughed lands; but the best contrivance for pastures is, to lay the dung in small heaps, and draw over it a gate stuck full of bushes. All dung that is laid on pasture-land, must be laid on in winter, that the rain may wash its fatness into the ground before the sun scorches it, or evaporates its goodness. Fine mould mixed with the dung, and spread with it over the land, is very good for pastures; for it is washed down to the very roots of the grass, and gives them a new and fine soil in those places where it is most wanted.

The best manure for pasture-land is the rotten bottoms of old hay-stacks; for these moulder away into a very rich soil, and are always full of vast quantities of seed, fallen at times from the hay, which all grow when spread on the ground: and thus new nourishment, and a new set of plants are given at once to the exhausted ground. But as particularly useful as this is for pasture-ground, it is as improper for corn-land, and should by no means ever be suffered to mix with the manure for those grounds; as it will then raise grass and other plants, which though of use in the pasture are weeds among the corn.

*Admeasurement* of **PASTURE**. See the article **ADMEASUREMENT**.

**PASTURE** of *Plants*, a term used by Tull, for the nourishment they draw from the earth. See the articles **PLANT** and **VEGETATION**.

**PASTY**, in cookery, a preparation of venison, veal,

veal, lamb, or other meat ; which being well boned, beaten to a pulp, and highly seasoned, is inclosed in a proper paste, and baked in an oven.

**PATAGONULA**, in botany, a genus of plants, whose flower-cup is a small, persistent, quinque-dentated perianthium ; the corolla is monopetalous and wheel-shaped, with scarce any tube ; the limb is plane, and divided into five ovate acute segments. The fruit is an ovate acuminate capsule, containing a number of roundish seeds.

**PATAVINITY**, *Patavinitas*, among critics, denotes a peculiarity of Livy's diction, derived from Patavium, or Padua, the place of his nativity ; but wherein this pavinity consists, they are by no means agreed.

**PATE'E**, or **PATTEE**, in heraldry, a cross small in the center, and widening to the extremes, which are very broad.

**PATELLA**, in anatomy, a bone which covers the fore-part of the joint of the knee, called also rotula, and popularly the knee-pan. The patella is convex on the outside, and on the inside unequal, having an eminence and two depressions. Its substance is spongy, and consequently it is brittle : it is connected by tendons and ligaments to the tibia and the os femoris, which is the ligament by which it is connected to the thigh, and has a motion of ascent and descent in the flexion of the tibia. In infants and children it is cartilaginous.

**PATENT**, in general, denotes something that stands open or expanded : thus a leaf is said to be patent when it stands almost at right angles with the stalk.

**PATENT**, or **LETTERS PATENT**. See the article **LETTER**.

**PATENTEE**, a person to whom the king has granted his letters-patent.

**PATERPATRATUS**, in Roman antiquity, the principal person among the *feciales* or college of heralds. See the article **FECEALES**.

**PATER-NOSTER**, the Lord's prayer, so called from the two first words in Latin. It is also sometimes used for a chaplet or string of beads. And, in architecture, the same term is used for a sort of ornament cut in the form of beads, either oval or round, used on astragals, baguettes, &c.

**PATH**, in general, denotes the course or tract marked out to run over, by a body in motion. See **MOTION**.

**PATH of the Vertex**, a term frequently used by Mr. Flamstead, in his doctrine of the sphere, for a circle described by any point of the earth's surface, as the earth turns round its axis.

The semi-diameter of this path is always equal to the sine of the complement of the latitude of the point that describes it.

**PATHETIC**, whatever relates to the passions, or that is proper to excite or awake them.

**PATHETIC Nerves**, in anatomy, a pair of very

small nerves which arise in the brain, and run to the trochlear muscle of the eye. These nerves have obtained the name pathetic, from their serving to move the eyes in the various passions.

**PATHOGNOMONIC**, *παθωγνωμονικος*, among physicians, an appellation for a symptom, or concurrence of symptoms, that are inseparable from a distemper, and are found in that only, and no other.

**PATHOLOGY**, that part of medicine, which explains the nature of diseases, their causes and symptoms.

**PATHOS**, *παθος*, a Greek term, literally signifying passion, is sometimes used for the energy of a discourse, or its power to move the passions.

**PATIENT**, among physicians, a person under the direction of a physician or surgeon, in order to be cured of some disease.

**PATANCE**, in heraldry, is a cross flory 'at the ends ; from which it differs only in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the pattee-form.

**PATRICIAN**, among the antient Romans, a title given to the descendants of the hundred, or, according to others, of the two hundred first senators chosen by Romulus, and by him called *patres*, fathers.

**PATRIPASSIANS**, *Patripassiani*, in church-history, a Christian sect, who appeared about the latter end of the 11d century ; so called from their ascribing the passion to the father : for they asserted the unity of God in such a manner as to destroy all distinction of persons, and to make the Father and Son precisely the same ; in which they were followed by the Sabellians, and others. The author and head of the patripassians was Praxeas, a philosopher of Phrygia in Asia.

**PATROL**, in war, a round or march made by the guards, or watch, in the night-time, to observe what passes in the streets, and to secure the peace and tranquility of a city or camp. The patrol generally consists of a body of five or six men, detached from a body on guard, and commanded by a sergeant.

**PATRON**, among the Romans, was an appellation given to a master who had freed his slave.

Patron was also a name which the people of Rome gave to some great man, under whose protection they usually put themselves.

**PATRON**, in the canon and common law, is a person, who having the advowson of a parsonage, vicarage, or the like spiritual promotion, belonging to his manor, hath, on that account, the gift and disposition of the benefice, and may present to it whenever it becomes vacant.

**PATRONAGE**, the right of disposing of a church or benefice, and enjoying several other privileges, such as having the honourable rights of the church, being interred in the chancel, &c.

**PATRONYMIC**, among grammarians, is applied

plied to such names of men or women as are derived from those of parents or ancestors.

**PAVEMENT**, a layer of stone, or other matter, serving to cover and strengthen the ground of divers places for the more commodious walking on.

*Mosaic PAVEMENT.* See **MOSAIC-WORK**.

**PAVETTA**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is long, narrow, and cylindrical, with a patent border cut into four segments; the filaments are four, and very short; these are topped with linear, spreading antheræ. The fruit is a roundish unilocular berry, containing a roundish cartilaginous seed.

**PAVIA**, the scarlet horse-chestnut, in botany, a plant which grows to the height of eight or ten feet, having a thick woody stalk, from which proceeds several spreading branches; these are furnished with digitated leaves, composed of five or six spear-shaped lobes, which join at the footstalk; they are of a light green, the surface rough and ferrated on their edges; they have long footstalks, and stand opposite by pairs: the flowers come out in July, in loose spikes at the ends of the branches, standing upon long naked footstalks, which sustain five or six flowers, which are tubulous at bottom, but spread open at top, where the petals are irregular in size and length, having the appearance of a labiated flower; they are of a bright red colour, and have seven or eight stamina the length of the petals: when the flowers fade, the germen swells to a pear-shaped fruit, with a thick russet cover, having three cells, one of which, and sometimes two, are pregnant with globular seeds.

This plant grows naturally in Carolina, and is propagated by sowing its seeds, or by budding, or grafting it upon the common horse-chestnut.

**PAVICULA**, among the Romans, a rammer or instrument for beating down or levelling a spot of ground, consisting of a block of wood, a foot long and half a foot thick, with a long handle.

**PAVILION**, in architecture, signifies a kind of turret or building, usually insulated, and contained under a single roof; sometimes square, and sometimes in form of a dome: thus called from the resemblance of its roof to a tent.

Pavilions are sometimes also projecting pieces, in the front of a building, marking the middle thereof; sometimes the pavilion flanks a corner, in which case it is called an angular pavilion. The Louvre is flanked with four pavilions: the pavilions are usually higher than the rest of the building. There are pavilions built in gardens, commonly called summer-houses, pleasure-houses, &c. Some castles or forts consist only of a single pavilion.

**PAVILION**, in military affairs, signifies a tent raised on posts, to lodge under in summer time. See the article **TENT**.

**PAVILION**, in heraldry, denotes a covering in form of a tent, which invests or wraps up the ar-

mories of divers kings and sovereigns, depending only on God and their sword.

**PAVILIONS**, among jewellers, the undersides and corners of the brilliants, lying between the girdle and the collet.

**PAULIONISTS**, in church-history, Christian heretics of the third century, disciples of Paul Samosatensis, bishop of Antioch, who denied Christ's divinity, maintaining that when we call him the Son of God, we do not thereby mean that he is really and truly God; but only that he was so perfect a man, and so superior in virtue to all others, that he has this name given him by way of eminence. The paulionists continued to the Vth century, notwithstanding the prohibition of the emperor Constantine the great, who forbid them and other heretics to hold public assemblies.

**PAULICIANS**, Christian heretics of the VIIth century, disciples of one Constantine, a native of Armenia, and a favourer of the errors of Manes; who, as the name Manichees was become odious to all nations, gave those of his sect the title of Paulicians, on pretence that they followed only the doctrine of St. Paul. One of their most detestable maxims was, not to give alms to the poor, that they might not contribute to the support of creatures, who were the works of the bad god. See the article **MANICHEES**.

**PAULLINIA**, in botany, a genus of plants, the corolla of which consists of four oval oblong petals, double the size of the cup, with two nectaria inserted into the unguis of the petals; the stamina are eight short filaments, topped with small antheræ; the fruit is a large three cornered capsule, with three cells, each containing an ovate seed.

This genus includes the serjana, and cururu of Plumier.

**PAUNCH**, **PANTCH**, or **PANCH**, on board a ship, are broad clouts, woven of thrums and sinners together, to save things from galling and fretting; therefore they are made fast to the main and fore-yards for that purpose.

**PAVO**, in astronomy, a southern constellation, called the peacock.

**PAUPER**, in law. See the article **FORMA PAUPERIS**.

**PAUSE**, a stop or cessation of speaking, singing, playing, or the like. The use of pointing in grammar, is to make proper pauses in certain places. There is a pause in the middle of each verse; in an hemistich it is called a rest or repose.

**PAUSE**, in music, a character of silence or rest, called also by some a mute figure; because it shews that some part or person is to be silent while the rest continue the song.

**PAW**, **PATTE**, in heraldry, the fore foot of a beast, cut off short. If the leg be cut off, it is called gambe. Lions-paws are much used in armory.

## PEA

PEA, *Pisum*, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is broad heart-shaped, reflexed, emarginated, and ending in a point; the alæ are roundish, connivent, and shorter than the vexillum; the carina is compressed, femilunulated, and shorter than the alæ; the fruit is a large, long, unilocular, and bivalve pod, containing several globose seeds. The stalks of the pea plant are long, hollow, and of a sea green colour; the leaves are oblong, and of the same colour; and some are so placed that the stalks seem to run through them, while others grow by pairs on the ribs that are terminated by tendrils, which lay hold of every thing they meet with. There are several sorts of peas, which are distinguished by different names; as the golden-hot-spur, the Charlton-pea, the reading-master's and Essex hot-spurs, the dwarf-pea, the sugar-pea, the Spanish-morotto, the nonpareil, the sugar-dwarf, the pickle-pea, the marrow-fat-pea, the rose or crown-pea, the round-cival-pea, the grey-pea, &c. The propagation and use of peas, are so well known as to require no description, they being common food in all parts of England; they are very nutritive but do not agree very well with weak stomachs.

*Everlasting-PEA.* See EVERLASTING and LATHYRUS.

*Sweet-PEA.* See the article LATHYRUS.

PEACE, *pax*, in its general signification, stands in contradistinction to war. See the article WAR.

PEACE, *of the king*, is that peace or security, both of life and goods, which the king promises to all his subjects, or others under his protection.

PEACH, *Persica*, in botany, a genus of fruit-trees, classed by Linnæus, with the amygdalus or almond; but although they agree in their flowers and foliage there is a very considerable difference in their fruits; the almond having a thin, tough, coriaceous covering to the stone, which splits and falls away, leaving the stones naked; whereas the peach has a thick, moist, esculent covering to its stone, which does not separate; it may therefore be necessary in this work to mention them separately. The peach tree is said to be a native of Persia; whose extreme parts (north and south) differ about ten degrees of latitude, which difference is supposed to be the cause of their several kinds being ripe at divers seasons: that is, it is imagined, that our early peaches, were natives of the northern, and our latest of the southern parts.

This tree, in England, grows to a tolerable size; is generally trained against walls, &c. being too apt to miscarry of its fruit when planted as a standard; when grown old it has a pretty thick stem, with many brittle branches, and a redish and brownish bark; the leaves are thin, oblong, acuminate, and for the most part crenated on their edges, having a bitter taste; the flowers appear in the beginning of the spring before the leaves, and

## PEA

are without pedicles, for they adhere to the tubercles of the branches, and are rosaceous, consisting each of five oblong oval petals inserted in the cup; they are of a light pink colour, and in the middle are many stamina; the flower is succeeded by a well known globular, furrowed fruit, covered with a thick soft whitish down. In England there are several sorts or varieties cultivated, as. 1. The white nutmeg peach, this is ripe in July. 2. The red nutmeg, this ripens about the beginning of August. 3. The early purple, this is ripe by the middle of August. 4. The French mignon; this is a most excellent melting peach, and ripens about the middle of August. 5. The red magdalen; this peach is ripe about the end of August. 6. The early Newington ripens the end of August. 7. The noblest, this is a fine melting peach, and ripens the end of August. 8. The chancellor, a good melting peach, and ripens the end of August. 9. The admirable; this peach parts from the stone, and ripens the beginning of September. 10. The old Newington; this peach adheres to the stone, and is reckoned one of the best sort. 11. The Portugal peach; this has a rich juice, and adheres to the stone, these ripen about the middle of September. 12. The nivette, this is a melter, and ripens in September. 13. The pavy of pomponne, is a very large fine peach, and ripens in October. 14. The Catherine, this adheres to the stone, is a high flavoured peach, and ripens in October: there are various other sorts which might be enumerated but the abovementioned being of the best and richest flavour, we think it will suffice. The French distinguish those we call peaches into two sorts, viz. pavies, and peaches; those are called peaches which separate from the stone, and those whose flesh closely adheres to the stone are called pavies; these are much more esteemed in France than the peaches, though in England the latter are preferred to the former by many persons.

The best explications for peach trees, are the south, south-east, and south-west, but they will do tolerably well on a west wall, which ripens its fruit just as those of the south are gone; they should not be planted in a cold wet soil, the fruit in such places are always watery, and insipid; the best soil for these, is fresh untried earth, which is neither too stiff nor too moist, but of a kind loamy nature; and if the earth in the borders is exhausted where the trees are intended to be planted, it should be taken away, and its place supplied with fresh; all the sorts of peaches are propagated by inoculation on plumb stocks, and trained in the nurseries for planting against walls, &c. but it is certainly best to make choice of such trees, which are of one years growth from the budding, as they will soon overtake in growth, those which are called trained trees; the best time to transplant them is in autumn, when the leaves are turned yellow, when they

they will have time to form fresh roots, before winter, and thereby be better prepared to shoot more vigorous in the spring; but the head should not be cut off at that time of planting; but if the soil is very moist, it is better to plant in the spring, just as the sap begins to be in motion: in February the tops of the trees should be cut off within four or five eyes of the place of inoculation; and when the weather becomes hot and dry, it may be necessary to water the trees: in May the young shoots will have made some progress; those which have a fore-right direction, should be displaced, and the others nailed horizontally to the wall; this must be repeated as often as it is necessary: in October, the branches should be shortened in proportion to the strength of the tree, a vigorous branch may be left nine inches or a foot long, but if the shoots are weak, half that length is sufficient; observing to train them horizontally, as the middle of the tree will easily furnish itself with branches: the second summer, they are to be managed as the first, displacing all fore-right shoots as they are produced, and nailing in the others close to the wall horizontally; but the shoots should not be shortened in the summer, unless in those places where there happens to be vacancies: in October, shorten the shoots as before directed, and the following years management, is much the same as the preceding. The time for pruning is at the abovementioned time, where the trees are planted in a dry soil; but if the land is moist, it is better to defer it till the spring.

When peach trees hasten to bear very soon, it is a sign of decay, or weakness, the best help for them is to disburthen the tree of its bloom, pruning it short, and keeping it well watered in hot weather; but when the trees are vigorous, cut out such large branches as appear to be useless, and nail in the remainder at a good length; and in making choice of shoots, always choose the middling wood as are full of swelling double buds, for those produce fruit, which the flat single ones do not, their product being wood and leaves only; the distance these trees should be planted, may be about sixteen feet: when the fruit is set and grown to the bigness of a small nut, they should be thinned, leaving them at least five or six inches asunder, for when they are permitted to remain in bunches, as they are often produced, the nourishment which should be employed wholly to the fruits designed to stand, will be equally spent amongst the whole number, a great part of which must be afterwards pulled off, so that the sooner this is done, the better it will be for the remainder; and if it should sometimes happen, that a part of those left, by any accident should be destroyed, yet the remaining ones will be much the larger, and better flavoured for it, and the trees will gain more strength; for a moderate crop of fruit, is always preferable to a great crop; for when

the trees are overcharged with fruit, it is always small, ill tasted, and the trees are generally so much weakened thereby, as not to be in a condition for bearing well for two or three years afterward: the management, &c. of nectarines being the same as of peaches, a repetition is therefore unnecessary.

PEACOCK, *Pavo*, in ornithology, a genus of birds, of the order of the gallinæ, the characters of which are these: there are four toes on each foot, and the head is ornamented with an erect crest of feathers.

PEAN, in heraldry, is when the field of a coat of arms is sable, and the powderings or.

PEAR, *Pyrus*, in botany, a genus of fruit-trees, whose flower consists of five roundish concave petals, which are inserted in the cup; the fruit is of a pyramidal form, containing five membranaceous cells, each containing a smooth, oblong, ovate seed, acuminate at the base, convex on one side and plane on the other.

Pear-trees, it is said, were originally brought from Alexandria, Numidia, Greece, &c. as appears by the names of several sorts. The fruit of some kinds ripens in the summer with us, and others are not fit for use until winter or the spring.

As the species are very numerous, we shall only mention a few of the best, viz. 1. the little musk-pear, which ripens in July; 2. the jargonelle, this is one of the best summer-pears; 3. the Windfor-pear; 4. the blanquette-pear; 5. the red orange-pear; 6. the royal-pear; 7. the summer-boncretien; 8. the rouffellet; 9. the princes-pear; 10. the summer-bergamot; 11. the autumn-bergamot; 12. the brown-beurré; 13. the monsieur John; 14. the flowered-muscat; 15. the green sugar-pear; 16. la marquise; 17. the crassan; 18. the colmar; 19. the vert-longue; 20. the virgoulé; 21. the winter-thorn; 22. the St. Germain; 23. the winter-rouffellet; 24. the Easter-bergamot; 25. the Hollands-bergamot; 26. the winter-boncretien; 27. the Chaumontelle. (The following are baking-pears) 28. the pound-pear, or black-pear of Worcester; 29. the winter citron-pear; 30. the franc-real; 31. the double flowering-pear, with many other sorts: they are all propagated by budding or grafting upon stocks of their own kind (commonly called free-stocks) or upon quince-stocks; the latter are used for low walls, dwarfs, or espaliers; and especially in wet lands, these stocks doth effectually prevent the too great luxurancy of the plant, and cause it to produce fruit much sooner than on a pear stock; but then, on the other hand, it has this evil attending it, that the tree is but short-lived, and most of the sorts of hard baking-pears are rendered stony and good for little: on the contrary, most melting soft pears are greatly improved by being grafted on quince-stocks, particularly if the soil is of a moist strong nature.

The best seasons to prune pear-trees is at the fall of

of the leaf, though it may be deferred till the spring, observing to cut out all luxuriant branches, which are known by the great distance of their buds, and to lay in no more wood than the roots may be reasonably supposed capable of supplying with sufficient juices, leaving them at a distance from each other, in proportion to the size of the fruit; such sorts whose fruit are small may be allowed five or six inches, but the larger ones must be not less than seven or eight inches asunder, always remembering to train the branches horizontally as they are produced, without topping them, by which means there will be little occasion for much pruning these trees; for it appears, that pear-trees have their bearing-buds in three different states, continually succeeding each other; the blowing-buds of three years old discover themselves at the fall of the leaf, which, whilst the fruit preceding them was growing and ripening, they were preparing to succeed them the ensuing year: these buds are produced upon cusions or spurs, and are known by their being very full and larger than the others, in a seeming swelling impatient state of breaking out into its beautiful dress of delightful bloom, which is enwrapped within it: the preparative buds of two years are of a sharp conic figure, and red russet colour, growing very near the fruitful buds before described: the junior buds of one year are very small, but full above the bark, and always break out near the buds of two years growth; to which may be added, there is a continued succession of buds in embryo, ad infinitum.

The distance pear-trees should be planted, either against walls or espaliers, should not be less than thirty feet, for if they have not room to spread on each side, it will be impossible to preserve them in good order, especially those on free stocks, for the more these trees are pruned the more they will shoot: many sorts of pears produce their blossom-buds at the extremity of the shoots, so that when they are shortened the fruit will be cut away, which cannot be avoided where the trees have not room allowed in their first planting.

The best season for planting pear-trees in a dry soil is at autumn, but if the land be moist the spring is to be preferred.

Pears, in general, are windy, and improper for weak stomachs; however, those are the best that are quite ripe and have a sweet juice, and then they are seldom hurtful, unless they are eaten to excess.

PEARL, *Margarita*, in natural history, a hard, white, shining body, usually roundish, found in a testaceous fish resembling an oyster.

Pearls, though esteemed of the number of gems by our jewellers, and highly valued, not only at this time, but in all ages, proceed only from a distemper in the creature that produces them, analogous to the bezoars, and other stony concretions in several animals of other kinds; and what the ancients imagined to be a drop of dew concentered into

a pearl in the body of the pear-fish, which they supposed rose from the bottom to the surface of the water to receive it, is nothing more than the matter destined to form and enlarge the shell, bursting from the vessels destined to carry it to the parts of the shell it would have formed, and by that means producing these little concretions.

The fish in which these are usually produced is the East-Indian pearl-oyster, as it is commonly, though not very properly, called: it has a very large and broad shell of the bivalve-kind, sometimes measuring twelve or fourteen inches over, but those of eight inches are more frequent: it is not very deep; on the outside it is of a dusky brown, and within of a very beautiful white, with tinges of several other colours, as exposed in different directions to the light. Besides this shell, there are many others that are found to produce pearls; as the common oyster, the muscle, the pinna marina, and several others, the pearls of which are often very good, but those of the true Indian berberi, or pearl-oyster, are in general superior to all. The small or seed pearls, also called ounce pearls, from their being sold by the ounce, and not by tale, are vastly the most numerous and common; but as in diamonds, among the multitudes of small ones, there are smaller numbers of larger found, so in pearls there are larger and larger kinds; but as they increase in size, they are proportionably less frequent, and this is one reason of their great price.

*Artificial PEARLS*, are made by reducing seed-pearls to a paste, by means of a chemical preparation called mercurial water, making the beads in silver moulds, boring them with a hog's bristle, and drying them in a closed glass in the sun.

Beads, in imitation of pearls, are also made of wax, and covered with the scales of several kinds of fishes.

*Mother of PEARL*, is the shell not of the pearl-oyster, but of another sea-fish of the oyster-kind. This shell on the inside is extremely smooth, and of the whiteness and water of pearl itself; and it has the same lustre on the outside, after the first laminæ or scales have been cleared off with aquafortis, and the lapidaries mill. Mother of pearl is used in inlaid works, and in several toys, as snuff-boxes, &c.

PEARL, in heraldry, in blazoning with precious stones, is the same with argent, or white.

PEARL, PIN, or WEB, in medicine, an excrescence growing in the eye. See the article UNGUIS.

PEAT, a kind of turf used for fuel in several countries. See the article Moss.

In Holland they have a way of charring peat, so that it may serve for fuel in several chemical operations; but this manner of charring is not yet known in several countries where, perhaps, peat might be found.

**PEBBLES**, *Calculi*, small stones, composed of a crystalline matter debased by earths; and hence, subject to veins, clouds, and other variegations. See **CRYSTAL**.

**PECCANT**, in medicine, a term used for those humours of the body which offend either by their quantity or quality.

**PECK**, a measure of capacity, four of which make a bushel.

**PECTIS**, in botany, a genus of plants, whose common corolla is radiated, the proper corollulæ are hermaphrodite, and funnel-shaped: the female florets which form the rays, are ligulated, and ovate; the seeds, are contained in the cup, they are solitary, linear, and crowned with a bearded down.

**PECTORAL**, an epithet for medicines good for disorders of the breast and lungs. The ordinary intention of these medicines is either to attenuate or thicken the humours of these parts, and to render them fit to be expectorated or spit out. See the article **EXPECTORANTS**.

**PECTORALIS**, in anatomy, a pair of muscles which possesses almost the whole breast, and serves to move the arm forwards.

**PECULIAR**, in the canon law, signifies a particular parish or church that has jurisdiction within itself for granting probates of wills, and administrations, exempt from the ordinary or bishop's courts.

*Court of PECULIARS*, is a court in which the affairs belonging to peculiars are transacted.

**PECUNIARY**, a term applied to the punishment of offenders by mulct or fine.

**PEDAGOGUE**, or **PÆDAGOGUE**, *παιδαγωγός*, a tutor or master to whom is committed the discipline and direction of a scholar, to be instructed in grammar and other arts.

**PEDALIUM**, in botany, a genus of plants, whose flower is monopetalous and ringent, the tube is trigonal, and the limb cut into five segments; the fruit is a reticulated nut, of a conico-tetragonal figure, containing two oblong seeds.

**PEDALS**, the largest pipes of an organ, so called because played and stopped with the foot. The pedals are made square, and of wood; they are usually thirteen in number. They are of modern invention, and serve to carry the sounds an octave deeper than the rest. See **ORGAN**.

**PEDANT**, is used for a rough unpolished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations. Dacier defines a pedant, a person who has more reading than good sense; and Malebranche describes him, as a man full of false erudition, who makes a parade of his knowledge, and is ever quoting some Greek or Latin author, or hunting back to a remote etymology: hence,

**PEDANTRY**, the quality or manner of a pedant.

**PEDESTAL**, in architecture, the lowest part of an order of columns, being that which sustains the column, and serves it as a foot or stand. See **COLUMN**.

The pedestal consists of three principal parts, viz. a square, trunk, or dye, which makes the body; a cornice, the head; and a base, the foot of the pedestal. The pedestal is properly an appendage to a column, not an essential part of it; though M. Le Clerc thinks it essential to a complete order.

There are as many kinds of pedestals as there are of orders of columns, viz. the Tuscan, Doric, Ionic, Corinthian, and Composite: some say that the height of the pedestal in each order, ought to be a third part of the whole column, comprehending the base and capital, and their proper adjuncts, as architrave, frieze, and cornice, a fourth part of the same pillar. Indeed Vignola, and most of the moderns, make the pedestal and all its ornaments in all the orders one third of the height of the column, including the base and capital; but some deviate from this rule. See the articles **BASE**, &c.

**PEDESTALS**, of *Statues*, are such as serve to support statues or figures.

**PEDICLE**, among botanists, that part of a stalk which immediately sustains the leaf of a flower or fruit, and is commonly called a foot-stalk.

**PEDICULARIS**, **RED-RATTLE**, or **LOUSE-WORT**, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is oblong and gibbous; the upper lip is helmet-shaped, erect, compressed, and emarginated; the under one is spreading, plane, semitrid, and obtuse; the fruit is an oblique, roundish, pointed capsule; with two cells, containing a number of roundish, compressed, covered seeds. This plant is of a cooling and drying nature, whence it is recommended in fistulas and other sinous ulcers.

**PEDILUVIUM**, a bathing of the feet.

**PEDIMENT**, in architecture, is a kind of low pinnacle, serving to crown an ordonnance, or finish a frontispiece, and is placed as an ornament over gates, doors, windows, niches altars, &c. being ordinarily of a triangular form, but sometimes forming an arch of a circle. The parts of a pediment are the tympanum and the cornice, which crowns it, and the entablature, which serves it as a base, or scale. Architects have taken a great deal of liberty in the form of this member; nor do they vary less as to the proportion of the pediment. The most beautiful, according to Daviler, is that where its height is about one fifth of the length of its base.

The pediment is usually triangular, and sometimes an equilateral triangle, called also a pointed pediment; it is sometimes circular, though M. Felibien observes, that we have no instance of round pediments.

pediments in the antique, besides those in the chapels of the rotundo. Sometimes its upper cornice is divided into three or four sides, or right lines: sometimes the cornice is cut or open at top, which is an abuse introduced by the moderns, particularly Michael Angelo; for the design of this part over doors, windows, &c. being chiefly to shelter those underneath from the rain, to leave it open in the middle is to frustrate its end. Sometimes the pediment is formed of a couple of scrolls or wreaths, like two consoles joined together; sometimes again it is without a base, or its lower cornice is cut out, all but what is bestowed on two columns or pilasters, and on these is raised an arch or sweep, instead of an entablature, of which Serlio gives an instance in the antique in a Corinthian gate at Folligny, in Umbria; and Daviler a modern one in the church of St. Peter at Rome.

Under this kind of pediments come those little arched corniches, which form pediments over doors and windows, supported by two consoles, instead either of entablature or columns.

Sometimes the pediment is made double, *i. e.* a less pediment is made in the tympanum of a larger, on account of some projection in the middle, as the frontispiece of the church of the great Jesus at Rome; but this is accounted an abuse in architecture, though authorized by very good buildings, as the large pavillion of the Louvre, where the caryatides support three pediments one in another: sometimes the tympanum of the pediment is cut out, or left open to let in light, as is seen under the portico of the capitol at Rome; lastly, this open pediment is sometimes triangular, and enriched with sculpture, as roses, leaves, &c. as is found in most of the Gothic churches.

M. Le Clerc observes, that the modillions in the cornice of the pediment should always answer exactly over those of the entablature. Indeed Vitruvius says, that the ancients did not allow of any modillions at all in pediments. M. Le Clerc also observes, that the cornice which serves the pediment as a base, should have no cymatium, by reason the cymatium of the rest of the entablature, when it meets the pediment, passes over it. This change of determination occasions a considerable difficulty; the cymatium in this case appearing too broad in the turn of the angle, to remedy which, architects have recourse to several expedients.

A pointed pediment may crown three arches, but a circular pediment can only crown agreeably. There should never be used more than two tympana over each other in the same frontispiece, and even where there are two, it would be proper to have the lower circular, and the upper pointed.

PEDRERO, PETERERO, or PATERERO, a small piece of ordnance, used on board ships, for the discharging of nails, broken iron, or partridge

shot, on an enemy attempting to board. See ORDNANCE.

They are generally open at the breech, and their chamber made to take out, to be loaded that way, instead of at the muzzle.

PEDUNCLE, among botanists, denotes a partial trunk, or foot-stalk, of a flower, raising the fructification, but not the leaves: the determination of peduncles respects place and manner; with regard to place they are said to be radical when they come out of the root; cauline when they are placed on the stem; rameous when they come out upon the branches; axillary when they proceed from between the leaf and stem; terminal when they terminate the branches or stem; solitary when there comes but one from the same place. With respect to manner there are either uniflorous, biflorous, triflorous, or multiflorous peduncles, and are such as bear one, two, three, or many flowers on each.

PEE, in mining, is used for the place where two veins meet and cross one another.

PEER, in general, signifies an equal, or one of the same rank and station: hence in the acts of some councils we find, these words with the consent of our peers, bishops, abbots, &c. Afterwards the same term was applied to the vassals or tenants of the same lord who were called peers, because they were all equal in condition, and obliged to serve and attend him in his courts; and peers in fiefs, because they all held fiefs of the same lord.

The term peers is now applied to those who are impannelled in an inquest upon a person for convicting or acquitting him of any offence laid to his charge; and the reason why the jury is so called, is, because by the common law, and the custom of this kingdom, every person is to be tried by his peers or equals, a lord by the lords, and a commoner by commoners.

PEER of the Realm, a noble lord who has a seat and vote in the house of lords, which is also called the house of peers.

PEERESS, a woman who is noble by descent, creation, or marriage.

If a peeress, by descent or creation, marries a person under the degree of nobility, she still continues noble: but if she obtains that dignity only by marriage, she loses it, on her afterwards marrying a commoner; yet, by the courtesy of England, she always retains the title of her nobility. No peeress can be arrested for debt or trespass; for though, on account of their sex, peeresses cannot sit in the house of lords, yet they enjoy the privileges of peers, and therefore all peeresses by birth, are to be tried by their peers.

PEGANUM, wild rue, in botany, a genus of plants, whose flower consists of five oblong oval petals, with fifteen subulated filaments, topped with oblong

## PEL

oblong erect antheræ. The fruit is a roundish, three-cornered capsule, with three cells, containing many ovate acuminated seeds.

PEGASUS, in astronomy, a constellation of the northern hemisphere, in form of a flying horse, said by different authors to contain 19, 20, and 93 stars.

PELAGIANS, a Christian sect who appeared about the latter end of the fourth, or the beginning of the fifth century.

Pelagius, the author of this sect, was born in Wales, and his name was Morgan, which in the Welch language signifies sea-born; from whence he had his Latin name Pelagius. Some of our ancient historians pretend that he was abbot of Bangor; but this is impossible, because the British monasteries were of a later date. St. Austin gives him the character of a very pious man, and a Christian of no vulgar rank: according to the same father, he travelled to Rome, where he associated himself with persons of the greatest learning and figure, and wrote his commentaries on St. Paul's Epistles, and his letters to Melania and Demetrias; but being charged with heresy, he left Rome, and went into Africa, and from thence to Jerusalem, where he settled. He died somewhere in the East, but where is uncertain. He was charged with maintaining the following doctrines: 1. That Adam was by nature mortal, and whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That new-born infants are in the same condition with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the Gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty being sufficient, &c. Pelagius's sentiments were condemned by several councils in Africa, and by a synod at Antioch.

There was also a sect of Semi-Pelagians; who, with the orthodox, allowed of original sin; but denied that the liberty of the will could be so far impaired thereby, that men could not of themselves do something, which might induce God to afford his grace to one more than another; and as to election, they held, that it depended on our perseverance; God choosing only such to eternal life, as continued steadfast in the faith.

PELECINUS, a plant, otherwise called biserrula. See the article BISERRULA.

PELICAN, *Pelicanus*, in ornithology, a genus of birds, of the order of the anseres, the beak of which is very long, crooked, and unguiculated at the extremity: its sides are not denticulated, and

## PEN

the anterior part of the head towards the throat is naked.

PELICAN, in chemistry, a kind of double glass vessel, used in distilling liquors by circulation: it consists of a cucurbit and alembic-head, with two tubes bending into the cucurbit again.

PELLETS, in heraldry, those roundles that are black, called also ogresses and gun-stones, and by the French *tortaux de sable*.

PELLICLE, among physicians, &c. denotes a thin film, or fragment of a membrane.

When any liquor is evaporated in a gentle heat, till a pellicle arise at top, it is called an evaporation to a pellicle; wherein there is just liquor enough left to keep the salts in fusion.

PELLITORY, *Parietaria*, in botany. See the article *PARIETARIA*.

PELLUCID, the same with diaphanous, or transparent. See the article *TRANSPARENT*.

PELVIS, in anatomy, the lower part of the cavity of the abdomen, thus called from its resemblance to a basin, or ewer, in Latin called *pelvis*. It is formed by the ossa ilia and ischia, the os sacrum, the os coccygis, and the ossa pubis. See the article *OSSA INNOMINATA*.

The pelvis is much larger in women than in men, to give room for the growth, &c. of the fœtus.

PELVIS of the Kidneys, is a membranaceous cavity in the kidneys, which sends out several processes called the tubuli of the pelvis, and surrounds the renal papillæ.

PEN, or PENSTOCK. See *PENSTOCK*.

PENANCE, a punishment, either voluntary or imposed by authority, for the faults a person has committed.

PENÆA, in botany, a genus of plants, whose flowers are monopetalous and campanulated, with the border cut into four segments; it hath four stamina; and the fruit is a tetragonal capsule, having four cells, each containing two oblong obtuse seeds.

PENCIL, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials; the larger sorts are made of boars-bristles, the thick ends of which are bound to a stick, bigger or less, according to the uses they are designed for: these, when large, are called brushes. The finer sorts of pencils are made of camels, badgers, and squirrels-hair, and of the down of swans; these are tied at the upper end with a piece of strong thread, and inclosed in the barrel of a quill.

All good pencils, on being drawn between the lips, come to a fine point.

PENDANT, an ornament hanging at the ear, frequently consisting of diamonds, pearls, and other precious stones.

PENDANTS, in heraldry, parts hanging down from

from the label, to the number of three, four, five, or six at most, resembling the drops in the Doric frieze. When they are more than three, they must be specified in blazoning.

**PENDANTS**, of a ship, are those streamers or long colours which are split and divided into two parts ending in points, and hung at the head of masts, or at the yard-arm ends.

**PENDANT-Feathers**, with falconers, are those feathers that grow behind the thighs of an hawk.

**PENDANTS**, among florists, the same with apices or antheræ. See **ANTHERÆ** and **STAMINA**.

**PENDENTIVE**, in architecture, the whole body of a vault suspended out of the perpendicular of the walls, and bearing against the arch-boutants: or according to Daviler, it is the portion of a vault between the arches of a dome, usually enriched with sculpture.

The pendentives are generally of brick or soft stone; but care is to be taken, that the couches, or beds of masonry, be always laid level, and in right lines proceeding from the sweep whence the rise was taken: the joints too must be made as small as possible, to save the necessity of filling them up with wood, or of using much mortar.

**PENDULOUS**, a term applied to any thing that bends or hangs downwards; thus, the flowers, whose slender stalks are not able to sustain their heads upright, are called pendulous flowers.

**PENDULUM**, in mechanics, denotes any heavy body, so suspended as that it may vibrate, or swing, backwards and forwards, about some fixed point, by the force of gravity. See the article **GRAVITY**.

The vibrations of a pendulum are called its oscillations. See the article **OSCILLATION**.

A pendulum, therefore, is any body, B, (plate LXXIII. *fig. 1.*) suspended upon and moving about a fixed point, A, as a center.

The nature of a pendulum consists in the following particulars: 1. The times of the vibrations of a pendulum, in very small arches, are all equal. 2. The velocity of the bob, in the lowest point, will be nearly as the length of the chord of the arch which it describes in the descent. 3. The times of vibration in different pendulums, AB, AC, are as the square roots of the times of their vibrations. 4. The time of one vibration is to the time of the descent, through half the length of the pendulum, as the circumference of a circle to its diameter. 5. Whence the length of a pendulum, vibrating seconds, will be found 39.2 inches nearly; and that of a half second pendulum 9.8 inches. 6. An uniform homogeneous body, BG, (*fig. 2.*) as a rod, staff, &c. which is one-third part longer than a pendulum, AD, will vibrate in the same time with it.

From these properties of the pendulum we may discern its use as an universal chronometer, or regu-

lator of time, as it is used in clocks, and such like machines.

By this instrument also we can measure the distance of a ship, by measuring the interval of time between the fire and the sound of a gun; also the distance of a cloud, by numbering the seconds, or half-seconds, between the lightning and thunder. Thus, suppose between the lightning and thunder, we number 10 seconds, then (because sound passes through 1142 feet in one second) we have the distance of the cloud equal to 11420 feet..

Again, the height of any room, or other object, may be measured by a pendulum vibrating from the top thereof. Thus, suppose a pendulum from the height of a room vibrates once in three seconds; then say, as 1 is to the square of 3. viz. 9, so is 39.2 to 352.8 feet, the height required. Lastly, by the pendulum we discover the different force of gravity on diverse parts of the earth's surface, and thence the true figure of the earth. See the article **EARTH**.

When pendulums were first applied to clocks, they were made very short; and, the arches of the circle being large, the time of vibration, through different arches, could not in that case be equal; to effect which, the pendulum was contrived to vibrate in the arch of a cycloid, by making it play between two semi-cycloids, CB, CD, (*fig. 3.*) whereby it describes the cycloid BEAD; the property of which curve is, that a body vibrating in it, will describe all its arches, great or small, in equal times.

In all that has been hitherto said, the power of gravity has been supposed constantly the same. But, if the said power varies, the lengths of pendulums must vary in the same proportion, in order that they may vibrate in equal times; for we have shewn, that the ratio of the times of vibration and descent through half the lengths is given, and consequently the times of vibration and descent through the whole length is given: but the times of vibrations are supposed equal, therefore the times of descent through the lengths of the pendulum are equal. But bodies descending through unequal spaces, in equal times, are impelled by powers that are as the spaces described, that is, the powers of gravity are as the lengths of the pendulums.

The greatest inconvenience attending this most useful instrument is, that it is constantly liable to an alteration of its length, from the effects of heat and cold, which very sensibly expand and contract all metalline bodies. See the article **HEAT**.

To remedy this inconvenience, the common method is by applying the bob of the pendulum with a screw, so that it may at any time be made longer or shorter, according as the bob is screwed upwards or downwards, and thereby the times of its vibrations kept always the same.

Again, if a glass or metalline tube, uniform

throughout, filled with quick-silver, and 58.8 inches long, were applied to a clock, it would vibrate seconds for  $39.2 = \frac{2}{3}$  of 58.8, and such a pendulum admits of a twofold expansion and contraction, viz. one of the metal and the other of the mercury, and these will be at the same time contrary, and therefore will correct each other. For, by what we have shewn, the metal will extend in length with heat, and so the pendulum will vibrate slower on that account. The mercury also will expand with heat, and since by this expansion it must extend the length of the column upward, and consequently raise the center of oscillation; so that, by this means, its distance from the point of suspension will be shortened, and therefore the pendulum on this account will vibrate quicker: wherefore, if the circumstances of the tube and mercury are skilfully adjusted, the time of the clock might, by this means, for a long course of time, continue the same, without any sensible gain or loss.

This is the invention of the late ingenious Mr. Graham, in the year 1721, who made a clock of this sort, and compared it with one of the best of the common sort for three years together, and found the errors of the former but about  $\frac{1}{3}$  part of the latter; of which the reader may see a farther account in the Philosophical Transactions, No. 392. It is what is now called Mr. Graham's quicksilver-pendulum.

In the forty-seventh volume of the Philosophical Transactions, Mr. Short gives us an account of other inventions to remedy the same inconvenience. Mr. John Harrison, of Barrow, in Lincolnshire, famous for his invention of a clock to find the difference of longitude at sea, without having the least knowledge of what Mr. Graham had done before him, made several experiments upon wires of different metals, in order to find their different degrees of expansion and contraction. He thought, that by a proper combination of wires, of two different metals, differing considerably in their expansion and contraction, he might be enabled to keep the center of oscillation of a pendulum always at the same distance from the point of suspension.

In consequence of these experiments, he made a pendulum consisting of one steel wire, at the end of which is the bob or weight; and on each side of this wire, four wires alternately brass and steel, so disposed and contrived as to raise the pendulum by the same quantity that it is lengthened by heat, and to let down the pendulum in the same proportion as it is raised by cold.

Mr. Harrison, in his first machine for measuring time at sea, likewise applied this combination of wires of brass and steel, to prevent any alterations by heat and cold. And in the two machines or clocks he has since made for the same purpose, a like method of guarding against the irregularities arising from this cause is used.

Mr. Graham also made a pendulum consisting of three bars, one of steel between two of brass, and the steel bar acted upon a lever, so as to raise the pendulum, when lengthened by heat, and to let it down when shortened by cold; but he found this clock liable to sudden starts and jerks in its motion.

The ingenious Mr. Ellicott, in the same volume of the Transactions, describes a pendulum of his invention, composed of brass and iron, with the method of applying it, so as to avoid the many jerks to which the machine might be liable.

But besides the irregularities arising from heat and cold, pendulum-clocks are liable to others from friction and foulness; to obviate which, Mr. Harrison has several excellent contrivances, whereby his clocks are almost entirely free from friction, and never need be cleaned. See the article FRICTION.

**PENETRATION**, *Penetratio*, the act whereby one thing acts upon another, or takes up the place already possessed by another.

**PENGUIN**, in ornithology, a name given to a species of the alca, with eight furrows on the beak, and a white spot before the eye. It is a very large and singular bird, equal to the common goose in size; the head is large, and flattened on the crown; the eyes are pretty large, and their iris grey with a tinge of yellow: the beak is of a kind of triangular figure, compressed at the sides, and a little hooked just at the extremity: the wings and tail are short, the feet stand backward, and the toes are connected by a membrane.

**PENINSULA**, in geography, a portion or extent of land, joining to the continent by a narrow neck, or isthmus; the rest being encompassed with water.

**PENIS**, the yard, in anatomy, the primary organ of generation in man; being called also mentula, virgo, priapus, and by a multitude of other names.

**PENITENCE**, *Penitentia*, properly signifies the same with repentance; but is also used for the discipline, or punishment, more usually called penance.

**PENITENTS**, an appellation given to certain fraternities of penitents, distinguished by the different shape and colour of their habit.

**PENNON**, or **PENON**, a kind of standard, with a long tail, anciently belonging to a simple gentleman. It is opposed to the banner, which was square.

**PENNY**, an ancient silver-coin, which, though now little used, was the only one current among our Saxon ancestors. See the article COIN.

**PENNY-EARTH**, in agriculture, denotes a hard, loamy, or sandy earth, with a large proportion of sea-shells intermixed with it.

**PENNY-ROYAL**, *Pulegium*, in botany, a plant having a perennial, creeping, fibrous root, with square

# P E N

square stalks, some of which grow upright, and others creep on the ground, putting out roots at every joint, whereby it spreads and propagates very fast; the leaves are oval, and come out from the joints of the stalks in pairs, opposite; their smell is agreeable, but strong, and the taste is hot: the flowers proceed from just above the leaves at each joint, and are disposed in whorles; they are of a pale purple, small, and helmet-shaped on the upper lip, but cut into three unequal segments on the lower one; they are succeeded by four small seeds, placed in the bottom of the cup. It flowers in July and August, at which time it should be gathered for use.

This plant is of a very subtle and penetrating nature, and is therefore aperitive, discutient, and carminative; it is an excellent pectoral, and given with great success in asthma, and all difficulties of breathing; some likewise recommend its application outwardly, in pains of the head; a distilled water of this plant, and also an oil, is kept in the shops for medicinal uses.

This plant is held as a species of mentha, or mint, by Tournefort and Linnaeus.

**PENNY-WEIGHT**, a troy-weight, containing twenty-four grains, each of which is equal in weight to a grain of wheat, gathered out of the middle of the ear, and well dried. See **WEIGHT**.

**PENSION**, a sum of money paid annually, for services or considerations already past.

**PENSIONARY**, or **PENSIONER**, a person who has an appointment, or yearly sum, payable during life, by way of acknowledgment, charged on the estate of a prince, company, or particular person.

**Grand Pensionary**, an appellation given to the first minister of the states of Holland.

**PENSIONARY**, is also the first minister of the regency of each city in Holland.

**PENSIONER**, in general, denotes a person who receives a pension, yearly salary, or allowance.

**PENTSTOCK**, a sluice, or flood-gate, serving to retain or let go, at pleasure, the water of a mill-pond, or the like. See the article **SLUICE**.

**PENTACHORD**, an ancient musical instrument, with five strings, whence the name.

The strings were of bullocks leather, and struck with a plectrum made of goats-horn.

**PENTACROSTIC**, in poetry, a set of verses so disposed as that there are always five acrostics of the same name, in five divisions of each verse. See the article **ACROSTIC**.

**PENTAGON**, in geometry, a figure of five sides and five angles.

In fortification, pentagon denotes a fort with five bastions.

**PENTRAGRAPH**, or **PARALLELOGRAM**, an instrument whereby designs of any kind may be copied in what proportion you please, without being skilled in drawing.

# P E N

**PENTAMETER**, in ancient poetry, a kind of verse consisting of five feet, or metres; whence the name.

The two first feet may be either dactyls or spondees, at pleasure; the third is always a spondee, and the two last anapests.

**PENTANDRIA**, the name of the fifth class in the Linnæan system of botany; it comprehends all those plants whose flowers are hermaphrodite; each containing five stamina, or male parts of generation. To this class belong the vine, gooseberry, curran, primrose, borage, nightshade, flax, with many other genera.

**PENTAPETALOUS**, an appellation given to flowers that consist of five petals or leaves.

**PENTAPETES**, in botany, a genus of plants, whose flower hath five oblong patent petals, and fifteen linear stamina, joined in a tube at their base, five of which are larger, coloured, and castrated; the antheræ of the others are oblong and erect: the fruit is an ovate ligneous capsule, with five cells, containing a number of oblong compressed seeds.

There is but one known species belonging to this genus, which is a native of India; the flowers are of a fine scarlet, and with us they blow from July to September, in succession: the whole plant is annual, and raised from seeds on a hot-bed in the spring.

**PENTASTICH**, *πενταστιχον*, in poetry, a stanza, or division of a poem, consisting of five verses; whence the name.

**PENTASTYLE**, in architecture, a building wherein there are five rows of columns. See the article **COLUMN**.

**PENTATEUCH**, *πεντατευχος*, an appellation given to the first five books of the Old Testament, viz. Genesis, Exodus, Leviticus, Numbers, Deuteronomy.

**PENTECOST**, a solemn festival of the Jews, so called because it was celebrated on the fiftieth day after the sixteenth of the month Nisan, which was the second day of the passover.

The feast of pentecost was instituted in memory of the law's being given, on the fiftieth day after the Israelites came out of Egypt.

It was on the feast of pentecost that the Holy Ghost miraculously descended on the apostles. See **WHITSUNDAY**.

**PENTHEMIMERIS**, in ancient poetry, a part of a verse consisting of two feet and a long syllable.

**PENTHORUM**, in botany, a genus of plants whose flower hath sometimes no petals, but often five, which are linear, small, and placed in the edge of the cup; the stamina are ten setaceous persistent filaments, topped with roundish deciduous antheræ; the fruit is a quinquefid capsule, containing a great many very small seeds.

**PENULTIMA**, or **PENULTIMATE SYLLABLE**, in grammar, denotes the last syllable but

one of a word; and hence the anti-penultimate syllable is the last but two, or that immediately before the penultima.

**PENUMBRA**, in astronomy, a partial shade observed between the perfect shadow and the full light in an eclipse.

It arises from the magnitude of the sun's body; for were he only a luminous point, the shadow would be all perfect: but by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole body of the sun, does yet receive rays from a part thereof. See the article **ECLIPSE**.

**PEONY**, in botany, see **PÆONIA**.

**PEPASMUS**, in medicine, denotes the digesting and concocting of morbid humours.

**PEPASTIC**, or **PEPTIC**, in physic, are medicaments of the consistence of an emplaster, for bringing humours to a head, and disposing them to maturation.

**PELPIS**, water purslain, in botany, a genus of plants, whose flower hath six ovate very small petals, with six short stamina: the fruit is a hard shaped capsule with two cells, containing a number of small three-cornered seeds.

**PEPO**, the **POMPION**, in botany, is comprehended by Linnæus among the cucurbita. See the article **CUCURBITA**.

**PEPPER**, Piper, in botany, a shrub, whose root is small, fibrous, tough, and blackish, from which arises many shoots that are tough, flexible, green, and woody, laying on the ground, unless propped up; they have several knots or joints, at each of which the leaves are alternately disposed; these are of a roundish form, two or three inches broad, and four long, terminating in points; the texture is thick and firm, and on the upper part they are of a shining dusky green, but beneath of a light green, and have short thick pedicles: the flowers grow in spikes, closely covered, with very small apetalous flowers without filaments; the antheræ are two in number, of a roundish form, and opposite to the root of the germen, which is large and oval, and crowned with a triple prickly stigma: the fruit is a roundish unilocular berry, containing one globose seed, which is green at first, and red when ripe, but in drying they grow black and wrinkled. It comes from Malabar, Java, Sumatra, and other parts of the East-Indies. This kind of pepper is of common and general use, and is every where employed as a spice to create an appetite, and help digestion.

Another sort of pepper, called Long Pepper, is an upright dried fruit, about an inch or an inch and a half long; it is oblong, round, cylindraceous, and, as it were, streaked with spiral lines, with tubercles placed in the form of a net; within it is divided into several small cells, containing each a small round seed, blackish without, but whitish within, with an acrid, hot, bitterish taste: long

pepper is commonly pickled, and is in high esteem among some. It is very good for cold, phlegmatic constitutions.

When the rind of black pepper is taken off it appears white, and is the only sort brought to us by the name of white pepper, though some botanical authors give us an account of a species, whose fruit is naturally white, however, there is said to be no difference between the plants that produce them, except in the colour of the fruit: it is now very rare, and only to be found in certain places of Malabar and Malacca. They have all much the same virtues, for they heat, dry, attenuate, resolve, open and strengthen relaxed fibres of the viscera, and by exciting an oscillation therein, refresh the spirits, divide gross humours, and encrease the circulation of the blood. In the East-Indies they have a way of preserving the common and long pepper in vinegar, and eating them afterwards at meals.

**Jamaica PEPPER**, *Pimenta*, in botany. See the article **PIMENTA**.

**Water-PEPPER**, in botany. See the article **POLYGONUM**.

**PEPPER-MINT**, in botany. See the article **MINT**.

**PERAMBULATOR**, in surveying, an instrument for measuring distances, called also pedometer, way-wiser, and surveying-wheel.

It consists of a wheel, *AA*, (plate **LXXIII. fig. 4.**) two feet seven inches and a half in diameter; consequently, half a pole, or eight feet three inches in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, and divided into eight teeth; which, upon moving the wheel round, fall into the teeth of another nut *c* (*fig. 5.*) fixed on one end of an iron rod *Q*; and thus turns the rod once round, in the time the wheel makes one revolution. This rod, lying along a groove in the side of the carriage of the instrument, under the dotted line, has at its other end a square hole, into which is fitted the end *b* of a small cylinder *P*. This cylinder is disposed (*fig. 6.*) under the dial-plate of a movement, at the end of the carriage *B*, in such a manner as to be moveable about its axis; its end *a* is cut into a perpetual screw, which falling into the thirty two teeth of a wheel perpendicular thereto, upon driving the instrument forward, that wheel makes a revolution each sixteenth pole. On the axis of this wheel is a pinion with six teeth, which, falling into the teeth of another wheel of sixty teeth, carries it round every hundred and sixtieth pole, or half a mile.

This last wheel, carrying a hand or index round with it over the divisions of a dial-plate, whose outer limb is divided into one hundred and sixty parts, corresponding to the one hundred and sixty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion, containing twenty teeth, which, falling into the teeth

## P E R

teeth of a third wheel, which hath forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel, having seventy-two teeth, drives it once round in twelve miles.

This fourth wheel, carrying another index over the inner limb of the dial-plate, divided into twelve for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as twelve miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and observing the hands, has the same effect as dragging the chain, and taking account of the chains and links. Its advantages are its handiness and expedition; its contrivance is such, that it may be fitted to the wheel of a coach, in which state it performs its office, and measures the road without any trouble at all.

**PER ARSIN ET THESIN**, in music: *Per arsin*, in a song, counterpoint, figure, &c. is when the notes ascend from grave to acute; and *per thesin*, when they descend from acute to grave.

**PERCA**, the perch, in ichthyology, a genus of the acanthopterygious order of fishes, the characters of which are, that the branchiostegic membrane on each side contains seven bones, and the back has one or two fins.

Besides the common perch, this genus comprehends the lucius and lucioperca. See the articles **LUCIUS** and **LUCIOPERCA**.

The perch is distinguished by several transverse streaks, and by having the belly-fins red: it grows in some places to a foot and a half in length, and is considerably thick in proportion; but its more usual size is eight or nine inches in length: its nostrils are large and patulous, and nearer the eyes than the extremity of the snout.

**PERCEPTION**, in logic, the first and most simple act of the mind, whereby it perceives or is conscious of its ideas. See the article **IDEA**.

In bare perception, the mind is for the most part only passive; yet impressions made on the senses cause no perception, unless they are taken notice of by the mind, as we see in those who are intently busied in the contemplation of certain objects. It ought also to be observed, that the ideas we receive by perception are often altered by the judgment, without our taking notice of it; so that we take that for the perception of our senses, which is but an idea formed by the judgment: thus, a man who reads, or hears, without attention, takes little notice of the characters or sounds, but of the ideas ex-

## P E R

cited in him by them. See the article **JUDGMENT**.

The faculty of perception seems to be that which constitutes the distinction between the animal kingdom and the inferior parts of nature. Perception is also the first step towards knowledge, and the inlet of all the materials of it; so that the fewer senses a man has, and the duller the impressions that are made by them are, the more remote he is from that knowledge which is to be found in other men. See **KNOWLEDGE**.

**PERCH**, or **PEARCH**, *Perca*. See the article **PERCA**.

**PERCH**, a measure of length. See the article **MEASURE**.

**PERCUSSION**, in mechanics, the impression a body makes in falling or striking upon another, or the shock of two bodies in motion. See the article **MOTION**.

Percussion is either direct or oblique; direct, when the impulse is given in a line perpendicular to the line of contact; and oblique, when it is given in a line oblique to the point of contact. See the article **CENTER**.

**PERENNIAL**, in botany, is applied to those plants whose roots will abide many years, whether they retain their leaves in winter or not: those which retain their leaves are called ever-greens; but such as cast their leaves, are called deciduous, or perdisols. Some of these have annual stalks, which die to the root every autumn, and shoot up again in the spring; to which Jungius gives the title of *radix restibilis*.

**PERESKIA**, in botany, a trailing plant, with many slender branches beset with long white spines, produced in tufts; the leaves are roundish, very thick, and succulent; the flower is roseaceous, consisting of several petals, which are placed orbicularly: the fruit is soft, fleshy, and globular, about the size of a walnut, having tufts of small leaves on it, and contains many flat roundish seeds, included in a whitish mucilaginous pulp. This plant grows naturally in some parts of the Spanish West-Indies, and is included by Linnæus among the cactus, which see.

**PERFECTION**, the state or quality of a thing perfect.

**PERFUME**, *Suffitus*, an agreeable artificial odour, affecting the organ of smelling. The generality of perfumes are made up of musk, ambergrise, civet, rose and cedar-woods, orange-flowers, jasmín, jonquils, tuberoses, and other odoriferous flowers: those drugs commonly called aromatics, such as storax, frankincense, benzoin, cloves, mace, &c. enter the composition of a perfume: some are also composed of aromatic herbs or leaves, as lavender, marjoram, sage, thyme, hyssop, &c.

Perfumes were antiently very much in use; but

since people are become sensible of the harm they do the head, they are generally diffused among us; however they are still common in Spain and Italy.

PERFUMES, in pharmacy, are topical or external remedies, composed of certain powders and gums, which being mixed together, and thrown on the coals, produce a vapour and smoke of great use in several diseases. There are dry perfumes made up in troches, pills, &c. of olibanum, mastic, olives, &c. and moist viscous ones mixed with the juices of herbs.

PERIAGOGUE, or PERIBOLE, in rhetoric, is used where many things are accumulated into one period which might have been divided into several.

PERIANTHIUM, in botany expresses that sort of cup of a flower which either consists of several leaves, or else of one leaf divided into several segments, and surrounds the lower part of the flower.

PERICARDIUM, in anatomy, a membranaceous bag, loosely including the heart, and situated in the middle and lower part of the thorax, between the two lobes of the lungs. See HEART.

PERICARPIUM, among botanists, a case or covering for the seeds of plants, and is the germen of the pistillum enlarged; it is defined by Linnæus as an entrail of the plant big with seeds, which it discharges when ripe; and is distinguished according to the circumstances that attend it by the following appellations: 1. A capsule. 2. A pod. 3. A legumen. 4. A conceptacle. 5. A drupe. 6. An apple. 7. A berry. 8. A nut. 9. A strobilus. See the articles CAPSULE, POD, &c.

PERICRANIUM, in anatomy, a thick solid coat, or membrane covering the outside of the cranium or skull.

PERIDROME, *Peridromus*, in ancient architecture, the space, gallery, alley, or the like, in a periptere, between the columns and the wall.

PERIGÆUM, PERIGEE, in astronomy, that point of the sun's or moon's orbit, wherein they are at their least distance from the earth, in which sense it stands opposed to apogee. See APOGEE.

In the antient astronomy, perigee denotes that point in a planet's orbit, wherein the centre of its epicycle is at the least distance from the earth.

PERIHELIIUM, in astronomy, that point of a planet's, or comet's orbit, wherein it is in its least distance from the sun; in which sense it stands in opposition to aphelium.

The antient astronomers, on account of their supposing the earth in the center of the system, instead of this term used that of perigæum.

PERIMETER, in geometry, the bounds or limits of any figure or body.

The perimeter of surfaces or figures are lines, those of bodies are surfaces. In circular figures, instead of perimeter, we say circumference, or periphery.

PERINÆUM, or PERINEUM, in anatomy, the space between the anus and the parts of generation, divided into two equal lateral divisions, by a very distinct line, which is longer in males than in females.

PERIOD, in astronomy, the time taken up by a star or planet in making a revolution round the sun; or the duration of its course till it return to the same point of its orbit.

PERIODS, in chronology, denotes a revolution of a certain number of years, or a series of years, whereby, in different nations, and on different occasions, time is measured; such are the following.

*Calippic PERIOD*, a system of seventy-six years.

The calippic period comprehends 48 common years, and 28 intercalary ones, 940 lunations, and 22759 days.

*Dionysian PERIOD*, or *Victorian PERIOD*, a system of 532 lunæ-solar and Julian years, which being elapsed, the characters of the moon fall again upon the same day and feria, and revolve in the same order, according to the opinion of the antients.

This period is otherwise called the great paschal cycle, because the Christian church first used it, to find the true time of the pascha, or Easter. The sum of these years arise by multiplying together the cycles of the sun and moon. See the article EASTER.

*Hipparchus's PERIOD*, a system of 304 years, both lunar and solar, which being elapsed, Hipparchus thought that the reckoning by the lunar motion would coincide again with the solar measures. This period comprehends 3760 lunar months, or 111039 days; the sum of which arises from the multiplication of the calippic period by 4, subtracting unity from the product.

*Julian PERIOD*. See JULIAN.

*Metonic PERIOD*, that invented by Meton, being the same with the cycle of the moon. See the article CYCLE.

PERIOD, in grammar, denotes a small compass of discourse, containing a perfect sentence, and distinguished at the end by a point, or full stop, thus (.); and its members or divisions marked by commas, colons, &c. See the articles POINT and SENTENCE.

PERIOD is also used for the character (.) where-with the periods of a discourse are terminated, or expressed, being commonly called a full stop or point. See the article PUNCTUATION.

PERIOD, in numbers, a distinction made by a point, or comma, after every sixth place or figure; and is used in numeration for the readier distinguishing and naming the several figures or places.

*PERIOD of a Disease*, in medicine, is the time betwixt the access of one fit, or paroxysm, and that of the next, including the entire exacerbation, decline,

eline, and intermission, or remission. These, in some disorders, are very regular and constant, as in intermitting fevers; but in chronical disorders, more irregular and uncertain, as in epilepsies; hence such diseases are called periodical.

**PERIODIC**, or **PERIODICAL**, something that terminates or comprehends a period: such is a periodical month, being the space of time wherein the moon dispatches her period; a periodical disease, &c. See **MONTH**, **DISEASE**, **PERIOD**, &c.

**PERIOECI**, *περιοικοι*, in geography, such inhabitants of the earth, as have the same latitudes, but opposite longitudes; or live under the same parallel, and the same meridian, but in different semicircles of that meridian, or in opposite points of the parallel. These have the same common seasons throughout the year, and the same phenomena of the heavenly bodies; but when it is noon day with the one, it is midnight with the other; there being twelve hours between them in an east or west direction. These are found on the globe, by the hour index, or by turning the globe half round, that is 180 degrees either way.

**PERIOSTEUM**, or **PERIOSTIUM**, in anatomy, a nervous vasculous membrane, endued with a very quick sense, immediately surrounding, in every part, both the internal and external surfaces of all the bones in the body, excepting only so much of the teeth as stand above the gums, and the peculiar places on the bones, in which the muscles are inserted. It is hence divided into the external and internal periosteum; and where it externally surrounds the bones of the skull, it is called the pericranium.

**PERIPATETIC PHILOSOPHY**, that system taught and established by Aristotle, and maintained by his followers, the peripatetics, called also Aristotelians.

The greatest and best part of Aristotle's philosophy, he is said to have borrowed from his master Plato. Serranus affirms confidently, and says that he is able to demonstrate it, that there is nothing exquisite in any part of Aristotle's philosophy, dialectics, ethics, politics, physics, or metaphysics, but is found in Plato: and of this opinion are many of the ancient authors, Clemens Alexandrinus, &c. Aristotle's philosophy preserved itself in *puris naturalibus*, a long time, none of his followers or commentators having dared to make any innovation therein, till the beginning of the thirteenth century, when it began to be new modelled. A reformed system of peripateticism was first introduced into the schools in the university of Paris, from whence it soon spread throughout Europe, and has subsisted in the universities to this day, under the name of school philosophy; the foundation whereof is Aristotle's doctrine frequently misunderstood, and oftener misapplied: but of these, at different times, have sprung several branches, as the Thomists,

Scotists, nominalists, &c. See the articles **THOMISTS**, &c.

**PERIPETIA**, *περιπέτεια*, in the drama, that part of a tragedy, wherein the action is turned, the plot unravelled, and the whole concludes. See the article **CATASTROPHE**.

The qualities of the peripetia are, that it be probable and necessary; in order to which it must be the natural result, at least the effect of the foregoing action, or of the subject itself, and must not start from any foreign or collateral cause. The peripetia is sometimes induced by remembrance or discovery, and sometimes without any discovery.

**PERIPHERY**, in geometry, the circumference of a circle, ellipses, or any other regular curvilinear figure. See the article **CIRCUMFERENCE**, **CIRCLE**, &c.

**PERIPHRAISIS**, in rhetoric, the same with circumlocution. See the article **CIRCUMLOCUTION**.

**PERIPLOCA**, climbing dog's-bane, in botany, a genus of plants, whose flower is plane, monopetalous, rotated, and cut into five narrow segments, which are emarginated; it hath a small nectarium going round the center of the petal, and five incurved filaments which are shorter than the corolla: the stamina are short, and topped with erect antheræ, which join in a head: the fruit consists of two large, oblong, ventricose follicles, each formed of a single valve, having one cell, which contains a number of imbricated seeds crowned with down: the receptacle is longitudinal and hairy.

**PERIPNEUMONY**, in medicine, an inflammation of the lungs, attended with a weight in the lungs, a difficulty of breathing, and an oppression of the breast, with a purulent spitting, and a fever accompanied with a cough. When the inflammation affects both the lobes, and the whole body of the lungs, the case is desperate.

The peripneumony is distinguished into two kinds; one of which has its seat at the extremity of the pulmonary artery, and is called the true peripneumony; and the other is situated in the bronchial arteries, and is called the spurious or bastard peripneumony.

The true peripneumony is often cured by a critical resolution and concoction of the morbid matter, which is either attenuated, so as to be returned into the channels in the common course of circulation; or expectorated by coughing; which may be easily known by an abatement of the symptoms, and the patient's falling into gentle breathing sweats.

Copious bleeding is the most effectual remedy in the beginning of this disease; but not so proper when expectoration goes on successfully, because it sometimes suppresses it, and in that case sudorifics thicken the matter which is expectorated. The motions of nature ought to be followed: the aliment ought to be more slender and thin than in any other inflammatory disease whatsoever; common  
when

Whey is sufficient to preserve the strength of the patient; relaxing aliments are proper, of which barley, and all its preparations, are the best. Diuretics that have not much acrimony are useful; and for this intention, an infusion of fennel-roots in warm water, with milk, is good. If nature relieves by a diarrhoea, without sinking the strength of the patient, it ought to be promoted by emollient clysters. But if the patient is neither relieved nor dies in eight days, the inflammation will end in a suppuration; and an abscess of the lungs, and sometimes in some other part of the body: in this case bleeding must be forborne; the diet must be mild, soft, inassuating, and more plentiful; and repid vapours should be taken into the lungs, from decoctions of proper ingredients. When, by the symptoms and time, the imposthume may be judged to be ripe, the vapour of vinegar, and any thing that creates a cough, are proper; for the sooner it is broke, the less danger will the lungs be in. In this state, which is not absolutely desperate, the aliment ought to be milk, and the drink milk and barley-water, with gentle anodynes, and the patient may have some rest.

*Spurious or Bastard PERIPNEUMONY*, a disease of the lungs, which generally arises from a heavy pituitous matter generated in the blood, and cast upon the lungs.

In this disorder, the patient is hot and cold by turns, is giddy upon the least motion, and complains of a rending pain of the head whenever he coughs; he vomits up every thing that he drinks; the urine is turbid and red, and the whole thorax full of pain. To remedy which, he should be let blood from a large orifice; and then give him the following clyster, which must be repeated daily, till the symptoms evince that the lungs are relieved: take of honey, three ounces; of nitre, one dram; one yolk of an egg; and eight ounces of barley-water; make them into a clyster. Let the patient's diet be very slender, such as weak broths, sharpened a little with orange or lemon-juice; and he may drink a weak mixture of honey and water: the steams of warm water may be taken in at the mouth, and the following decoction may be given him: take of the roots of fennel, two ounces; of the roots of grass, four ounces; of the leaves of pellitory, and agrimony, each a handful and a half; of the bruised seeds of white poppy, one ounce; and of liquorice, one ounce and a half; boil them, for a quarter of an hour, in two pints and a half of water: of which, let the patient drink two ounces every two hours. Likewise, let his legs and feet be bathed, and large blisters applied.

**PERIPTERE**, in the ancient architecture, a building encompassed on the outside by a series of insulated columns, forming a kind of portico all around; such were the portico of Pompey, the sepulchre of Severus, and the basilica of Antoninus.

The peripteres were properly temples, which had columns on all the four sides, by which they were distinguished from the prostyle and amphiprostyle, the last of which had no columns before, and the first none on the sides.

M. Perault observes, that periptere, in the general sense of the word, is the name of a genus, including all the species of temples, which have porticos of columns all around, whether the columns be diptere, or pseudo-diptere, or simply periptere, which is a species that bears the name of a genus, and which has its columns distant from the wall, the breadth of an intercolumniation.

**PERISCHII**, in geography, the inhabitants of either frigid zone, between the polar circles and the poles; where the sun, when in the summer signs, moves only round about them, without setting, and consequently their shadows, in the same day, turn to all the points of the horizon.

**PERISKYTISM**, in ancient surgery, an incision made under the coronal suture, reaching from one temple across to the other, penetrating to the bone of the cranium.

**PERISTALTIC**, in medicine, a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres, of which the fleshy coats of the intestines are composed; by means whereof the chyle is driven into the orifices of the lacteal veins, and the faeces are protruded towards the anus. See **CHYLIFICATION**.

When this motion comes to be depraved, and its direction changed, so as to proceed from below upwards, it produces what is called the illiac passion. See the article **ILLIAC PASSION**.

**PERISTAPHYLINUS**, in anatomy, a name which some give to a muscle of the uvula, more properly denominated pterygostaphylinus. See the article **UVULA** and **PTERYGOSTAPHYLINUS**.

**PERISTYLE**, in ancient architecture, a building encompassed with a row of columns on the inside: such was the hypæthre temple of Vitruvius, and such are now some basilicas in Rome, several palaces in Italy, and most cloisters of religious.

Peristyle is also used, by modern writers, for a range of columns, either within or without a building: thus we say, the Corinthian peristyle of the portal of the Louvre, &c.

**PERISTYOLE**, in medicine, the interval of rest between the two motions of the heart, viz. that of the systole, or contraction, and that of the diastole, or dilatation.

**PERITONÆUM**, in anatomy, is a thin, smooth, and lubricous membrane, investing the whole internal surface of the abdomen, and containing most of the viscera of that part, as it were in a bag.

**PERITROCHUM**, in mechanics, denotes a wheel, or circle, concentric with the base of a cylinder,

linder, and moveable together with it, about an axis. See *Axis in Peritrochio*.

**PERJURY**, in law, the crime of swearing falsely, where a lawful oath is administered by one in authority, in a matter relating to the issue or cause in question, whether it be a person's own wilful act, or done by the subordination of others.

**PERIWINKLE**, in the history of shell-fish, a species of *buccinum*. See **BUCCINUM**.

**PERIWINKLE**, *Vinca*, in botany. See the article **VINCA**.

**PERMANENT**, in general, something that continues the same, whether in nature or situation, and other circumstances: thus, air generated by fermentation, is said to be permanent, because it continues to shew all the natural properties of the common air.

Thus, also, those cups of flowers are called permanent, which remain after the flower-leaves are fallen.

**PERMEABLE**, a term applied to bodies of so loose and porous a structure, as to let something pass through them.

**PERMUTATION**, in commerce, the same with bartering. See **BARTERING**.

In the canon-law, permutation denotes the actual exchange of one benefice for another.

**PERMUTATION of Quantities**, in algebra, the same with combination.

**PERNIONES**, **CHILBLAINS**, or **KIBES**, in surgery, a name given to those tumours which happen in the hands and feet, from violent cold. See the article **COLD**.

Chilblains are accompanied with inflammation, heat, redness, pricking pain, and immobility of that limb: sometimes they are of a livid or leaden colour, and sometimes they break out with scabs, or else with chops or slits, which afterwards penetrate deeper, and become ulcerous. The humour which they discharge is a little foetid, and pretty much resembles pus or sanies; and they terminate in either disperison, suppuration, or gangrene, and sphacelus.

While the chilblains are yet tumified and red, and the part retains its sense and motion, without any great heat and pain, the disorder is then of the mildest kind; on the contrary, when they are livid, occasion the skin to become stiff and insensible, or excite pricking pains therein, there is then danger of a worse consequence, lest it should degenerate into a gangrene, or at least a deep exulceration.

There being no room to doubt but that cold is the cause of chilblains, it readily follows, that the cure must consist chiefly in restoring the blood to its former fluidity, and free circulation, as soon as possible; for which purpose, an external as well as internal treatment is necessary.

In the external treatment, the patient being exposed in a temperate air, should, according to Heister,

exercise his limbs as much as possible, in order to advance him still to a greater warmth or heat; but when he is too weak to exercise himself, it will be proper to bathe the parts affected with snow, or cold water; after which, when the limb becomes sensible, comfortable medicines may be applied, such as spirit of wine, either pure or with theriaca, rock-oil, balsam of sulphur, &c. When the parts affected have been well rubbed or bathed with these, the patient may then be advanced towards the fire, or be put to bed, endeavouring afterwards to excite a gentle sweat.

In the internal treatment, great service will be had from a few glasses of hot wine, wherein has been boiled some cinnamon and sugar; though it may not be improper to give with this, alternately, a small quantity of some sudorific mixture.

If the wine be not at hand, good ale, boiled with cinnamon, cloves, and sugar, may well enough supply its place. It should be continued so as to keep up a sweat for a whole hour, for half an hour, or according to the several circumstances: but if the disorder is much slighter, this method is then not so directly necessary; it may then be laid aside: though, in the opinion of Heister, it is much preferable to any other method. When chilblains tend to a suppuration, then it is proper to treat them like other abscesses. See the article **ABSCESS**.

If a patient has before been troubled with chilblains, which are used to return every year in the winter, the preservative against the disorder is to anoint the parts affected with petroleum, or oil of turpentine, before and after the severity of the winter comes on; but when the disorder has begun to shew itself again by tumour, inflammation, and pain, the heel or finger may be wrapped up in a swine's bladder, dipped in the fore-mentioned oil, and the cold itself should always be carefully avoided by proper cloths, or coverings.

**PERORATION**, *Peroratio*, in rhetoric, the epilogue, or last part of an oration, wherein what the orator had insisted on through his whole discourse, is urged afresh with greater vehemence and passion.

The peroration consists of two parts. 1. Recapitulation, wherein the substance of what was diffused throughout the whole speech, is collected briefly, and cursorily, and summed up with new force and weight. 2. The moving the passions, which is so peculiar to the peroration, that the masters of the art call this part *sedes affectuum*. The passions to be raised are various, according to the various kinds of oration. In a panegyric, love, admiration, emulation, joy, &c. In an invective, hatred, contempt, &c. In a deliberation, hope, confidence, or fear. The qualities required in the peroration are, that it be very vehement and passionate, and that it be short; because, as Cicero observes, tears soon dry up.

## P E R

**PERPENDICULAR**, in geometry, a line falling directly on another line, so as to make equal angles on each side; called also a normal line. See **ANGLE**.

**PERPENDICULAR to a Parabola**, is a right-line cutting the parabola in the point in which any other right-line touches it, and is also itself perpendicular to that tangent.

**PERPENDICULARITY OF PLANTS**, in natural history, a quality observed in all plants, which, though they rise a little crooked, yet the stems shoot up, and the roots sink down, as much as possible in a perpendicular direction.

This curious phenomenon was first observed by M. Dodart, who published an express essay on the affectation of perpendicularity observed in the stems or stalks of all plants, in the roots of many, and even in their branches. He observes, that such plants, or parts of plants, as by the declivity of the soil come out inclined, or such as are diverted out of the perpendicular by any violent means, again redress and straighten themselves, and recover their perpendicularity by making a second or contrary bend, or elbow, without rectifying the first.

**PERPETUITY**, in law, is when an estate is intended to be so settled in tail, &c. that it may not possibly be undone, or made void.

**PERQUISITE**, in law, is any thing gotten by a man's own industry, or purchased with his money; in contradistinction to what descends to him, from his father or other ancestors.

**PERQUISITES of Courts**, are the profits which casually accrue to a lord of the manor from his courts-baron, by fines for copyholds, escheats, heriots, amercements, &c.

**PERRON**, in architecture, the steps in the front of a building, raised before the doors of great houses, and leading to the first story, when raised above the level of the ground.

**PERRY**, a drink made of pears, in the same manner as cyder is made from apples. See the article **CYDER**.

**PERSEA**, Avocado-pear, in botany, an ever-green-tree, which grows to the height of thirty feet, and upwards; the trunk is large, smooth, and of an ash-colour; the branches are furnished with large, oblong, smooth leaves, like those of laurel, and of a deep green-colour; the flowers are produced towards the extremities of the branches, and are hexapetalous, acuminate, and spread open: the fruit is fleshy and pyramidical (about the size of one of our largest pears) inclosing a large oval seed, with two lobes, included in a thin shell.

This tree grows in great plenty in the West-Indies, and is esteemed by its inhabitants not only as a desert, but as very necessary for the support of life: the fruit alone is very insipid, for which reason they generally eat it with the juice of lemons and sugar, to give it a pungency; it is very nourishing and is

## P E R

reckoned a great incentive to ventry: it is eaten by some people with vinegar and pepper.

This plant is comprehended by Linnæus among the laurus; it is raised from seed, and requires a hot-house in this climate to preserve it.

**PERSECUTION**, is any pain or affliction which a person designedly inflicts upon another; and, in a more restrained sense, the sufferings of christians on account of their religion.

**PERSEVERANCE**, in theology, a christian virtue, by which we are enabled to persist in the way of salvation to the end.

**PERSEUS**, in astronomy, a constellation of the northern hemisphere, which, according to the catalogues of Ptolemy and Tycho, contains twenty-nine stars; but in the Britannic catalogue, sixty-seven.

**PERSIAN-WHEEL**, an engine, or wheel, turned by a rivulet, or other stream of water, and fitted with open boxes at its cogs, to raise water for the overflowing of lands, or other purposes.

It may be made of any size, according to the height the water is to be raised to, and the strength of the stream by which it is turned. This wheel is placed so, that its bottom only is immersed in the water, wherein the open boxes at its cogs are all filled, one after another, with water, which is raised with them to the upper part of the wheel's circuit, and then naturally empties itself into a trough which carries it to the land.

**PERSICA**, the peach, in botany. See the article **PEACH**.

**PERSICARIA**, arsmart, in botany, a genus of plants, whose flower is monopetalous, and cut into five spreading segments; there is no pericarpium, but the seed, which is single, roundish, and acute-pointed, is contained in the corolla, which is permanent.

There is great irregularity in this genus, some species having only five stamina, and others six or eight, and one, two, or three styles.

The persicaria orientalis is a large plant, and cultivated in our gardens; it rises to the height of eight or ten feet, where the soil is moist, and is furnished with large leaves, like those of tobacco, of a bright green, and a little hairy; the branches are terminated with spikes of flowers of pink-colour, seven or eight inches long, hanging downwards. This plant is annual, and begins to shew its flowers about the beginning of August, and makes a beautiful appearance, until the frosts in Autumn put a stop thereto. The propagation of this plant is easy, for if the seeds are suffered to shed where the plants grow, they will come up in plenty in the spring, at which time they may be transplanted where they are to remain.

The spotted arsmart sends forth stalks to the height of a foot; they are hollow, reddish, branched and jointed; the leaves are shaped like those of the peach-tree,

tree, and marked with black spots; the flowers grow in spikes, and come out in July and August. It grows wild in watery, marshy, and moist ditches, almost every where.

Another species, called by some water-pepper, and biting arsmart, grows in moist places; it is extremely hot and penetrating, insomuch that the taste is hardly tolerable; this has made it obtain in scorbutic cases, hypochondriac affections, and all disorders arising from a sluggish circulation of the fluids; and its distilled water, given in two or three ounces, is accounted a specific against the gravel and stone: all authors agree, that the herb applied to old ulcers eats away proud flesh, cleanses, and dries them; applied as a cataplasm to the bruises of horses, it resolves the coagulated blood; and if wounds or ulcers are washed with the juice, the flies will never come near them.

**PERSON**, an individual substance of a rational or intelligent nature. Thus we say, an ambassador represents the person of his prince; and that in law, the father and son are reputed the same person.

**PERSON**, in dramatic poetry, the character assumed by an actor, or he who is represented by the player. Thus, at the head of dramatic pieces, is placed the dramatis personæ, or list of the persons that are to appear on the stage.

Father Bosiu observes, that in the epic and dramatic poem the same person must reign throughout; that is, must sustain the chief part through the whole piece, and the characters of all the other persons must be subordinate to him.

**PERSON**, in grammar, a term applied to such nouns or pronouns, as being either prefixed or understood, are the nominatives in all inflections of a verb; or it is the agent or patient in all finite and personal verbs.

**PERSONABLE**, in law, signifies the being able to maintain a plea in court; especially in the case of an alien, who may be made personable by act of parliament.

It is also used to signify a capacity to receive any thing granted or given.

**PERSONAL**, any thing that concerns, or is restrained to, the person: thus it is a maxim in ethics, that all faults are personal.

**PERSONAL ACTION**, in law, is an action levied directly and solely against the person, in opposition to a real or mixed action.

**PERSONAL GOODS**, or **CHATTELS**, in law, signifies any moveable thing belonging to a person, whether alive or dead.

**PERSONAL TYTHES**, are tythes payable out of the profits obtained by a man's personal labour and industry, as in buying, selling, handicraft, &c.

**PERSONAL VERB**, in grammar, a verb conjugated in all the three persons; thus called, in opposition to an impersonal verb, or that which has the third person only. See **IMPERSONAL VERB**.

**PERSONALITY**, in the schools, that which constitutes an individual a distinct person.

**PERSONATED-FLOWERS**, among botanists, are those which resemble the gaping mouths of certain living animals: they belong to the angiosperma order of the didynamia class, in botany: such are the snap-dragon, eye-bright, cow-wheat, rhinanthus, &c.

**PERSPECTIVE**, that branch of optics, which teaches how to represent objects on a plane superficies, such as they would appear at a certain distance and height, upon a transparent plane perpendicular to the horizon, placed between the objects and the eye.

The foundation of perspective may be thus conceived: suppose the pentagon *ABDEF* (plate LXXIII. fig. 7.) were to be represented by the rules of perspective on the transparent plane *VP*, placed perpendicularly on the horizontal plane *HR*; dotted lines are imagined to pass from the eye *C* to each point of the pentagon, as *CA*, *CB*, *CD*, &c. which are supposed in their passage through the plane *PV*, to leave their traces or vestigia in the points *a*, *b*, *d*, &c. on the plane, and thereby to delineate the pentagon *abdef*; which, as it strikes the eye by the same rays that the original pentagon *ABDEF* does, will be a true perspective representation of it.

The business of perspective, therefore, is to lay down geometrical rules for finding the points *abdef* upon the plane; and hence, also, we have a mechanical method of delineating any object very accurately.

Perspective is either employed in representing the ichnographies, or ground-plots of objects; or the scenographies, or representations of the objects themselves. See the articles **ICHOGRAPHY** and **SCENOGRAPHY**.

The horizontal line is that supposed to be drawn parallel to the horizon through the eye of the spectator; or rather, it is a line which separates the heaven from the earth, and which limits the sight. Thus *A*, *B*, (fig. 8.) are two pillars below the horizontal line, *CD*, by reason the eye is elevated above them; in fig. 3. they are said to be equal with it; and in fig. 4. raised above it. Thus, according to the different points in view, the objects will be either higher or lower than the horizontal line. The point of sight, *A* (fig. 9.) is that which makes the central ray on the horizontal line, *ab*; or it is the point where all the other visual rays, *D*, *D*, unite. The points of distance, *C*, *C*, are points set off in the horizontal line, at equal distances, on each side of the point of sight, *A*; and, in the same figure, *BB* represents the base line, or fundamental line; *EE* is the abridgment of the square, of which *D*, *D*, are the sides; *F*, *F*, the diagonal lines, which go to the points of distance, *C*, *C*. Accidental points, are those where the objects end: these may

may be cast negligently, because neither drawn to the point of sight, nor to those of distance, but meeting each other in the horizontal line; for example, two pieces of square timber, G and H (*fig. 10.*) make the points I, I, I, I, on the horizontal line; but go not to the point of sight K, nor to the point of distance C, C: these accidental points serve likewise for casements, doors, windows, tables, chairs, &c.

The point of direct view, or of the front, is when we have the object directly before us; in which case it shews us only the fore-side; and, if below the horizon, a little of the top; but nothing of the sides, unless the object be polygonous. The point of oblique view, is when we see an object aside of us, and, as it were, aslant, or with the corner of the eye; the eye, however, being all the while opposite to the point of sight; in which case, we see the object laterally, and it presents to us two sides or faces. The practice is the same in the side points as in the front points; a point of sight, point of distance, &c. being laid down in the one as well as in the other.

We shall now give such rules as are of more general use in the practice of perspective. 1. Let every line, which in the object, or geometrical figure, is straight, perpendicular, or parallel to its base, be so also in its scenographic delineation. 2. Let the lines, which in the object return at right angles from the fore-right side, be drawn scenographically from the visual point. 3. Let all straight lines, which in the object return from the fore-right side, run in a scenographic figure into the horizontal line. 4. Let the object you intend to delineate, standing on your right-hand, be placed also on the right-hand of the visual point; and that on the left-hand, on the left-hand of the same point; and that which is just before, in the middle of it. 5. Let these lines which are (in the object) equidistant to the returning line, be drawn in the scenographic figure, from that point found in the horizon. 6. In setting off the altitude of columns, pedestals, and the like, measure the height from the base line upward, in the front, or fore-right side; and a visual ray down that point in the front shall limit the altitude of the column or pillar, all the way behind the fore-right side, or orthographic appearance, even to the visual point. This rule you must observe in all figures, as well where there is a front or fore-right side, as where there is none. 7. In delineating ovals, circles, arches, crosses, spirals, and cross-arches, or any other figure in the roof of any room, first draw ichnographically, and so with perpendiculars from the most eminent points thereof, carry it up unto the ceiling; from which several points, carry on the figure. 8. The center in any scenographic regular figure is found by drawing cross lines from opposite angles: for the point where the diagonals cross, is the center. 9. A

ground-plane of squares is alike, both above and below the horizontal line; only the more it is distant above or below the horizon, the squares will be so much the larger or wider. 10. In drawing a perspective figure, where many lines come together, you may, for the directing of your eye, draw the diagonals in red; the visual lines in black; the perpendiculars in green, or other different colour, from that which you intend the figure shall be of. 11. Having considered the height, distance, and position of the figure, and drawn it accordingly, with side or angle against the base; raise perpendiculars from the several angles, or designed points, from the figure to the base, and transfer the length of each perpendicular, from the place where it touches the base, to the base on the side opposite to the point of distance; so will the diametrals drawn to the perpendiculars in the base, by intersection with the diagonals, drawn to the several transferred distances, give the angles of the figures, and so lines drawn from point to point will circumscribe the scenographic figure. 12. If in a landscape there be any standing-waters, as rivers, ponds, and the like, place the horizontal line level with the farthest sight or appearance of it. 13. If there be any house, or the like, in the picture, consider their position, that you may find from what point in the horizontal lines to draw the front and sides thereof. 14. In describing things at great distance, observe the proportion, both in magnitude and distance, in draught, which appears from the object to the eye. 15. In colouring and shadowing of every thing, you must do the same in your picture, which you observe with your eye, especially in objects lying near; but, according as the distance grows greater and greater, so the colours must be fainter and fainter, till at last they lose themselves in a darkish sky-colour. 16. The catoptrics are best seen in a common looking-glass, or other polished matter; where, if the glass be exactly flat, the object is exactly like its original; but, if the glass be not flat, the resemblance alters from the original; and that more or less, according as the glass differs from an exact plane. 17. In drawing catoptric figures, the surface of the glass is to be considered, upon which you mean to have the reflection: for which you must make a particular ichnographical draught, or projection; which on the glass must appear to be a plane full of squares, on which projection transfer what shall be drawn on a plane, divided into the same number of like squares; which though the draught may appear very confused, yet the reflection of it on the glass will be regular, proportional, and regularly composed. 18. The dioptric, or broken beam, may be seen in a tube through a crystal or glass, which hath its surface cut into many others, whereby the rays of the object are broken. For to the flat of the crystal, or water, the rays run straight; but then they break and make an angle

gle, which also by the refracted beams is made and continued on the other side of the same flat. 19. When these faces on a crystal are returned towards a plane placed directly before it, they separate themselves at a good distance on the plane, because they are all directed to various far distant places of the same. See REFLECTION and REFRACTION.

PERSPECTIVE also denotes a kind of painting frequently seen in gardens, at the ends of galleries, &c. expressly designed to deceive the sight.

PERSPECTIVE-GLASS, in optics, differs from a telescope in this: instead of the convex eye-glass placed behind the image, to make the rays of each pencil go parallel to the eye, there is placed a concave eye-glass as much before it; which opens the converging rays, and makes them emerge parallel to the eye.

The quantity of objects taken in at one view with this instrument, does not depend upon the breadth of the eye-glass, as in the astronomical telescope, but upon the breadth of the pupil of the eye.

PERSPECTIVE PLANE, is the glass, or other transparent surface supposed to be placed between the eye and the object, perpendicularly to the horizon. It is sometimes called the section, table, or glass.

PERSPIRATION, in medicine, the evacuation of the juices of the body through the pores of the skin. Perspiration is distinguished into sensible and insensible: and here sensible perspiration is the same with sweating; and insensible perspiration, that which escapes the notice of the senses; and this last is the idea affixed to the word perspiration when used alone.

PESADE, or PESATE, in the manege, is a horse's raising his fore-quarters, and bending his feet up to his body without stirring his hind-feet.

PESSARY, in medicine, a solid substance composed of wool, lint, or linen, mixed with powders, oils, wax, &c. made round and long like a finger, in order to be introduced into the exterior neck of the matrix, for the cure of several disorders incident to the uterus.

This name is also sometimes given to pieces of cork, or other matters thrust up the nostrils, &c. to prevent the entrance of strong infectious steams.

PESTILENCE, in medicine, an epidemical, contagious, and malignant disease, popularly known by the name of plague. See the article PLAGUE.

PESTILENTIAL FEVERS, such as are attended with some malignant quality, and approach to the nature of a plague.

PETAL, *Petala*, among botanists, an appellation given to the fine coloured leaves which in common compose the most conspicuous part of the flower, by which name they are conveniently distinguished from the common leaves of the plant, which are called folia.

According to the number of petals the corolla is composed of, the flower is said to be monopetalous, or containing one petal; dipetalous, when it has two; tripetalous, when three, &c. See the article FLOWER.

PETARD, in the art of war, a metalline engine, somewhat resembling a high-crowned hat.

The petard may be considered as a piece of ordnance; it is made of copper mixed with brass, or of lead with tin; its charge is from five to six pounds of powder, which reaches to within three fingers-breadth of the mouth; the vacancy is filled with tow, and stopped with a wooden tampion, the mouth being strongly bound up with cloth tied very tight with ropes. It is covered up with a madrier, or wooden plank, that has a cavity to receive the mouth of the petard, and fastened down with ropes.

Its use is in a clandestine attack to break-down gates, bridges, barriers, &c. to which it is hung; and this it does by means of the wooden plank. It is also used in countermines to break through the enemy's galleries, and give their mines vent.

The invention of petards is ascribed to the French Huguenots, in 1579, who with them took Cahors, as D'Aubigné tells us.

PETASITES, butterbur, in botany, is comprehended by Linnæus among the tussilaginos, or colts-feet. See the article TUSSILAGO.

The root of the common butterbur is celebrated for its cordial and alexipharmic virtues; and besides being aperient and detergent, is prescribed in suppressions of urine and the menses: as also in the cough, asthma, and other disorders of the breast.

PETECHIÆ, in medicine, denote spots in the skin like flea-bites, which come out in malignant fevers, hence called petechial, or spotted fevers.

PETER, or *Epistle of St. PETER*, two canonical books of the New Testament, written by the apostle St. Peter, and addressed to those Jewish converts who were scattered throughout Pontus, Galatia, &c. not only upon the persecution raised at Jerusalem, but upon former dispersions of the Jews into those places. The first of these epistles is principally designed to comfort and confirm them, under those fiery trials they were then subject to; and to direct them how to behave in the several states and relations, both of the civil and the Christian life. In the second epistle, the apostle prosecutes the same subject, to prevent their apostasy from the faith, and guard them against the corrupt principles of the gnostics, and those who scoffed at the promise of Christ's coming.

St. PETER'S DAY, a festival of the Christian church, observed on the 29th of June.

PETER-PENCE, an ancient tax of a penny on each house, paid to the pope.

It was called Peter-pence, because collected on 8 K the

the day of St. Peter *ad vincula*, and sent to Rome; whence it was also called Rome-scot, and Rome-penny.

**PETESIA**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is cylindric and longer than the cup, and the limb is cut into four roundish obtuse segments: the stamina are four subulated filaments, the length of the tube, and topped with oblong antheræ. The fruit is a globose, coronated, bilocular berry, containing a few roundish seeds.

**PETIOLE**, *Petiolum*, in botany, the slender foot-stalk which connects the leaf to the branch of a plant, whereby it is distinguished from a peduncle, which is the footstalk of a flower. Some also use the word petiole for the middle rib of a leaf; the branches thereof being called rami, and the subdivisions of these, furculi.

**PETITIO PRINCIPII**, in logic, the taking a thing for true, and drawing conclusions from it as such; when it is really false, or at least wants to be proved, before any inferences can be deduced from it.

**PETITION**, a formal supplication or request made by an inferior to a superior, especially to one having jurisdiction.

**PETIVERIA**, in botany, a genus of plants, whose flower is apetalous, only the cup being coloured red has much the appearance of such; it is cut into four linear, erect, obtuse segments, and contains six subulated stamina: the seed is single, flattened, and emarginated, and armed with a style outwardly reflexed.

**PETREA**, in botany, a plant which arises with a woody stalk to the height of fifteen or sixteen feet, which is covered with a light grey bark, sending out several long branches; these have a lighter bark than the stem, and are furnished with leaves at each joint, which on the lower part are placed by threes, but on the upper part they stand by pairs on the branches; they are about five inches long and two and a half broad in the middle, drawing to a point at each end; they are stiff, the surface rough, of a light green, having a strong midrib with several transverse veins. The flowers are produced at the ends of the branches, growing in loose bunches which are nine or ten inches long, each flower standing upon a slender peduncle about an inch long; the cup of the flower is of one leaf, deeply cut into five obtuse segments about an inch long, and are of a fine blue colour, which make them more conspicuous than the corolla, which is monopetalous and less than the cup, and of a whiter colour; when the flower is decayed, the germina becomes four oblong seeds, wrapped up in a fringed cover. This plant may be reckoned among the first class of beautiful American trees; it grows naturally in the Spanish West-Indies, and is propagated from seeds which with us must be obtained from the places

where the trees grow naturally, and should be sown on a hot bed, and when the plants are up, they should be placed singly in small pots, in good light loamy earth, and plunged into the bark bed in the hot-house, where they should constantly remain.

**PETRIFICATION**, in physiology, denotes the conversion of wood, bones, and other substances into stone.

**PETROBUSSIANS**, in church-history, a religious sect which arose in France and the Netherlands, about the year 1126, so called from their leader Peter Bruys.

They denied that children, before the use of reason, can be justified by baptism. They also condemned all places of public worship, crosses, crucifixes; and are said to have rejected the sacrament of the eucharist, and prayers for the dead.

**PETROLEUM**, also called rock-oil, or oil of petre, is an extremely subtle and penetrating fluid, and is by much the thinnest of all the native bitumens.

Petroleum is found in rivers, in wells, and trickling down the sides of hills along with little streams of water. In short, it is the most frequent of all liquid bitumens, and is perhaps the most valuable of them all in medicine. It is to be chosen the purest, lightest, and most pellucid that can be had, such as is of the most penetrating smell and is most inflammable.

It is principally used externally, in paralytic cases, and in pains of the limbs. The French give it internally in hysteric complaints, and to their children against worms; some also give it from ten to fifteen drops in wine, for suppression of the menses. These, however, are rather the practices of the common people than of the faculty.

**PETROSA OSSA**, in anatomy, a name given to the fourth and fifth bones of the cranium, called also ossa temporum, and also ossa squamosa; the substance whereof, as their first and last names express, is squamose and very hard.

**PETROSOLINUM**, parsley, in botany. See the article **PARSLEY**.

**PETUNSE**, in natural history, one of the two substances whereof the porcelain or china-ware is made. See **PORCELAIN**.

The petunse is a coarse kind of flint or pebble, the surface of which is not so smooth, when broken, as that of our common flint.

**PEUCEDANUM**, hog's-fennel, in botany, a genus of umbelliferous plants, the universal umbel is multiplex, very long and narrow, and the particular one spreads open; the general corolla is uniform, and each single flower is composed of five equal, oblong, incurved petals, which are entire; there is no pericarpium, but the fruit, which is ovate and channelled on each side, divides into two parts, containing two ovato-oblong, compressed seeds, convex on one side, with three raised furrows,

rows, and a broad membranous border indented at top. A species of this genus, which grows naturally in marshy meadows in several parts of Germany, is reckoned aperient, pectoral, and uterine; the root is the only part used; it is accounted good to clear the lungs of tough viscid phlegm, and thereby to help old coughs and shortness of breath; it likewise opens obstructions of the liver and spleen, and helps the jaundice.

PEZIZA, in botany, a genus of cryptogamous plants of the fungous kind; they are of a campanulate form, with orbiculated seeds of a convex plane figure. This genus comprehends the cyathoides of Micheli.

PHACA, in botany, a genus of plants, whose flower is papilionaceous, the vexillum is straight, ovate, and large; the wings are oblong, obtuse, and short; and the carina is short, compressed and obtuse. The fruit is an oblong inflated legumen, whose upper suture is depressed towards the under, and contains several kidney-shaped seeds.

PHÆNOMENON, *φαινόμενον*, in philosophy, denotes any remarkable appearance, whether in the heavens or on earth; and whether discovered by observation or experiments.

PHALANGIUM, spider-wort, in botany. See the article SPIDER-WORT.

PHALANX, in Grecian antiquity, a square battalion, consisting of eight thousand men, with their shields joined, and pikes crossing each other; so that it was next to impossible to break it.

PHALARIS, in botany, a genus of plants whose flower-cup consists of an uniflorous, bivalvular, membranaceous glume; the corolla is also a bivalvular glume, scarce the length of the cup; the stamina are three capillary filaments, topped with ovate antheræ; it hath one roundish compressed seed, convex on one side, and contained in the corolla.

PHALACROIDES, in botany, the same with the briza. See the article BRIZA.

PHALEUCIAN VERSE, in antient poetry, a kind of verse which consists of five feet, the first of which is a spondee, the second a dactyl, and the three last trochees.

PHALLUS, in botany, a genus of cryptogamous plants, of the fungus kind; they are smooth underneath, but above are reticulated and callous.

PHANTASY, FANCY, the same with imagination, which see.

PHARISEES, a famous sect of the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the same fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men, and therefore separated themselves from those whom they thought sinners or prophane, so as not to eat

or drink with them; and hence, from the Hebrew word *pharis*, which signifies to separate, they had the name of pharisees, or separatists.

PHARMACY, the art or science which teaches the election, preparation, and mixture of medicines; constituting one part of the therapeutic branch of medicine, the objects of which are all natural bodies.

PHARNACEUM, in botany, a genus of plants, whose flower hath no corolla, but the cup resembles one, being coloured on the inside and its edges thin; it is cut into five ovate concave segments, which are equal and persistent: the stamina are five subulated filaments, the length of the cup, and topped with antheræ, which are bifid at their base: the fruit is an ovate, obscurely three-cornered, having three cells and three valves, containing a great number of depressed, orbicular, shining seeds, surrounded with a margin.

PHARYNX, in anatomy, the upper part of the œsophagus. See the article CÆSOPHAGUS.

PHASEOLUS, the kidney or French bean, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is cordated, obtuse, emarginated, and reclined, with reflexed sides; the alæ are ovate, the same length as the vexillum, and stand upon long unguis; the carina is narrow, and revolves spirally, in a contrary direction to the sun; the filaments are ten in number, nine of which are carinated and spiral, and topped with simple antheræ: the fruit is a long, straight, coriaceous legumen, ending in an obtuse point, containing oblong, compressed, kidney-shaped seeds.

There are several kinds of kidney-beans cultivated for culinary purposes; as the liver-coloured bean, the Battersea-bean, the Canterbury dwarf-bean, the speckled dwarf-bean, and those which require support; such are the white and scarlet bloomed beans, &c.

French-beans are propagated from the seeds, and are generally planted in rows, at about three inches asunder, and about an inch deep, excepting the larger sorts, which should have a greater distance. The first season for sowing them is about the latter end of April, and the last in July; but there should be intermediate sowings in May and June, to continue the supply of the table, as they will not last above three weeks in gathering, particularly in hot dry weather.

The use of kidney-beans (or rather the pods) as a food, is so well known, as to be quite unnecessary to mention it; they are opening, emollient, resolvent, and promote urine, and they generally agree with most constitutions; the meal of the seed is sometimes mixed in emollient cataplasms.

PHASES, *φασίς*, in astronomy, the several appearances or quantities of illumination of the moon, Venus, Mercury, and the other planets; or the several manners wherein they appear illuminated by the

the sun. See the articles MOON, VENUS, MERCURY, &c.

PHASMATA, in physiology, certain appearances arising from the various tinctures of the clouds, by the rays of the heavenly luminaries, especially the sun and moon. These are infinitely diversified by the different figures and situation of the clouds, and the appulses of the rays of light.

PHEASANT, *Phasianus*, in ornithology, a genus of birds of the order of the gallinæ, with the space about the eyes naked.

PHEASANT'S-EYE, *Adonis*, in botany. See the article ADONIS.

PELLANDRIUM, in botany, a genus of umbelliferous plants, the general corolla of which is almost uniform, and the proper flowers are unequal, and composed each of five acuminate, heart-shaped, inflexed petals, with five capillary filaments, topped with roundish antheræ: the fruit is naked, smooth, and crowned with the perianthium and two pifills, divisible into two parts, which form two ovate smooth seeds.

PHEONS, in heraldry, the barbed heads of darts, arrows, or other weapons.

PHILADELPHUS, *Syringa*, or mock-orange, in botany, a shrub, having a flexible creeping root, from which arise several upright stems and branches, covered with an ash-coloured bark, with a white spongy pith; the leaves are oblong, large, pointed, veiny, a little wrinkled, crenated on their edges, with their surface rough, and having the taste of a fresh cucumber: the flowers grow in loose bunches at the tops of the branches, each standing on a short peduncle; they are each composed of four white petals, which spread open, with a great number of stamina surrounding the style: the flowers have a strong scent, which, at some distance, resembles the perfume of orange-flowers, but when near, the smell is too powerful for many persons. It blows in May and June, but is seldom succeeded by seeds in this country.

This shrub rises to the height of seven or eight feet, and is easily propagated by taking off the suckers in autumn, which may be planted in a nursery for two or three years, after which they may be transplanted where it is intended they should remain, which is commonly in wildernesses, among other shrubs of the same growth.

PHILIPPICS, *φιλιππικοι λογοι*, in literature, a name given to the orations of Demosthenes against Philip king of Macedon; being esteemed the master-pieces of that great orator.

Philippic is also a term applied to the fourteen orations of Cicero against Mark Antony.

PHILIPPINES, a religious society of young women, at Rome; so called from their taking St. Philip de Neri for their protector.

They consist of a hundred poor girls, who are brought up till they are of age to be married, or

become nuns, under the direction of some religious women, who teach them to read, write, and work, and instruct them in the duties of Christianity.

They wear a white veil, and a black cross on their breasts.

PHILLYREA, mock-privet, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; it has scarce any tube, but the limb is divided into four revolute acute segments: it hath two stamina, and the fruit is a globose unilocular berry, inclosing one large round seed.

Phillyrea is an evergreen-shrub, and propagated either from seeds or layers, in autumn.

The leaves and bark of this shrub are said to be astringent, and good in ulcers of the mouth; but they are little regarded in the present practice.

PHILOLOGY, *φιλολογια*, a science, or rather an assemblage of several sciences, consisting of grammar, rhetoric, poetry, antiquities, history, and criticism.

PHILOMATHES, a lover of learning or science.

PHILONIUM, in pharmacy, a kind of somniferous anodyne opiate, taking its name from Philo, the inventor.

PHILOSOPHER, *φιλοσοφος*, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature and morality. See the article PHILOSOPHY.

PHILOSOPHIC, or PHILOSOPHICAL, something that relates to philosophy. See the articles PHILOSOPHY and PHILOSOPHER.

PHILOSOPHICAL-EGG, among chemists, a thin glass body, or bubble, of the shape of an egg, with a long neck or stem, used in digestions.

PHILOSOPHY, *φιλοσοφια*, the knowledge or study of nature and morality, founded on reason and experience.

Philosophy, among the ancients, was used in various senses: for, 1. It sometimes was used for universal knowledge, viz. of all things human and divine. 2. In a stricter notion, for the contemplation of nature only; and in this sense, a philosopher was called, by Plato, *φιλος της φύσεως*, i. e. a friend and lover of nature. 3. Sometimes for ethics, or the doctrine of manners, which we call moral philosophy. 4. It included also the mathematical arts and discipline, especially arithmetic and geometry. 5. The doctrine of existence, or *being* in the abstract, called metaphysics. 6. For the knowledge *της πρωτης καινης*, i. e. of the prime or chief good, viz. God; and this was their *prima philosophia*, or theology. 7. It was sometimes applied to logics or dialectics, which gave rules for reasoning about the nature of things.

Philosophy may be divided into three parts, intellectual, moral, and physical. The intellectual part comprizes logics and metaphysics; the moral part contains the laws of nature and nations; and, lastly,

lastly, the physical part comprehends the doctrine of bodies animate or inanimate. These, with their various subdivisions, will take in the whole of philosophy. See LOGICS, METAPHYSICS, ETHICS, POLITICS, &c.

Wolfius makes the three parts of philosophy to be the doctrine of God, the human soul, and of bodies: however, when he subdivides, and comes to treat of the several branches separately, his divisions readily come under the three heads intellectual, moral, and physical, before-mentioned.

For the method of philosophizing, or the rules for that purpose, as established by Sir Isaac Newton, See the article EXPERIMENTAL PHILOSOPHY.

PHIMOSIS, in medicine, a disorder of the penis, in which the prepuce is rendered so strict or tense, that it cannot be drawn back over the glands.

PHLEBOTOMY, in surgery, the opening a vein with a proper sharp-edged and pointed instrument of steel, in order to let out a proper quantity of blood, either for the preservation or recovery of a person's health. See the article DISEASE.

PHLEGM, *φλέγμα*, in the animal œconomy, one of the four humours whereof the ancients supposed the blood to be composed. See the article BLOOD.

The chemists make phlegm, or water, to consist of an elementary body, the characters of which are fluidity, insipidity, and volatility: and yet quicksilver has all these, which nobody pretends to be phlegm. See the article WATER.

PHLEGMAGOGUES, in pharmacy, such medicines as purge off phlegm: such are hermodactils, agaric, turbith, jalap, &c. See the article HYDRAGOGUES.

PHLEGMATIC, among physicians, an appellation given to that temperament, or habit of body, wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c. See the articles CATARRH and COUGH.

PHLEGMON, in surgery, denotes an external inflammation and tumour, attended with a burning heat, &c. See the article INFLAMMATION.

PHLEUM, in botany, a genus of plants, the corolla of which consists of two valves; and the seed, which is single, is included within the calyx and corolla.

PHLOMIS, Jerusalem sage, in botany, a genus of plants, whose flower is monopetalous and labiated; the tube is oblong; the upper lip is ovate, compressed, forked, and incumbent; the under is trifid; the middle segment is large, bilobate, and obtuse: it hath four triquetrous seeds placed in the bottom of the cup.

The leaves of this plant are accounted astringent and vulnerary.

PHLOX, bastard lichen, in botany, a genus of plants, whose flower is monopetalous and saucer-shaped; the tube is cylindraceous and longer than

the cup, it is narrow at the base and incurved; the limb is plane, and divided into five roundish, equal, obtuse segments, shorter than the tube: the fruit is an ovate trigonal capsule, having three cells, each containing an oval seed.

This genus is the same with the *lychnidea* of Dillenius.

PHŒNIX, in astronomy, one of the constellations of the southern hemisphere, unknown to the ancients, and invisible in our northern parts: it is said to consist of thirteen stars.

It took its name from that of a famous bird among the ancients, but generally looked upon by the moderns as fabulous.

The ancients speak of this bird as single, or the only one of its kind: they describe it as of the size of an eagle; its head finely crested with a beautiful plumage, its neck covered with feathers of a gold colour, and the rest of its body purple, only the tail white, and the eyes sparkling like stars; they hold, that it lives five or six hundred years in the wilderness; that, when thus advanced in age, it builds itself a pile of sweet wood and aromatic gums, and fires it with waisting of its wings, and thus burns itself; and that from its ashes arises a worm, which in time grows up to be a phœnix.

PHŒNIX, the great-palm, or date, in botany, a tree which rises to a great height; the stalks are generally full of rugged knots, which are the vestiges of the decayed leaves; the trunk is not solid, the center being filled with pith, round which is a tough bark, full of strong fibres while young, but as the tree grows old, this bark hardens and becomes ligneous; to this bark the leaves are closely joined, which in the center rise erect, being closely folded or plaited together; but after they have advanced above the vagina, which surrounds them, they expand very wide on every side of the stem, and as the older leaves decay, the stalk advances in height: the leaves, when grown to a size for bearing fruit, are six or eight feet long, and may be termed branches, for the trees have no other; these have narrow long leaves, or pinnæ, set on alternately their whole length; the small leaves, or lobes, are, toward the base, three feet long, and little more than an inch broad; they are closely folded together when they first appear, and are wrapped round with brown fibres, or threads, which fall off as the leaves advance, making way for them to expand; these never open flat, but are hollow like the keel of a boat, with a sharp ridge on their outside; they are very stiff, and when young, of a bright green, ending with a sharp black spine.

These trees have male flowers on different plants from those which produce the fruit; and there is a necessity for some of the male trees to grow near the female ones, to render them fruitful, or at least to impregnate the ovary of the seed, without which, the stones which are taken out of the fruit will not grow.

grow. Most of the old authors who have mentioned this trees, affirm, that unless the female, or fruit-bearing palm-trees, have the assistance of the male, they are barren; therefore, in such places where there are no male trees near the female, the inhabitants cut off the bunches of male flowers, when they are just opened, and carry them to the female trees, placing them on the branches near the female flowers to impregnate them, which they all agree has the desired effect, rendering the trees fruitful which would otherwise have been barren.

Labat, in his account of America, mentions a single tree of this kind growing near a convent, in Martinico, which produced a great quantity of fruit, that came to maturity enough for eating; but as there was no other tree of this kind in the island, they were desirous of propagating it, and accordingly planted great numbers of the stones, for several years, but not one of them grew; therefore, after having made several trials without success, they were obliged to send to Africa, where these plants grew in plenty, for some of the fruit; the stones of which they planted, and raised many plants. He then conjectures, that the single tree, before-mentioned, might be probably so far impregnated by some neighbouring palm-tree of other species, as to render it capable of ripening the fruit, but not sufficient to make the seeds prolific.

The flowers of both sexes come out in very long bunches from the trunk, between the leaves, and are covered with a spathe, or sheath, which opens and withers; those of the male have six short filaments, with narrow four-cornered antheræ, filled with farina; the female flowers have no stamina, but have a roundish germen, which afterwards becomes an oval berry, with a thick pulp, inclosing a hard oblong stone, with a deep furrow, running longitudinally.

These plants grow in great plenty in Africa, also in Arabia, Syria, Persia, and Greece. The dates, or fruit of the palm, are distinguished according to their degrees of ripeness; those are best which are large, full, fat, and of a yellowish colour: they are somewhat astringent until thoroughly ripe, and are then much of the same nature as figs.

They are said to be good in hoarseness, infarctions of the lungs, and sandy obstructions of the reins and bladder; they strengthen the stomach, stop loosenesses, and corroborate the intestines: they are also good in diseases of the breast; and the stones are reckoned very diuretic, and good in strangueries. Outwardly, dates are used sometimes in suppurative cataplasms.

PHOLAS, a shell-fish of the multivalve kind, composed of five pieces, three of which are very small, so that they seem, to a superficial observer, to be made up of only two shells.

PHOLIS, in natural history, a name given to the gypsums of a bright appearance.

PHONICS, *φωνικη*, the doctrine or science of sounds, otherwise called acoustics. See the article SOUND.

PHOSPHORUS, in physiology, a denomination given to all bodies which shine and seem to burn, without having any degree of heat.

Chemistry, says Dr. Shaw, hath scarce afforded any thing more surprising than the common phosphorus. To see letters traced with this matter become luminous in the dark, images and the bodies of men to blaze with light, and abundance of the like experiments, performed by means of phosphorus, must awaken the curiosity of those who have seen these experiments, and render them desirous of being acquainted with the method of preparing it. The preparation, even to this day, is kept as a secret in few hands, and the matter sold at a very high price. Whence we apprehend, it would be no unacceptable present to the world, to render this commodity cheaper, and discover its farther uses.

The successful method of preparing the phosphorus of urine, is this: evaporate any quantity of fresh urine over a gentle fire, to a black and almost dry substance; then, with two pounds thereof, thoroughly mix twice its weight of fine sand; put this mixture into a strong-coated stone long-neck; and having poured a quart or two of clear water into a large receiver, join it to the long-neck, and work it in a naked fire: let the heat be small for the first two hours; then increase it gradually to the utmost violence; and continue this for three or four hours successively: at the expiration of which time, there will pass into the receiver a little phlegm and volatile salt, much black and foetid oil, and, lastly, the matter of phosphorus, in form of white clouds, which either stick to the sides of the receiver, like a fine yellow skin, or fall to the bottom in form of small sand. Now let the fire go out, but let the receiver continue till all be cold, lest the phosphorus take fire on admission of the air.

To reduce these small grains into one piece, put them into a little tin ingot-mould, with water; heat the ingot to make the grains melt together; then add cold water, till the matter is congealed into one solid stick, like bees-wax; which being cut into small pieces fit to enter the mouth of a vial, may be preserved by water, and keeping the glass close stopped. If the glass were not to be stopped, the phosphorus would turn black on its surface, and at length be spoiled.

PHOTINIANS, a sect of Christians in the fourth century, so called from Photinus, their chief, who was bishop of Sirmich, and maintained that Jesus Christ was true man, but not true God, nor born before all ages; and that he only began to be Christ when the Holy Ghost descended upon him in the river Jordan. These doctrines were condemned in several assemblies, and particularly by the Arians, in a synod held at Sirmich in the year 351.

## P H T

**PHRASE**, *φρασις*, in grammar, a manner of speech peculiarly adapted to certain occasions, arts, languages, &c.

Sometimes the term phrase is used for a short sentence. See **SENTENCE**.

**PHRASEOLOGY**, in matters of literature, a collection of the phrases, and elegant expressions, in any language.

**PHRENETIC VESSELS**, in anatomy, the nerves, arteries, and veins which are spread over the diaphragm. The phrenetic nerves arise from the cervical ones; the phrenetic arteries arise out of the descending aorta, and are distributed through the diaphragm and pericardium; and the two phrenetic veins discharge their contents into the vena cava.

**PHRENSY**, *φρενις*, in medicine, an inflammation of the membranes of the brain, attended with an acute fever and delirium.

This disease, says Arbuthnot, requires the speediest applications of all others; profuse hæmorrhages of the nose often resolve it; and copious bleeding in the temporal arteries, is the most efficacious remedy. The diet should be water-gruel, acidulated; and the drink barley-water, small-beer, or the decoction of tamarinds.

According to Boerhaave, varices of the veins, or the bleeding piles, are beneficial; a looseness is likewise good; and a violent cough, or hæmorrhage, often put an end to the disease. He therefore advises plentiful bleeding, through a large orifice, or to open several veins at the same time, as the jugular, frontal, and a vein in the foot.

**PHRYMA**, in botany, a genus of plants, producing monopetalous ringent flowers; the tube of the corolla is the same length with the cup; the upper lip is short, ovate, and emarginated, and the under one is large, patent, and trifid; there is no pericarpium, but the cup, which is furrowed and connivent, contains a single oblong seed, furrowed on one side.

**PHTHIRIASIS**, *φθειρισις*, in medicine, the pedicularis morbus, or lousy disease, is most incident to children, though adults are not wholly exempt from it.

Cleanness and wholesome food are best for preventing this disorder, which may be cured by washing the body with a lixivium of wormwood, staves-acre, lesser centaury, and oak-ashes; adding some common salt. All the bitters, four and salt things, are here recommended; as is also mercury, which infallibly destroys these vermin; but it ought to be used with great caution, even by adults, and should never be used in applications to children.

Etmuller advises the head to be washed with a lixivium, in which has been boiled the seeds of staves-acre, and afterwards anointed with a liniment made of two drams of oil of spike, half an ounce of the oil of bitter almonds, and six drams of the oil of tobacco, which will destroy those animals in one

## P H Y

night's time. The powder of Indian berries, sprinkled on the head, also effectually destroys them. Black soap is an infallible remedy for destroying crab-lice lodged in the groins of adults.

**PHTHISIS**, *φθισις*, a species of consumption, arising from an ulcer of the lungs. See the article **CONSUMPTION**.

**PHYGETHLON**, in surgery, a broad, but not much elevated tumour, of the same nature with the bubo. See the article **BUBO**.

**PHYLACTERY**, in antiquity, a charm, or amulet, which being worn, was supposed to preserve people from certain evils, diseases, and dangers. See the article **AMULET**.

The Jews were remarkable for wearing phylacteries of parchment, in the form of slips or rolls, wherein were written certain passages of the law: these they wore upon their foreheads, and upon the wrists of their left arms. The modern Jews think themselves under no obligation to this practice, which they observe only at morning prayers.

**PHYLICA**, in botany, a genus of plants, whose flowers are collected in a disc; the proper ones are composed of five acuminate squamulae, with five small stamina. The fruit is a roundish trilobate capsule, having three cells, each containing a roundish solitary seed, gibbous on one side, and angular on the other.

**PHYLLANTHUS**, in botany, a genus of plants, producing male and female flowers, which have no petals; the cup is monophyllus, bell-shaped, and divided into six segments, and contains in the male flower three filaments, which join at the base, spreading asunder at the top, and terminated with twin antherae; the female flower has an angular nectarium surrounding the germen. The fruit is a roundish three-furrowed capsule, with three cells, each containing a single roundish seed.

**PHYLLIS**, in botany, a plant which rises with a soft shrubby stalk about two or three feet high, of an herbaceous colour, and full of joints, sending out several small side branches towards the top; these are furnished with spear-shaped leaves, of a lucid green on their upper side, but pale underneath; they have no foot-stalk, but sit close to the branches by threes. The flowers are produced at the end of the branches in loose panicles; they are small, and of an herbaceous colour, and cut into five parts to their base, and reflexed. The fruit is of a turbinate, obtuse, angular figure, which splits in two parts when ripe, each containing one seed, flat on the inside, and convex and angular on the outside. It flowers in June, and the seeds ripen in autumn.

This plant is the bupleuroides of Boerhaave, and the valerianella of Dillenius.

**PHYLLONA**, in botany, a genus of mosses, consisting only of a thin membranaceous matter, resembling in some degree a leaf; whence the name. See the article **MOSS**.

**PHYSIC**, *φυσική*, the same with medicine. See **MEDICINE**.

**PHYSIC-NUT**, in botany. See the articles **JATROPHA** and **CROTON**.

**PHYSICAL**, something relating to nature. See the articles **NATURE** and **NATURAL PHILOSOPHY**.

**PHYSICIAN**, a person who professes medicine, or the art of healing diseases.

**PHYSICS**, a denomination sometimes given to natural philosophy. See the article **NATURAL PHILOSOPHY**.

**PHYSIOGNOMONICS**, among physicians, denotes such signs as being taken from the countenance, serve to indicate the state, disposition, &c. both of the body and mind: and hence the art of reducing these signs to practice is termed *physiognomy*, than which nothing can be more precarious, in so far as it respects the characters of people, accustomed by education and practice to dissemble their sentiments.

**PHYSIOLOGY**, properly denotes a discourse of nature, and natural bodies; or, it is that part of natural philosophy which treats of the various phenomena of nature in a scientific and speculative way; in which sense, neither chemistry nor experimental philosophy are included under it. However, as experiments ought always to precede any reasonings concerning the natures and properties of natural bodies, we have given the rules to be observed in drawing conclusions from them under the article **EXPERIMENTAL PHILOSOPHY**.

If we take a view of the several phenomena, and compare them together, we may observe some likeness and conformity between them. For example, in the falling of a stone to the ground, in the rising of the sea towards the moon, in cohesion and crystallization, there is something alike; namely, an union or mutual approach of bodies: so that any one of these, or the like phenomena, may not seem strange or surprising to a man who has nicely observed and compared the effects of nature: for that only is thought so which is uncommon, or a thing by itself, and out of the ordinary course of our observation. That bodies should tend towards the center of the earth is not thought strange, because it is what we perceive every moment of our lives; but that they should have a like gravitation towards the center of the moon, may seem odd and unaccountable to most men, because it is discerned only in the tides; but as a philosopher, whose thoughts take in a larger compass of nature, having observed a certain similitude of appearances, as well in the heavens as the earth, that argue innumerable bodies to have a mutual tendency towards each other, which he denotes by the general name attraction, whatever can be reduced to that, he thinks justly accounted for; and thus he explains the tides by at-

traction. See the articles **ATTRACTION** and **TIDE**.

If therefore we consider the difference there is betwixt natural philosophers and other men, with regard to their knowledge of the phenomena, we shall find it consists only in a greater largeness of comprehension; whereby analogies, harmonies, and agreements are discovered in the works of nature, and the particular effects explained; that is, reduced to general rules, which rules, grounded on the analogy and uniformness observed in the production of natural effects, are most agreeable and sought after by the mind; for that, they extend our prospect beyond what is present and near to us, and enable us to make very probable conjectures touching things that may have happened at very great distances of time and place, as well as to predict things to come; which sort of endeavour towards omniscience, is much affected by the mind.

Among physicians, the term *physiology* denotes the history of the human body and its several constituent parts, with their relations and functions.

**PHYTEUMA**, in botany, a genus of plants whose flower is monopetalous and stellated, with five filaments topped with oblong antheræ. The fruit is a roundish trilocular capsule, containing many roundish small seeds.

**PHYTOLACCA**, American nightshade, in botany, a genus of decandrious plants, whose flower consists of five roundish, concave, spreading, persistent petals: the fruit is an orbiculated depressed berry, with ten longitudinal furrows, and the same number of cells, each containing a smooth kidney-shaped seed. It is very common in our North-American plantations; and is cultivated in England for the beauty of its flowers: it may be propagated by sowing the seeds in the spring upon a bed of light rich earth, and when the plants are come up, they should be moved into the borders of large gardens, allowing them room enough to grow, for they become very large. The planters take a spoonful or two of the juice of the root as a purge, and that very frequently. The berries are full of a purple juice, which gives a fine tincture to paper, but will not last long, if there could be a method of fixing the dye, it might be made very useful.

**PHYTOLOGY**, a discourse concerning the kinds and virtues of plants.

**PIA MATER**, in anatomy, the third tunic or membrane of the brain, placed immediately under the tunica arachnoides, and closely and firmly connected to the brain: it not only extends over the whole surface of the brain, but insinuates itself into all its cavities, and is carried down to the bottom of all its furrows. It covers also the spinal marrow, and all the nerves, and adheres also to the tunica arachnoides very closely and firmly, in the upper part of the head; but much less so below, with the dura mater.

**PIASTER**, a Spanish coin, more ordinarily called a piece of eight.

**PICA**, in zoology, the largest animal of the mus, or mouse-kind, being as big as a pig of a week old: it is of a brown colour spotted with grey, and with a white belly; the upper lip is divided, and a little longer than the under one; the ears are short, and obtuse; the body is thick and fleshy, and the legs short, especially the fore ones.

**PICA**, in medicine, a depravation of appetite, which makes the patient long for what is unfit for food, or incapable of nourishing, as chalk, ashes, coals, plaster, lime, &c.

**PICARDS**, a sect so called from their leader, one Picard, a Fleming, who, about the beginning of the fifteenth century, improved upon the error of the Adamites, in respect to nakedness; and who pretended that he was sent into the world, as another Adam, to restore the law of nature, which, he said, consisted principally of two things, a community of women, and a nakedness of all the parts of the body.

**PICKAGE**, or **PICCAGE**, an antient custom or duty paid at fairs and markets, for breaking the ground, and pitching up stalls or standings.

**PICKLE**, a brine or liquor, commonly composed of salt, vinegar, &c. sometimes with the addition of spices, wherein meat, fruit, and other things are preserved and seasoned. The same name is also given to any vegetable production prepared in pickle.

The methods of pickling the various sorts of vegetables, and even those of the same kind, are very different: we shall therefore content ourselves with giving one out of the numerous methods of pickling walnuts: Take walnuts before the shell is grown hard, scald them, and rub off the outer skin; then put them into water and salt for nine or ten days, shifting them every other day, and keeping them close covered from the air; then dry them, and prepare the pickle as follows: for half a hundred of large walnuts, take two quarts of white-wine vinegar; long pepper, black-pepper, and ginger, of each half an ounce; cloves, mace, and nutmegs, of each a quarter of an ounce: pound the spice, and with it a spoonful of mustard-seed; strew this between every layer of walnuts, pour the liquor boiling hot upon them, and keep them close stopp'd.

**PIQUEERING**, **PICKEERING**, or **PICKE-ROONING**, a flying war or skirmish made by soldiers detached from two armies by pillage, or before a main battle begins.

**PICQUET**, a celebrated game at cards played between two persons, with only thirty-two cards; all the ducies, threes, fours, fives and sixes being set aside.

**PICRIS**, in botany, a genus of plants, whose

flower consists of a double cup, with a compound imbricated, uniform corolla; the proper flowers are hermaphrodite, monopetalous, ligulated, linear, truncated, and quinque-dentated; there is no pericarpium, but the seeds, which are solitary, sentricose, obtuse, and crowned with down, are contained in the cup. This genus comprehends the *helminthotheca* of Vaillant.

**PICTS-WALL**, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England; to prevent the incursions of the Picts and Scots. It was first made only of turf, strengthened with palisadoes, till the emperor Severus coming in person into Britain, built it with solid stone. This wall, part of which still remains, begun at the entrance of Solway-frith in Cumberland, and running N. E. extended to the German ocean.

**PICTURE**, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like.

**PIECE**, in commerce, signifies sometimes a whole, and sometimes a part of the whole. In the first sense, we say a piece of cloth or velvet, &c. meaning a certain quantity of yards regulated by custom; being yet intire, and not cut. In the other signification we say a piece of tapestry; meaning a distinct member wrought apart, which, with several others, make one hanging.

**PIECE**, in matters of money, signifies sometimes the same thing with species; and sometimes by adding the value of the pieces, it is used to express such as have no other particular name.

**PIECE** is also a kind of money of account, or rather a manner of accounting used among the negroes on the coast of Angola in Africa. See the article **MONEY**.

**PIECE**, in heraldry, denotes an ordinary or charge. See the article **ORDINARY**.

**PIECES**, in the military art, include all sorts of great guns and mortars. Battering pieces are the larger sort of guns used at sieges for making the breaches, such as the twenty-four pounder, and culverine, the one carrying twenty-four, and the other an eighteen pound ball. Field-pieces are twelve-pounders; demiculverines, six-pounders, sakers, minions, and three-pounders, which march with the army, and encamp always behind the second line, but in the day of battle are in the front. A soldier's firelock is likewise called his piece.

**PIEDOUCHE**, in architecture, a little stand or pedestal, either oblong or square, enriched with mouldings, serving to support a bust, or other little figure.

**PIEDROIT**, in architecture, a pier, or square kind of pillar, part whereof is hid within a wall. The only thing wherein it differs from a pilaster is, that the latter has a regular base and capital, which the other wants. See **PILASTER**.

This term is also used for part of the solid wall annexed to a door or window, comprehending the door-post, chambranel, tableau, leaf, &c.

**PIEPOWDER-COURT**, or **PEDES PULVERISATI**, a court held in fairs for doing justice to buyers and sellers, and redressing disorders there committed.

**PIER**, or **PEER**, in building, denotes a mass of stone, &c. opposed by way of fortress against the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

It is also used in architecture for a kind of pilaster, or buttress, raised for support, strength, and sometimes for ornament.

**PIERCEA**, in botany, see the article **REVINIA**.

**PIERCED**, **PERCE**, in heraldry, is when any ordinary is perforated, or struck through, shewing, as it were, a hole in it, which must be expressed in blazon, as to its shape: thus if a cross have a square hole, or perforation in the centre, it is blazoned square-pierced, which is more proper than quarterly-pierced, as Leigh expresses it. When the hole or perforation is round, it must be expressed round-pierced; if it be in the shape of a lozenge, it is expressed pierced lozenge-ways. All piercings must be of the colour of the field, and when such figures appear on the centre of a cross, &c. of another colour, the cross is not to be supposed pierced, but the figure on it is a charge, and must be accordingly blazoned.

**PIETISTS**, a religious sect sprung up among the protestants of Germany, seeming to be a kind of mean between the quakers of England, and the quietists of the Romish church. See the article **QUAKERS**, &c.

They despise all sorts of ecclesiastical polity, all school theology, and all forms and ceremonies, and give themselves up to contemplation and the mystic theology.

**PIG**, in zoology, the young of the hog kind. See the article **HOG**.

**PIG of Lead**, the eighth part of a fother, amounting to two hundred and fifty pounds weight.

**PIGEON**, in ornithology. See the article **CO-LUMBA**.

**PIGEON-HOUSE**, a house erected full of holes within for the keeping, breeding, &c. of pigeons, otherwise called a dove-cote.

**PIGMENTS**, *Pigmenta*, preparations used by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours.

**PIGMY**, or **PYGMY**. See **PYGMY**.

**PIKE**, an offensive weapon, consisting of a shaft of wood, twelve or fourteen feet long, headed with a flat-pointed steel, called the spear. The pike was a long time in use among the infantry, to enable them to sustain the attack of the cavalry, but it is now taken from them, and the bayonet, which fixes

on at the end of the carabine, is substituted in its place. Yet the pike still continues the weapon of foot-officers, who fight pike in hand, salute with the pike, &c.

**PILASTER**, in architecture, a square column, sometimes insulated, but more frequently let within a wall, and only shewing a fourth or fifth part of its thickness.

The pilaster is different in different orders: it borrows the name of each, and has the same proportions, and the same capitals, members and ornaments with the columns themselves. Pilasters are, however, usually made without either swelling or diminution, and as broad at top as at the bottom; though some of the modern architects, as M. Mansard, &c. diminish them at the top, and even make them swell in the middle, like columns, particularly when placed behind columns.

**PILE**, in antiquity, a pyramid built of wood, on which the bodies of the deceased were laid in order to be burned.

**PILE**, in building, is used for a large stake rammed into the ground in the bottom of rivers, or in marshy land, for a foundation to built upon.

Pile is also used among architects for a mass of building.

**PILE**, in coinage, denotes a kind of puncheon, which, in the old way of coining with the hammer, contained the arms, or other figure, and inscription, to be struck on the coin.

Accordingly, we still call the arms-side of a piece of money, the pile; and the head, the cross; because, in ancient coins, the cross generally took the place of the head in ours: but some will have it called pile, from the impression of a ship built on piles, struck on this side our ancient coins.

**PILE**, in heraldry, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the shield.

**PILES**, in medicine, the same with hæmorrhoids. See the article **HÆMORRHOIDS**.

**PILGRIMAGE**, a kind of religious discipline, which consists in taking a journey to some holy place, in order to adore the relics of some deceased saint.

Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the eleventh century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account.

The places most visited were Jerusalem, Rome, Compostella, and Tours; but the greatest numbers now resort to Loretto, in order to visit the chamber of the Blessed Virgin, in which she was born, and brought up her son Jesus, till he was twelve years of age.

# P I L

This chamber, it is pretended, was carried by angels into Dalmatia, about the year 1291, and afterwards, in the same manner, transported to Loretto, where a magnificent cathedral is built over it. In this chamber is the image of the Blessed Virgin, almost covered with pearls and diamonds; and round the statue, is a kind of rainbow formed of precious stones of various colours. Five hundred thousand pilgrims sometimes resort to this house in one year, in order to pay their devotions before this glorious image.

The Mahometans are commanded in the Koran, to perform a pilgrimage to Mecca; this is one of the capital points of their religion, and therefore a prodigious cavalcade of pilgrims annually go thither, in the company of those who are sent with the grand seignor's presents, to the tomb of Mahomet.

**PILL**, in pharmacy, a form of medicine resembling a little ball, to be swallowed whole, invented in favour of such as cannot take bitter and ill-tasted medicinal draughts, as also to keep in readiness for occasional use without decaying.

**PILLAGE**, among builders, is a square pillar, standing behind a column, to bear up arches.

**PILLAR**, in architecture, a kind of irregular column, round and insulated, but deviating from the proportions of a just column.

Pillars are always either too massive, or too slender for regular architecture; such are the pillars that support Gothic vaults, or buildings; and, indeed, they are not restrained by any rules, their parts and proportions being arbitrary.

*Butting-PILLAR*, the same with a buttress. See the article **BUTTRESS**.

*Square-PILLAR*, a massive work, called also a pier, or piedroit, serving to support arches, &c.

**PILLAR**, in the manege, is the center of the ring or manege-ground, round which a horse turns, whether there be a pillar in it or not.

Besides this, there are pillars in the circumference, or sides of the manege-ground, placed at certain distances, by two and two; whence they are called the two pillars, to distinguish them from that of the center.

**PILLORY**, was anciently a post erected in a cross-road, by the lord of the manor, with his arms upon it, as a mark of his feigniory, and sometimes with a collar to fix criminals to.

At present it is a wooden machine, made to confine the head and hands, in order to expose criminals to public view, and to render them publicly infamous.

According to Sir Henry Spelman, it was at first peculiarly intended for the punishment of bakers, who should be found faulty in the weight or fineness of their bread. At present, the persons thus punished, are foresters, those using false weights, persons guilty of perjury, &c.

# P I M

**PILOT**, a person employed to conduct ships over bars and sands, or through intricate channels, into a road or harbour.

**PILULARIA**, in botany, a genus of ferns, the male fructifications of which grow in lines, like powder, under the leaf, and the female, towards the root, consisting of round polyspermous cells.

**PIMENTA**, or *Pimento*, the all-spice tree, in botany; it grows naturally in Jamaica, to the height of thirty or more feet; the trunk is strait, covered with a smooth brown bark, and divides upwards into many branches, which come out opposite, and are furnished with oblong leaves, like those of the bay tree, both in form, colour, and texture, and placed opposite; these when bruised or broken emit a fine aromatic odour; the flowers are produced in large loose bunches from the side of the branches toward their ends; the flowers are small, and of an herbaceous colour, and are male or female on distinct plants. The male flowers have very small petals, and a great number of stamina in each. The female flowers have an oval germen, supporting a slender style, crowned with a blunt stigma; the germen afterward becomes a globular, pulpy berry, with two cells each, containing a kidney-shaped seed. The unripe fruit of this tree makes a considerable branch of commerce, being the all-spice, so well known in Europe. They are gathered a little before they arrive to their full size, and are separated from the leaves, stalks, or any thing which might accidentally be mixed with them, and exposed every day to the sun, spread on cloths, for a fortnight, to dry, frequently shaking and turning them, but are removed under cover every evening, to screen them from the dews, and when thus dried, are packed up and exported.

Pimenta abounds with a fragrant essential oil, which is separated, in great quantity, in distillation, and is so heavy that it sinks in water.

This spice is much used in our foods, and sometimes in medicine: it is, indeed, a very good aromatic, and so well imitates the mixed flavour of all the rest, that it has long been a common practice to make the aqua marabilis, which was ordered to be distilled from all the spices, of this ingredient alone; and the taste of the water thus made, when carefully done, is so near the genuine, that a very nice palate can only distinguish it.

The present college-dispensatory orders a simple water to be distilled from it, a gallon from half a pound of that spice, which is a better carminative than any of the former waters retained under that name.

**PIMPERNEL**, *Anagallis*, in botany. See the article **ANAGALLIS**.

**PIMPINELLA**, burnet-saxifrage, in botany, a genus of umbelliferous plants, the principal umbel is formed of many rays; the proper flowers contain  
five

five heartshaped, inflexed petals, which are almost equal, it hath no pericarpium, but the fruit is ovate, oblong, and divided into two parts, containing two oblong furrowed seeds, convex on one side, and flat on the other. The common sort, which grows wild in many parts of England, is said to be detergent, vulnerary, and diuretic. This genus comprehends the tragofelinum of Tournefort.

**PIMPLE**, in surgery, a small pustule, arising chiefly on the face. See the article **PUSTULE**.

**PIN**, in commerce, a little necessary implement, made of brass wire, used chiefly by the women in adjusting their drefs.

**PINASTER**, in botany, a species of the pine tree. See **PINE**.

**PINDARIC**, in poetry, an ode formed in imitation of the manner of Pindar.

The Pindaric manner is distinguished by the boldness and height of the flights, the suddenness and surprisingness of the transitions, and the seeming irregularity, wildness, and enthusiasm of the whole.

The only part remaining of Pindar's works, is a Book of Odes, all in praise of the victors at the Olympian, Pythian, Nemæan, and Isthmian, games: whence the first is intitled the Olympians; the second, the Pythians; the third, the Nemæans; and the fourth, the Isthmians.

**PINE**, *Pinus*, in botany, a genus of ever-green trees, the leaves of which come out of small sheaths, in pairs in some species, and in others by threes or fives; they are of a bluish-green colour, and placed, for the most part, on every side of the branches; the flowers are male and female, growing on the same tree, and are both destitute of a corolla; the male flowers are collected in a bunch, and contain many stamina connected in a column at their base, but dividing at the top: the female flowers are collected in a common, almost oval, cone, and stand at a distance from the male on the same tree, the scales of which are biforous, oblong, imbricated, and persistent, under which a small germen is placed, supporting a subulated style, crowned with a single stigma, which becomes an oblong oval nut, crowned with a membranaceous wing, and included in the rigid scale of the cone.

There are several species of pine trees, which are raised for sale in the nurseries, but the most valuable are, what is commonly called the Scotch fir, and a North American species, known among the gardeners here, by the name of lord Weymouth's pine, the former of which grows naturally on the mountains of Scotland, also in Denmark, Norway, and Sweden, the leaves of which grow out of a sheath in pairs, which are twisted, and are of a greyish colour: it will grow on almost any soil, and the timber of it is the most durable of any kind of pines yet known, the best yellow deals being the wood of this tree.

The lord Weymouth's pine grows naturally in most parts of North America; it is one of the tallest trees of all the species, often growing to a hundred feet high in those countries; the bark is very smooth, the leaves are long and slender, five growing out of each sheath, the branches are pretty closely furnished with them, so makes a fine appearance; the cones are long, slender, and very loose, opening with the first warmth of the spring, so that if they are not gathered in the winter, the seeds will be shed: the wood of this sort is much esteemed for making masts for ships, &c. This sort, and the Scotch pine, are the best worth cultivating of all the kinds, for the sake of their valuable timber. All the sorts of pine trees are raised from the seeds taken out of their polyspermous cones: the way to get them out is, by exposing the cones to a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out, but this should not be done until the season is arrived for sowing, which is about the middle of March, and when the seeds are sown, they should be protected by nets from the birds, otherwise they will be in danger of being destroyed when they first come up, for as they bring up the husks on the top of the plants, the birds will pick off the heads of the plants, whereby they are destroyed, unless carefully guarded against. If the quantity of seeds to be sown is few, they may be raised in pots or boxes, but if large, so as to require a good space to receive them, then they may be sown on an east or north-east border, where they may be screened from the sun, and those which are sown in pots or boxes, should be placed in a shady situation, here they may remain till the spring following, when they should be transplanted into the nursery, at the distance of six or eight inches asunder, where they may remain two years, and afterward transplanted, where they are to continue for good.

The Scotch pine being the hardiest of all the kinds, and the wood of it the most useful (as was before observed) is the sort which best deserves our notice; this will thrive upon the most barren sands, where scarce any other plants will grow, except heath and furze; and as there are many thousand acres of such land, lying convenient for water-carriage, in this kingdom (and is at present of little use to any one) it might be so improved by plantations of these trees, as to become good estates to the proprietors of such lands, and also a national benefit; and, as the legislature has taken this into consideration, and have already passed some laws for the encouragement of these plantations, and also for their preservation and security; so it may be hoped, that this will be undertaken by the gentlemen who are possessed of such lands, in all the different parts of this kingdom, with proper spirit; for although they may not expect to receive much profit from these plantations in their own time, yet their successors may,

may, with large interest: and the pleasure which these growing trees will afford them, by beautifying the present dreary parts of the country, will, in some measure, recompence them for their trouble and expence.

To this genus Linnæus has added the fir and larch trees; which see. From the wild pine or pineaster is procured the common turpentine; and the kernels of the nuts of the manured or stone-pine are of a balsamic nourishing nature, and good for consumptions, coughs, and hoarseness; they are restorative, and of service after long illness.

PINE-APPLE, *Ananas*, in botany. See the article ANANAS.

Ground-PINE, in botany. See the article CHAMÆPITYS.

PINEAL GLAND, in anatomy, a gland in the third ventricle of the brain; thus called from its resemblance to a pine-apple.

It is of a greyish colour, and its process and base are often medullary: this gland has often by many been supposed the peculiar seat of the soul.

PINGUICULA, butter-wort, in botany, a genus of plants, whose flower is monopetalous and ringent, the longer lip of which is straight, obtuse, trifid and supine; the shorter lip is bifid, more obtuse, and spreading: it hath a corniculated nectarium, produced from the base of the petal: the stamina are two cylindric curved filaments, topped with roundish antheræ; and the fruit is an ovate capsule, compressed at the top, having one cell, which contains many cylindraceous seeds, with a loose receptacle.

This genus grows wild in boggy lands in divers parts of England.

PINION, in mechanics, an arbor, or spindle, in the body whereof are several notches, that catch the teeth of a wheel that serves to turn it round: or it is a lesser wheel which plays in the teeth of a larger.

In a watch, &c. the notches of a pinion, which are commonly 4, 5, 6, 8, &c. are called leaves, and not teeth, as in other wheels.

PINK, in botany, the English name for several beautiful species of dianthus, much cultivated in our gardens; the principal of which are, the pheasant's-eye pink, with double and single flowers; the common red pink, the cob pink, Dobson's pink, white cob pink, the painted-lady pink, the China pink, &c. They are all propagated by slips, layers, or from seed.

The best time for planting the slips of pinks is in July or August, taking the opportunity of moist weather: the China or Indian pink is propagated from seeds, which should be sown upon a gentle hot bed about the beginning of April, and in about three weeks or a month the plants will be up, and stout enough to remove; they should then be taken up, with a ball of earth to their roots, and planted in a bed of rich mould, at about three inches asun-

der, and in dry weather must be frequently watered; the farther care is to keep them from being over-run with weeds, till June, at which time they may be transplanted to the place where they are designed to remain for flowering. If they are taken up with large balls to their roots (as before directed) they will not be injured by their removal; and as they grow not very large, it is best to plant them in beds, at about eight inches asunder, where they will make a more beautiful appearance than intermixed with other flowers, there being a fine contrast among these flowers, as scarce any two are marked alike; for no sort of plant produces such varieties of rich-coloured flowers as these do, which annually vary when raised from seeds.

As all the different kinds of pinks are either species or varieties of the dianthus (which comprehends the carnations and sweetwilliams also) we must therefore refer the reader to the article CARNATION for the generical characters of these plants.

PINNACLE, in architecture, the top or roof of a house, terminating in a point.

This kind of roof, among the ancients, was appropriated to temples; their ordinary roofs were all flat, or made in the platform way. It was from the pinnacle that the form of the pediment took its rise.

PINNATED LEAVES, *Pinnata Folia*, in botany, those which are composed of several folioles, or partial leaves, connected to the sides of a petiole, in the form of wings.

Of pinnated leaves there are several kinds, as 1. the pinnated with an odd one, that is, when it is terminated with an odd foliole; 2. the cirrhose-pinnated leaf, when it is terminated with a tendril or clasper; 3. an abrupt-pinnated leaf, when it is terminated neither by a foliole or cirrhus; 4. the oppositely-pinnated, is when the folioles, or lobes, stand opposite on the mid-rib or petiole; 5. the alternately-pinnated, when the folioles are produced alternately; 6. the interruptedly-pinnated, when the folioles are alternately less; 7. the articulately-pinnated, when the petiole, common to all the folioles, is jointed; 8. the decursively-pinnated, when the folioles run along the petiole from one to another; 9. the conjugate-pinnated, when the leaf consists but of two folioles only on the petiole; 10. Bepinnate or duplicato-pinnated, when the foot-stalk is divided, and each division sustains several folioles ranged on their sides like wings; 11. triplicato pinnate, expresses a leaf, the petioles of which send out three alated divisions, before it has any folioles on it; these last are terminated sometimes by two folioles each, and in that case are said to be abrupt, sometimes by an odd foliole, and are then called triplicato-pinnata cum impari.

PINNING, in building, the fastening of tiles together, with pins of heart of oak, for the covering of a house, &c.

PINT, a vessel, or measure, used in estimating the

# PIP

the quantity of liquids, and even sometimes of dry things. See the article MEASURE.

PINTLE, among gunners, an iron, which serves to keep the guns from recoiling.

PINUS, the pine-tree, in botany. See the article PINE.

PIONEER, in the art of war, a labourer employed in an army to smooth the roads, pass the artillery along, and dig lines and trenches, mines, and other works.

PIONY, in botany. See the article PÆONY.

PIP, or PEP, *Pepia*, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding. It usually arises from want of water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with salt. Hawks are particularly liable to this disease, especially from feeding on stinking flesh.

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other liquids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are usually made of oak or elder. Those of iron are cast in forges, their usual length is about two feet and a half; several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron-pipes. The wooden pipes are trees boared with large iron augres, of different sizes, beginning with a less, and then proceeding with a larger successively; the first being pointed, the rest being formed like spoons, increasing in diameter, from one to six inches or more.

PIPE also denotes a vessel or measure for wine, and things measured by wine-measure. See the article MEASURE.

PIPE, in mining, is where the ore runs forwards end-ways in a hole, and doth not sink downwards, or in a vein.

PIPE-TREE, in botany, a name given some-

# PIS

times to the *lyringa* or *philadelphus*. See the article PHILADELPHUS.

PIPER, pepper, in botany. See PEPPER.

PIPPS, among florists, are the distinct flowers of such plants which grow in trusses or bunches, and is particularly applied to auriculas and polyanthes.

PIQUETTES, among florists, a kind of carnations; they have always a white ground, and spotted or pounced with red, scarlet, purple, or other colours. See the article CARNATION.

PIRATE, PYRATE, or ROVER, *Pirata*, a person, or vessel, that robs on the high seas, without permission or authority of any prince or state.

When a pirate enters into any port or haven, and there robs a merchant's ship, this is not held to be piracy, because it is not done on the high sea, but it is a robbery at common law. In case a ship is riding at anchor on the sea, and it happens that the mariners or seamen are part in their boat, and the rest on shore, by which accident none are left in the ship; here, if a pirate shall attack her, and commit a robbery, the same is piracy. Nevertheless, the taking, by a ship at sea, in great necessity of victuals, cables, ropes, &c. such things out of another vessel, is not so, where that other vessel can spare such things, and the takers pay or give security for them. The manner of trying a pirate, is by a special commission, directed to the lord high admiral, &c. and the offence of piracy may be heard and determined, as if the robbery was committed on land; and offenders shall suffer the like pains of death, loss of lands and goods, &c. Persons combining to yield up ships to pirates, or to lay violent hands on the commanders of ships, or that correspond with any pirate, are adjudged guilty of piracy. All the proper goods of pirates are granted to the lord high admiral by patent; but not their piratical goods, which, where the owner is not known, belong to the king.

PISCES, in astronomy, the twelfth sign or constellation of the zodiac.

The stars in pisces, in Ptolemy's catalogue, are 38; in Tycho's, 33; in the Britannic catalogue 109. The longitudes, latitudes, magnitudes, &c. are as follow. See plate LXXIV.

**PISCIDIA**, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is emarginated and rising upwards; the alæ are of the same length as the vexillum; and the carina is moon-shaped and ascendant: the fruit is a membranaceous linear pod, having four longitudinal angles, and containing a few almost cylindrical seeds.

**PISCINA**, in antiquity, a large basin in a public place or square, where the Roman youth learned to swim, and which was surrounded with a high wall, to prevent casting of filth into it.

**PISCIS VOLANS**, in astronomy, a small constellation of the southern hemisphere, unknown to the ancients, and invisible to us in these northern regions.

**PISONIA**, in botany, a genus, producing male and female flowers on different plants; the flower of the male is funnel-shaped, the tube short, and the limb is cut into five acute segments, and spreads open; the filaments are five or six, and awl-shaped, terminated by obtuse antheræ; the female flowers are of the same form, and the fruit is an oval quinquangular capsule, or berry, having but one cell, which contains a smooth oblong seed.

**PISSASPHALTUM**, earth pitch, in natural history, a fluid, opaque, mineral body, of a thick consistence, of a strong smell, readily inflammable, but leaving a residuum of greyish ashes after burning.

It arises out of the cracks of rocks, in several places in the island of Sumatra, and in some other parts of the East-Indies, and is much esteemed there in paralytic disorders. It is greatly recommended by the ancients as an emollient, maturant, and digestive; and was used in cataplasms for ripening all sorts of tumours, and against the sciatica, and other pains of the limbs.

**PISSÆLÆUM INDICUM**, Barbadoes-tar, in natural history, a mineral fluid, of the nature of the thicker bitumens, and of all others the most approaching, in appearance, colour, and consistence, to the true pissasphaltum, though differing from it in other respects.

It is very frequent in many parts of America, where it is found trickling down the sides of mountains in large quantities, and sometimes floating on

the surface of the waters: but it seems to be almost lost at this time in the island of Barbadoes, whence it was originally named.

It has been greatly recommended internally in coughs and other disorders of the breast and lungs; but it is seldom to be met with genuine.

**PISTACIA**, in botany, a genus, producing male and female flowers on separate trees; the male flowers are disposed in a loose scattered amentum, having small unisporous scales; there is no corolla, but the perianthium, which is small and quinquefid, contains five small filaments, topped with ovate, four-cornered, large, erect antheræ; the female flower has a small trifid cup, with no corolla; the germen is ovate, larger than the cup, supporting three reflexed styles, crowned with thick prickly stigmas: the fruit is a dry ovate drupe, containing a smooth nut of the same shape.

Pistachia-nuts are brought from Persia, Arabia, Syria, and the East-Indies; in these countries, the trees which produce them, grow to the height of twenty-five or thirty feet; the bark of the stem and old branches are of a dark russet colour, but the young branches are of a light brown; these are furnished with pinnated leaves, composed sometimes, and at others, three pair of folioles, terminated by an odd one; they approach toward an oval shape, and their edges turn backwards, which emit an odour like the nuts.

These nuts abound with a sweet and well-tasted oil, which they will yield in great abundance, on being pressed after bruising them: they are reckoned wholesome and nutritive, and are very proper to be prescribed by way of restoratives, eaten in a moderate quantity, and to people emaciated with long illnesses. They are recommended as peculiarly good to prevent obstructions of the liver.

**PISTIA**, in botany, a genus of gynandrous plants, whose flower is monopetalous, lubulose, and unequal; the limb is ear-shaped, erect, and acuminate: the fruit is an ovate unilocular capsule, containing many oblong seeds, affixed to the back of the capsule.

**PISTIL**, *Pistillum*, among botanists, denotes the female organ of generation in flowers, and is defined, by Linnæus, as an entrail of the plant, designed

signed for the reception of the farina, or male-duft, wherewith it becomes impregnated; it consists of three parts, viz. the germen, style, and stigma; the germen is the rudiment of the fruit, accompanying the flower, and is of various shapes, but always situated below the style, or stigma, and contains the embryo-feeds; the style is the part that serves to elevate the stigma from the germen, and is also of different forms; the stygma, which is of various shapes likewise, is always placed on the top of the style, or, if that be wanting, on the top of the germen; this part is covered with a moisture, for the breaking of the farina into more minute parts.

The pistil, being the female part of a flower, is of great consequence in the Linnæan System of Botany. See the article BOTANY.

PISTOL, the smallest piece of fire-arms, borne at the saddle-bow, on the girdle, and in the pocket.

PISTOLE, a gold coin struck in Spain, and in several parts of Italy, Switzerland, &c.

The pistole has its augmentations and diminutions, which are, quadruple-pistoles, double-pistoles, and half-pistoles.

PISTON, *Embolus*, in pump-work, is a short cylinder of metal, or other solid substance, fitted exactly to the cavity of the barrel or body of the pump.

PISUM, the pea, in botany. See the article PEA.

PITCH, a tenacious oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various other arts: or it is more properly tar, inspissated by boiling it over a slow fire.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees.

As the substance of the trunk in trees, says Boerhaave, become more woody, the pith is compressed and strengthened to such a degree, that it wholly disappears. It is plain from this, that the office of the pith in vegetation, cannot be very great, since it is not of perpetual duration. By its spongy structure, it seems fitted to receive any superfluous moisture, that might transude through the pores of the woody fibres. If by the excess of such moisture, or from any other cause, it happens to rot and perish, as frequently happens in elms, the tree is found to grow full as well without it; a proof it is of no essential use in vegetation.

PITUITARY GLAND, in anatomy, a gland in the brain, of the size of a very large pea, placed under the cella of the os sphenoides, under the infundibulum, wherewith it communicates, receiving from it a lymph or a juice, which the infundibulum derives from the plexus choroides and pineal gland; and from this lymph does the gland itself take its name. It also filtrates a juice itself, separating from the blood a white liquor, very subtil, and apparently very spirituous.

PIVAT, or PIVOT, a foot or shoe of iron,

or other metal, usually conical, or terminating in a point, whereby a body, intended to turn round, bears on another fixed at rest, and performs its circumvolutions. The pivot usually bears or turns round in a sole, or piece of iron or brass, hollowed to receive it.

PLACARD, or PLACART, among foreigners, signifies a leaf or sheet of paper, stretched out and applied on a wall or post, containing edicts, regulations, &c.

Among us, placard signifies a licence, whereby a person is permitted to use unlawful games, &c.

PLACARD, in architecture, denotes the decoration of the door of an apartment, consisting of a chambranle, crowned with its frieze or gorge, and a corniche, sometimes supported by consoles. See the article DOOR.

PLACE, *Locus*, in philosophy, a mode of space, or that part of immoveable space which any body possesses. See the article SPACE.

Optical PLACE, the point to which the eye refers an object.

PLACE of Radiation, is the space in a medium or transparent body, through which any visible object radiates.

Excentric PLACE of a Planet. See the article EXCENTRIC.

Geocentric PLACE of a Planet. See the article GEOCENTRIC.

Heliocentric PLACE of a Planet. See the article HELIOCENTRIC.

PLACE, in geometry. See the article LOCUS.

PLACE, in war, a general name for all kinds of fortresses where a party may defend themselves.

PLACE, in logic and oratory, denotes the seat or source of an argument, of which there are two kinds, inartificial and artificial; the first is the place of testimony, authority, &c. the second, that of reason, as when we argue from universals, causes, &c.

Common PLACE. See the article COMMON PLACE.

PLACENTA, in anatomy, a soft roundish mass, found in the womb of pregnant women; which, from its resemblance to the liver, was called by the ancients, *hepar uterinum*, the uterine liver.

PLACENTA, is also a term used, by some botanists, for what is more usually called the receptacle of the seeds. See the article RECEPTACLE.

PLAFOND, or PLAFOND, in architecture, the ceiling of a room, whether it be flat or arched, lined with plaster or joiner's work, and frequently enriched with painting.

The word plafond is also more particularly used for the bottom of the projecture of the larmier of the corniche, called also *sosfit*. See the article SOSFIT.

PLAGIARY, in philology, the purloining another person's works, and putting them off for a man's own.

PLAGUE,

**PLAGUE, PESTILENCE, or PESTILENTIAL-FEVER**, a most acute fever, arising from a poisonous miasma, brought from oriental countries, which, unless it is immediately expelled out of the body, by the strength of the vital motions, by buboes and carbuncles, proves fatal.

In this, as well as in most contagious diseases, says Hoffman, the venomous miasma is swallowed with the air, and insinuates itself into the salivary juice; whence it assails the head, brain, nerves, and animal spirits; producing a torpor in the head, a heaviness, a sleepiness, a violent pain, a stupor of the senses, a forgetfulness, inquietude, watching, and loss of strength. From the fauces it proceeds to the stomach, creating a loathing of food, nausea, anxiety of the precordia, a cardialgia attended with fainting, reaching to vomit, and vomiting itself. Hence it proceeds to the membranes of the spinal marrow, the coats of the arteries, producing horrors, a languid, small, contracted, quick pulse, and even fainting. All which are generally signs and symptoms of the plague, which are of a more violent and quick operation in proportion to the virulence of the pestilential miasma.

This disease differs from other contagious, malignant, and eruptive fevers, because it is the most acute, and sometimes kills on the first, and sometimes on the second day. In our climate, it is not epidemic or sporadic, from a bad way of living or an unhealthy air, but happens when it is most salutary, from contagion alone, and is imported from hot countries where this disease rages. It will not only abate by intense cold, but be perfectly extinguished: wherefore, in a cold season and very cold countries, it either does not appear at all, or in a very mild degree; whereas if the climate is hot, it is not only most violent, but most common.

All plagues are not of the same nature, but vary according to different constitutions and circumstances; but all who have written of the plague universally agree, that spongy and porous bodies, of an obese habit, of a sanguine and phlegmatico-sanguine constitutions, women, young persons and children, persons of a timid disposition, that are poor, live hard, or are given to luxury, and sit up late at night, are more apt to be afflicted with this disease than the strong and intrepid, lean, nervous, endued with large vessels, men, old persons obnoxious to the hæmorrhoidal flux, and who have issues and open ulcers:

Nothing brings on this distemper sooner than fear, a dread of death, and a consternation of the mind. If the pestilential poison is not expelled to the external parts, it is certainly fatal; nor is this to be done, according to Hoffman, as in other fevers, by large sweats, by stools, by a flux of urine, by bleeding at the nose, either natural or artificial: for these threaten destruction. The salutary and critical excretion which perfectly solves the pestilential disease,

is by tumours in the surface of the body, not otherwise than the erysipelas, between the third and fourth day, and the sooner the better, because then the symptoms are mitigated. That there is poison contained in these tumours appears from hence, that if the surgeon opens any of the tumours with his lancet, and then bleeds a sound man with the same, he will be immediately seized with the plague. The pestilential tumours are of two kinds, the first arises in the glandulous places, most commonly in the groin and arm-pits; sometimes in the parotid and mammary glands, as also the lower maxillary, and in those near the aspera arteria.

**PLAGUE-WATER**, *Aqua Epidemica*, one of the compound waters of the shops, distilled from mint, rosemary, angelica-roots, &c.

**PLAIN**, *Planus*, in general, an appellation given to whatever is smooth and even, or simple, obvious, and easy to be understood; and, consequently, stands opposed to rough, enriched, or laboured.

A plain figure, in geometry, is an uniform surface; from every point of whose perimeter, right lines may be drawn to every other point in the same.

A plain angle is one contained under two lines, or surfaces, in contradistinction to a solid angle. See **ANGLE**.

The doctrine of plain triangles, as those included under three right lines, is termed plain trigonometry. See the article **TRIGONOMETRY**.

**PLAIN CHART**. See the article **CHART**.

**PLAIN SAILING**. See **SAILING**.

**PLAIN SCALE**. See **SCALE**.

**PLAIN TABLE**, in surveying, a very simple instrument, whereby the draught of a field is taken on the spot, without any future protraction. It is generally of an oblong rectangular figure, and supported by a fulcrum, so as to turn every way by means of a ball and socket. It has a moveable frame, which serves to hold fast a clean paper; and the sides of this frame, facing the paper, are divided into equal parts every way. It has also a box with a magnetical needle, and a large index, with two sights: and, lastly, on the edge of the frame, are marked degrees and minutes, to supply the place of a graphometer.

**PLAIN NUMBER**, is a number that may be produced by the multiplication of two numbers into one another: thus 20 is a plain number, produced by multiplication of 5 into 4.

**PLAIN PLACE**, *Locus Planus*, or *Locus ad Plannum*, among the ancient geometricians, denoted a geometrical locus, when it was a right line or a circle, in opposition to a solid place, which was an ellipsis, parabola, or hyperbola. These the moderns distinguished into loci ad rectam, and loci ad circumulum. See **LOCUS**.

**PLAIN PROBLEM**, in mathematics, is such a problem as cannot be solved geometrically, but by the

the intersection either of a right line and a circle, or of the circumferences of two circles; as, given the greatest side, and the sum of the other two sides of a right-angled triangle, to find the triangle; as also to describe a trapezium that shall make a given area of four given lines. Such problems can only have two solutions, in regard a right line can only cut a circle, or one circle cut another in two points.

**PLAINT**, in law, the exhibiting any action, real or personal, in writing. See the article **ACTION**.

**PLAN**, in general, denotes the representation of something drawn on a plane: such as maps, charts, ichnographies, &c. See **MAP**, **CHART**, &c.

The term plan, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot, into apartments, rooms, passages, &c.

A geometrical plan is that, wherein the solid and vacant parts are represented in their natural proportions.

The raised plan of a building, is the same with what is otherwise called an elevation, or orthography. See **ORTHOGRAPHY**.

A perspective plan, is that exhibited by degradations, or diminutions, according to the rules of perspective. See the article **PERSPECTIVE**.

**PLANCHIER**, or **PLANCERE**, in architecture, the under part of the corona, or drip, making the superior part of the cornice, between two cymatiums. See the articles **CORNICHE** and **CYMATIUM**.

**PLANE**, *Planum*, in geometry, denotes a plane surface, or one that lies evenly between its bounding lines: and as a right line is the shortest extension from one point to another, so a plane surface is the shortest extension from one line to another.

In astronomy, conics, &c. the term plane, is frequently used for an imaginary surface, supposed to cut and pass through solid bodies; and on this foundation is the whole doctrine of conic sections built.

**PLANE**, in joinery, an edged tool, or instrument for paring and shaving of wood smooth.

**PLANE-TREE**, *Platanus*, in botany, a genus of plants, producing male and female flowers. Botanists enumerate two species of these trees, one commonly called the oriental plane, and the other the occidental plane tree; the first sort grows naturally in many parts of Asia, where it rises to a very great size; the stem is tall, erect, and covered with a smooth bark, which annually falls off; it sends forth many side branches, which are generally a little crooked at their joints: the bark of the young branches is of a dark brown, inclining to a purple colour; these are furnished with leaves placed alternately, their footstalks are an inch and a half long, the leaves are seven inches long and eight

broad, deeply cut into five segments, and the two outer are slightly cut again into two more; these segments have many acute indentures on their edges, and have each a strong midrib, with many lateral veins running to the sides; the upper sides of the leaves are of a deep green, and the under pale. The flowers come out upon long footstalks, or ropes, hanging downward, each sustaining five or six round balls of minute flowers; they come out at the same time as the leaves; and in warm summers the seeds ripen late in autumn, and if left on the trees will remain till spring, when the balls fall to pieces, and the bristly down which surrounds the seeds helps to transport them to a great distance with the wind.

The occidental plane grows naturally in North-America; this tree also arrives to a great size; the footstalks are longer and the leaves larger than the other sort; they have several acute indentures on their borders, and are cut into three lobes or angles; the flowers grow in round balls, like the former, but are smaller. There are also two other sorts, called the maple leaved plane, and the Spanish plane-tree, somewhat differing from the others in foliage. The oriental sort was introduced into Italy in the early times of the Romans; their greatest men took much pleasure at their villas, which were surrounded with plane trees. Pliny affirms, that there was no tree whatsoever which so well defends from the heat of the sun in summer, nor more kindly admits it in winter, than this plant, the branches being produced at a proportionable distance to the largeness of their leaves; so that when the leaves are fallen in winter, the branches very easily admit the rays of the sun. And so much was this tree held in esteem by the people of Asia, that wherever they erected any grand buildings, the porticoes which opened to the air, terminated in groves of these trees. Plane trees are propagated from seeds, but principally by layers in this country, which will get rooted in a year, when they should be planted in a nursery for two or three years to get strength, and then transplanted where they are intended to remain.

**PLANET**, *Planeta*, *πλανήτης*, a celestial body, revolving round the sun as a center, and continually changing its position, with respect to the fixed stars; whence the name planet, which is a Greek word, signifying wanderer.

The planets are usually distinguished into primary, and secondary. The primary ones, called, by way of eminence, planets, are those which revolve round the sun as a center; and the secondary planets, more usually called satellites, or moons, are those which revolve round a primary planet as a center, and constantly attend it in its revolution round the sun. See **SATELLITE** and **MOON**.

The primary planets, are again distinguished into superior and inferior. The superior planets, are these

these further from the sun than our earth; as Mars, Jupiter, and Saturn: and the inferior planets, are these nearer the sun than our earth, as Venus and Mercury; for the astronomy, and other peculiarities, of which, see the articles MARS, JUPITER, &c.

*Nature of the PLANETS.* That the planets are opake bodies, like our earth, appears evident for the following reasons: 1. Since in Venus, Mercury, and Mars, only that part of the disk illuminated by the sun, is found to shine; and, again, Venus and Mercury, when between the earth and the sun, appear like dark spots or maculæ, on the sun's disk; it is evident, that Mars, Venus, and Mercury, are opake bodies, illuminated with the borrowed light of the sun. And the same appears of Jupiter, from its being void of light in that part to which the shadow of the satellites reaches, as well as in that part turned from the sun; and that his satellites are opake, and reflect the sun's light, is abundantly shewn. Wherefore, since Saturn, with his ring and satellites, only yield a faint light, fainter considerably than that of the fixed stars, though these be vastly more remote; and than that of the rest of the planets; it is past all doubt, he too, with his attendants, are opake bodies. 2. Since the sun's light is not transmitted through Mercury and Venus, when placed against him, it is plain they are dense opake bodies; which is likewise evident of Jupiter, from his hiding the satellites in his shadow; and therefore, by analogy, the same may be concluded of Saturn. 3. From the variable spots in Venus, Mars, and Jupiter, it is evident these planets have a changeable atmosphere; which changeable atmosphere may, by a like argument, be inferred of the satellites of Jupiter, and therefore by similitude the same may be concluded of the other planets. 4. In like manner, from the mountains observed in Venus, the same may be supposed in the other planets. 5. Since then, Saturn, Jupiter, both their satellites, Mars, Venus, and Mercury, are opake bodies, shining with the sun's borrowed light, are furnished with mountains, and encompassed with a changeable atmosphere; they have, of consequence, waters, seas, &c. as well as dry land, and are bodies like the moon, and therefore like the earth. *Q. E. D.*

And hence, it seems highly probable, that the other planets have their animal inhabitants, as well as our earth.

**PLANETARIUM**, an astronomical machine, so called from its representing the motions, orbits, &c. of the planets, agreeably to the Copernican system.

The planetarium is more generally known by the name orrery, and therefore we have given its description and use under that article. See ORRERY.

**PLANETARY**, something relating to the planets.

**PLANIMETRY**, that part of geometry which considers lines and plane figures, without considering their height or depth.

**PLANISPHERE**, signifies a projection of the sphere, and its various circles on a plane; in which sense maps, wherein are exhibited the meridians, and other circles of the sphere, are planispheres.

**PLANISPHERE**, is more particularly used for an astronomical instrument used in observing the motions of the heavenly bodies.

**PLANT**, *Planta*, is defined to be an organical body, destitute of sense and spontaneous motion, adhering to another body in such a manner as to draw from it its nourishment, and having power of propagating itself by seeds. As to the parts of which a plant consists, they are the root, stalk, branch, leaf, flower, and fruit; which see.

All botanists are of opinion that there is a certain analogy between plants and animals, since plants, like animals, are composed of certain parts, vessels, &c. each kind of vessel being supposed the vehicle of a different humour or juice, secreted from the matter of the sap, which is considered as the blood or common fund of them all: two things are to be considered in plants, viz. the sensible and organic body, and the spirit or the vegetative body, which is the cause of the whole motion, and the principle of all vital functions. The spirit or active substance, which obtains the name of soul in living bodies, is not even entirely excluded from things destitute of life, since the subtil matter being carried by a perpetual motion, runs through the whole corporeal nature; but as it is too much dispersed in bodies deprived of life, nor can find in them pipes and receptacles wherein it could be gathered in a greater quantity, thereby it could expel the humours it should meet with, and not produce in them those vital motions of nutrition and accretion; hence fossils and other inanimated bodies are of a longer duration, because not disturbed or worn out by that vegetative and active substance: but in plants, as well as in animals, the active spirit continually agitated by the subtil matter, runs without intermission throughout the whole body; and the more or less it is agitated, it wants a greater or less quantity of aliment, to avoid its feeding at last on the substance of the living body.

Plant and vegetable are nearly synonymous, every plant being a vegetable; which Boerhaave defines to be a body generated of the earth to which it adheres, and is connected with it by parts called roots, through which it receives the matter of its nourishment and increase, and consists of juices and vessels sensibly distinct from each other: or a plant is an organical body composed of vessels and juices every where distinguishable from each other, to which the roots grow, or parts by which it adheres to some other body, and from which it derives the matter of its life and growth. This definition is very scientific,

rific, and furnishes a just and adequate idea of a plant; for by its consisting of vessels and juices, it is distinguished from a fossil; and by its adhering to another body, and deriving its nourishment therefrom, and being destitute of sensation, it is distinguished from an animal; the mimosa, or sensitive plant, approaching the nearest to it. See FOSSIL, ANIMAL, and MIMOSA.

The vessels, or containing parts of plants, consist chiefly of earth bound or connected together by oil. In plants burnt by the intensest fire, the earth or matter of the vessels, is left intire and indissoluble by its utmost force; and consequently the matter thereof is neither water, air, salt, or sulphur, but earth alone.

The study of plants is both innocent and delightful; whoever applies himself to it will be soon agreeable surpris'd with the capacious field it opens for inquiry, where the human mind may range at large, and every day make fresh discoveries equally useful and entertaining. Now as every country hath its spontaneous plants, to raise and cultivate them in climates different from their own, requires much skill and art; for the plants of cold climates will not bear the heat of warm ones, any more than those of the warm can support the cold. Some of the Cape plants, in the heat of the torrid zone, grew at first amazingly, but soon after they lost their leaves, and were with difficulty kept alive: in this there is a considerable latitude to be allowed, for plants may be raised in a climate not their own, provided the difference is not very great; for by degrees they become as it were naturalized to it (this is evident in most of our culinary plants, fruit-trees, wheat, &c. which originally came from foreign countries) for if they produce seeds, these seeds are much less apt to miscarry, and produce hardier plants than such as are brought immediately from their native country. Now if we attentively consider the circumstances in which particular plants are spontaneously produced, we shall directly discover a sure and successful method of cultivating them by art. Linnæus justly observes, in a curious paper upon this subject, in the first volume of the Swedish acts, that the directions given in many books of gardening are founded merely on random practice; it being from wild plants alone that a rational method of culture can be deduced. He adds, that all plants grow somewhere wild, and that the business of art is to imitate their natural climate.

It was by following nature that the ingenious Botanist abovementioned has been so successful in bringing up the vast variety of plants that have fallen under his care. The *rubus caule unifloro foliis ternatis* was some time ago, he tells us, thought incapable of being raised about Stockholm, till attention to its natural climate taught him to keep it covered with snow during the winter and great part of the spring. The musa, or plantain tree, the

most specious plant in nature, had stood near an hundred years in the Dutch botanical garden, and could not be made to blow; but on considering it was a native of Surinam, where the weather is dry for near half the year, and rainy the next, it was kept long without water, and afterwards kept watered abundantly, which caused it to flower and perfect its fruit; and by the same management, another musa was made to flower the next year. For the botanical distribution of plants into classes, orders, genera, &c. see the articles BOTANY, GENUS, &c.

*Parasitical PLANTS.* See PARASITES.

*Sensitive PLANT.* See MIMOSA.

*Egg PLANT.* See MELONGENA.

*Fossile PLANTS*, those found buried in the earth, and lodged in almost all the kinds of strata, or substances, to be met with there.

PLANTA, in anatomy, the sole of the foot. See the article FOOT.

PLANTAIN, *Plantago*, in botany, a genus of plants, whose flower is monopetalous, with a cylindrically globose tube, and a depressed limb cut into four segments; the stamina are four erect, long, capillary filaments, topped with oblong, compressed, incumbent antheræ. The fruit is an ovate, bilocular capsule, containing many oblong seeds. The common broad-leaved plantain, which flowers in May or June, is a great cooler, and stopper of fluxes of all kinds, particularly hæmorrhages, whether from the nose, mouth, or uterus; it is likewise accounted a great healer of fresh wounds: the decoction is an excellent gargle in ulcers of the mouth; and, with lime-water, it cures ulcers in the legs: also made into an ointment, with fresh butter, it is said to cure the piles. Ribwort and bucks-horn plantain are of this genus, and agree with the common plantain in virtues.

PLANTAIN-TREE, *Musa*, in botany, a genus of plants, producing male and female flowers; the corolla of which is unequal and ringent; an erect, ligulated petal, cut into five indentures at the extremity, constitutes the upper lip, and a monophyllous, heart-shaped nectarium, the under one: the stamina are six subulated filaments, five of which are inserted in the petal, and the sixth in the nectarium, and double the length of the others; this is terminated with a linear antheræ, the others having none. The fruit is an oblong fleshy berry, covered with a thick rind.

The plantain-tree is cultivated in the West-Indian islands; it rises with a soft herbaceous stalk fifteen feet high, and upwards; the lower part is eight or nine inches diameter, diminishing gradually to the top, where the leaves come out on every side; these are often six feet long, and near two feet broad, having a strong fleshy mid-rib, and a great number of transverse veins running from it toward the edges: these leaves come out from the center of the

the stalk, and are rolled up at their first appearance; but when they are advanced above the stalk, they expand quite flat and turn backwards: when the plant is grown to its full height, the flowers will appear in spikes in the center, which are often four feet in length; on the lower part of the spike they are largest, diminishing in their size upwards; each of these spikes is covered with a sheath of a fine purple colour within, which drops off when the flowers open: the upper part of the spike is covered with barren flowers, which fall off with their covers. The fruit is about eight or nine inches long, and above an inch diameter, having three blunt angles, and is a little incurved; it is at first green, but when ripe, of a pale-yellow colour; the skin is tough, and within is a soft pulp of a luscious sweet flavour: the spikes of fruit are often so large, as to weigh upward of forty pounds each.

This fruit in the West-Indies is generally cut before it is ripe, and roasted in the embers and eaten by the negroes as bread. The leaves are used for napkins and table-cloths, and are likewise food for hogs.

Of this genus, the banana is a species. See the article BANANA.

PLANTARIS, in anatomy, one of the extensor muscles of the foot, which has its origin from the interior part of the external condyle.

PLANTATION, in the West-Indies, denotes a spot of ground, which a planter, or person arrived in a new colony, pitches on to cultivate for his own use, or is assigned for that purpose. However, the term plantation is often used in a synonymous sense with colony.

PLANTING, in agriculture and gardening, is setting a tree or plant taken from its proper place, in a new hole or pit; throwing fresh earth over its root, and filling up the hole to the level of the surface of the ground.

The first thing in planting, is to prepare the ground, before the trees or plants are taken out of the earth, that they may remain out of the ground as short a time as possible; and the next is to take up the trees, or plants, in order to their being transplanted.

In taking up the trees, carefully dig away the earth round the roots, so as to come at their several parts to cut them off; for if they are torn out of the ground without care, the roots will be broken and bruised to the great injury of the trees. When you have taken them up, the next thing is to prepare them for planting by pruning the roots and heads. And first, as to the roots, all the small fibres are to be cut off, as near to the place from whence they are produced, as may be, except they are to be replanted immediately after they are taken up. Then prune off all the bruised or broken roots, all such as are irregular, and cross each other, and all downright roots, especially in fruit-trees: shorten the

larger roots in proportion to the age, the strength, and nature of the tree; observing that the walnut, mulberry, and some other tender-rooted kinds should not be pruned so close as the more hardy sorts of fruit and forest-trees: in young fruit-trees (such as apples, pears, plumbs, peaches, &c.) that are one year old from the time of their budding or grafting, the roots may be left only about eight or nine inches long; but in older trees, they must be left of a much greater length: but this is only to be understood of the larger roots; for the small ones must be chiefly cut quite out, or pruned very short.

The next thing is the pruning of their heads, which must be differently performed in different trees; and the size of the trees must also be considered: thus, if they are designed for walls or espaliers, it is best to plant them with the greatest part of their heads, which should remain on till they begin to shoot in the spring, when they must be cut down to five or six eyes, at the same time taking care not to disturb the roots. But if the trees are designed for standards, you should prune off all the small branches close to the place where they are produced, as also the irregular ones which cross each other; and after having displaced these branches, you should also cut off all such parts of branches, as have by any accident been broken or wounded; but by no means cut off the main leading shoots which are necessary to attract the sap from the root, and thereby promote the growth of the tree.

Having thus prepared the trees for planting, you must now proceed to place them in the earth; but first, if the trees have been long out of the ground, so that the fibres of the roots are dried, place them eight or ten hours in water, before they are planted, with their heads erect, and the roots only immersed therein, which will swell the dried vessels of the roots, and prepare them to imbibe nourishment from the earth. In planting them, great regard must be had to the nature of the soil; for if that be cold and moist, the trees should be planted very shallow; and if it be a hard rock or gravel, it will be better to raise a hill of earth where each tree is to be planted, than to dig into the rock or gravel and fill it up with earth, as is too often practised, by which means the trees are planted as it were in a tub, and have but little room to extend their roots.

The next thing to be observed, is to place the trees in the hole in such a manner that the roots may be about the same depth in the ground, as before they were taken up: then break the earth fine with a spade, and scatter it into the hole, so that it may fall in between every root, that there may be no hollows in the earth: then, having filled up the hole, gently tread down the earth with your feet, but do not make it too hard, which is a great fault, especially if the ground be strong or wet.

Having thus planted the trees, they should be fastened to stakes driven into the ground, to prevent their

their being displaced by the wind, and some mulch laid upon the surface of the ground about their roots: as to such as are planted against walls, their roots should be placed about five or six inches from the wall, to which their heads should be nailed, to prevent their being blown up by the wind.

The seasons for planting are various, according to the different sorts of trees, or the soil in which they are planted: for the trees whose leaves fall off in winter, the best time is the beginning of October, provided the soil be dry; but if it be a very wet soil, it is better to defer it till the latter end of February, or the beginning of March; and for many kinds of evergreens, the beginning of April is by far the best season; though they may be safely removed at Midsummer, provided they are not to be carried very far; but you should always make choice of a cloudy wet season. *Miller's Gard. Diet.*

*Reverse* PLANTING, a method of planting, in which the natural position of the plant, or shoot, is inverted; the branches being set into the earth, and the root reared into the air.

Dr. Agricola mentions this monstrous method of planting, which he found to succeed very well, in most or all sorts of fruit-trees, timber-trees, &c. Bradley affirms, that he has seen a lime-tree in Holland growing with its first roots in the air, which had shot out branches in great plenty, at the same time that its first branches produced roots and fed the tree.

Mr. Fairchild, of Hoxton, has practised the same with us, and gives the following directions for performing it: Make choice of a young tree of one shoot, of alder, elm, willow, or any other tree that easily takes root by laying; bend the shoot gently down into the earth, and so let it remain till it has taken root. Then dig about the first root, and raise it gently out of the ground, till the stem be nearly upright, and then stake it up. Then prune the roots, now erected in the air, from the bruises and wounds they received in being dug up, and anoint the pruned parts with a composition of two ounces of turpentine, four ounces of tallow, and four ounces of bees-wax, melted together, and applied pretty warm. Afterwards prune off all the buds or shoots that are upon the stem, and dress the wounds with the same composition, to prevent any collateral shootings, that might spoil the beauty of the stem.

PLANTING, in architecture, the laying the first course of stones, in the foundations of buildings. See the article FOUNDATION.

PLASTER, *Emplastrum*, in pharmacy, is defined to be an external application, of a harder consistence than our ointments: these are to be spread according to the different circumstances of the place, wound, or patient, either upon linen or leather.

If the part upon which they are to be laid be naturally hairy, it must be shaved; but that they may

stick the better, the natural shape of the part must be consulted, and the plaster spread and formed accordingly, either round, square, triangular, elliptical, in a lunar form, or in the shape of the letter T. Some also are divided at both ends, and others are perforated in the middle; these last are of frequent use in fractures attended with a wound; for by this contrivance, the wound may be cleansed and dressed without removing the plaster.

These plasters are of different forms, according to the part they are laid on; but they are usually square, or round: and, indeed, there is almost no part of the body which a plaster, of one of those forms, may not be made to serve for, if it be notched about the edges with a pair of scissors.

The uses of plasters are various; they are serviceable in securing the dressings, they also forward the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, assuage pain, and strengthen weak parts.

The common plaster is made by boiling one gallon of oil-olive, with five pounds of litharge finely powdered, in about a quart of water, over a gentle fire, and continually stirring them, till the oil and litharge are united, and the whole acquires the consistence of a plaster.

The quicksilver-plaster is made thus: Take of the common-plaster one pound, of quicksilver three ounces, and of the simple balsam of sulphur a dram, and, lastly, let them be incorporated.

A cephalic is ordered by the college to be made of two pounds of Burgundy pitch, one pound of soft labdanum, and yellow rosin and yellow wax, of each four ounces; one ounce of what is called the expressed oil of mace: the pitch, rosin, and wax, being first melted together, add first the labdanum, and then the oil of mace.

A strengthening plaster is made, by adding to two pounds of the common plaster melted, half a pound of frankincense, and three ounces of dragon's-blood, both reduced to powder.

A drawing plaster is made thus: Take yellow rosin and yellow wax, of each three pounds; of tried mutton-suet one pound; melt all together, and strain the mixture for use.

The blistering plaster is made thus: Take of the drawing plaster two pounds, of cantharides one pound, of vinegar half a pint; the plaster being melted, a little before it hardens, sprinkle in the cantharides, reduced to a very fine powder; then add the vinegar, and beat all well together.

There are several other forms of plasters, for which we must refer the reader to the dispensatories.

PLASTER, among builders, &c. The plaster of Paris is a preparation of several species of gypsums, dug near Mont Maitre, a village in the neighbourhood of Paris; whence the name. See the article GYPSUM.

The best sort is hard, white, shining, and marblely;

bly; known by the names of plaster-stone, or par-get of Mont Maitre. It will neither give fire with steel, nor ferment with aqua-fortis, but very freely and readily calcines in the fire into a very fine plaster; the use of which in building, and casting statues, is well known. See the article *Stucco*.

As the modern taste runs greatly into plastering, it were to be wished that this art could be brought into its ancient perfection. The plasters of the Romans were exceeding durable; witness several yards of it still to be found on the top of the pont de Garde, near Nîmes. At Venice they use a very durable plaster; but, as the secret of preparing it is not known among us, it would be worth while to try whether such a substance might not be made, by boiling the powder of gypsum dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it rosin, or pitch, or both together, with common sulphur, and the powder of sea-shells. If these were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the instant of its being used, so that it might be laid on hot, it is possible this secret might be hit upon.
